Mr. A. W. ADAMS agreed with Mr. Short's observation as to duodenal ileus. He found this condition in one case diagnosed chronic appendicitis. He suggested that this condition might be associated with those cases of acute post-operative gastric dilatation, the mesenteric vessels being responsible.

Mr. SHORT, in reply, said that though duodenal ileus was difficult to diagnose before operation, in a typical case this was possible. He was glad others agreed that dyspepsia and hæmatemesis occurred as symptoms of appendicitis.

Diagnosis of Nasal Sinus Disease.

Dr. P. WATSON-WILLIAMS read a note on some points in the diagnosis of nasal sinus disease. He showed by what means, using the suction-syringe method of sinus exploration, it was possible to differentiate between cells. Especially might this become important when one sphenoidal sinus was very large and the other small; the large sinus might be entered from the opposite side of the nose in mistake for the sinus of that side, and the latter thus overlooked. In certain cases, notably those with involvement of vision, this might lead to serious errors in the diagnosis. The point was illustrated by a collection of lantern slides.

GLASGOW ROYAL MEDICO-CHIRURGICAL SOCIETY.

AT a recent meeting of this Society, Prof. ARCH. YOUNG, the President, in the chair, Dr. IAN STRUTHERS STEWART (Nordrach-on-Dee) spoke on some points in the

Diagnosis and Prognosis of Pulmonary Tuberculosis.

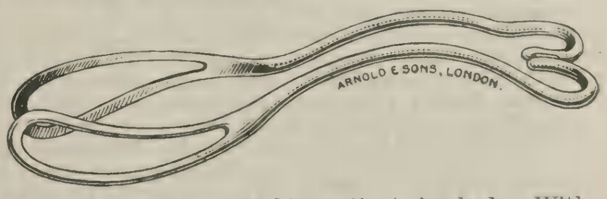
Dr. Stewart referred briefly to the pathology in relation to the infection and subsequent spread of the disease. The infection was at first one of the lymphatic system, and in the less acute cases the route might be through the tonsil to the cervical, mediastinal, bronchial glands, and thence by way of the peribronchial lymphatics of the larger bronchi to the lung, the sub-pleural lymphatics, and the visceral pleura. The inflammatory changes which took place in the bronchial wall as a result of the infection of the peribronchial lymphatics might be followed by caseation and ulceration into the lumen of the bronchus and infection of the lung, or by blocking of the lumen with subsequent collapse of the lung area supplied—a condition which favoured the further spread of the disease. Referring to the comparative frequency of the early signs and symptoms, Dr. Stewart gave the following percentages of frequency as a result of an analysis of 200 consecutive cases: Cough, 60; lassitude, 48; pyrexia, 42; hæmoptysis, 27·5; pleurisy, 24·5; loss of weight, 12; loss of voice, 8; night-sweating, 7; dyspepsia, 3·5; neurasthenia, 1. The grouping of these into toxæmic and localising symptoms served to emphasise the fact that the toxæmic symptoms—lassitude, pyrexia, loss of weight, night-sweating, indigestion, and neurasthenia—might appear before any physical signs could be detected. The importance of accurate observation of the temperature was urged and several illustrative charts were shown. The speaker went on to co-relate the signs and symptoms with the pathological changes. When the infection was spreading through the lung it might be that the only signs present were loss of expansion—more obvious above the nipple or in the axilla—with some faintness of breath sounds on one side. Narrowing of Krönig's area of resonance over one or both apices might be found or diminished tidal expansion at one or other base. Dullness was not usually demonstrable at this stage, but a few fine crepitations, audible only after coughing, under the clavicle or above or external to the nipple or in the interscapular region ought to be viewed with suspicion. As the swelling of the bronchial wall increased the breath sounds became harsh, and this harshness was more easily detected in inspiration. With the broncho-pneumonia dullness appeared, often more easily detected high up in the axilla. Broncho-vesicular breathing now appeared, becoming more bronchial as the consolidation increased. It was clear from a consideration of the pathology that to detect the earliest evidence of pulmonary tubercle both percussion and auscultation must be used in conjunction with systematic inspection and palpation. In conclusion, Dr. Stewart described the technique for the radiological examination of the lungs and referred to the important points in the interpretation of the appearances seen in an early case.

In the discussion which followed, Dr. E. F. M. MACGREGOR, Dr. J. A. WILSON, and Dr. FERGUS HENDERSON took part.

New Inventions.

IMPROVED ASSALINI MIDWIFERY FORCEPS.

I HAVE modified Assalini's forceps by adding a backward curve of the handles to give an axis-traction effect in the simplest possible manner. Traction is applied to the extreme end of the handles when the full value of the backward curve is obtained. The good points possessed by the original Assalini instrument appeal to the general practitioner, who conducts his confinements with his patient in bed. With Assalini forceps there need be no difficulty in passing the upper blade with the lower one already in place. The upper blade is passed first, horizontally in front of the sacrum and then rotated carefully into its proper position. The nurse can then hold it well back while the lower blade is passed into place. This manœuvre is not impossible with ordinary forceps, but to make it easy the lock needs to be reversed. Furthermore, the Assalini instrument entirely avoids the risk of compressing the head.



Messrs. Arnold and Sons (John Bell and Croyden, Ltd.), 50–52, Wigmore-street, London, W. 1, are the makers.

Reviews and Notices of Books.

THE STRUCTURE OF THE RED CORPUSCLE.

The Erythrocyte and the Action of Simple Hæmolysins. By Eric Ponder, Lecturer on Physiology in the University of Edinburgh. London and Edinburgh: Oliver and Boyd. 1924. With 11 text figures. Pp. 192. 12*s.* 6*d.*

This book should be read by everyone interested in red blood corpuscles, which, adding together only the hæmatologists and immunologists, means a good many people. Its aim is to discuss the old problem of the structure of the red cell, why it has its extraordinary shape, and what happens when it is swollen and shrunk and lysed by various agencies, and especially what light the study of hæmolysis throws on its essential architecture. There are publishers who would have delighted to describe Dr. Ponder's dissertation on these subjects on the book wrapper as a "he-book," for the vivid zest and certainty with which he criticises and mostly condemns those who have previously ventured into the field—himself included (pp. 149, 151)—will at least arouse those attacked to think hard.

There are two outstanding problems about the structure of the red cell. The first is why it is a biconcave disc instead of spherical, as all homogeneous bodies of that size floating in a liquid ought to be and try to be; the same question arises in an even more acute form when still smaller bodies, such as influenzoid bacilli, are concerned. It seems evident that the curious shape of the red cell, so admirably adapted to its function, must be due either to an internal architecture, which is equivalent to an arrangement of ties and struts, or to local differences in the outer skin, which lead to surface forces having local effects. The second problem is—what is the structure of the cell? On this a great many different views have been put forward, ranging from the extreme on the one hand that it is essentially like a piece of gelatin (Rollett *et al.*), to the extreme on the other hand that it is a bag filled with a solution of hæmoglobin (Schafer *et al.*). Dr. Ponder rightly recognises that no certain answers can yet be given to these questions and his lively discussion will help us to clarify our thoughts. The observation that saponin makes red cells swell up into spherical balloons just before they hæmolyse strongly suggests that the shape is maintained by some sort of structure under stress, which gives way at an early stage in the process of lysis. The facts of swelling and shrinking in different salt solutions and the established differential permeability are, as Dr. Ponder points out, really impossible to reconcile with any theory of structure which does not postulate a functional, if not a morphological, limiting membrane. Contrariwise, the view that we have a simple solution of hæmoglobin in a bag is hardly compatible with the extraordinarily interesting phenomenon of reversible hæmolysis described by G. S. Adair, J. Barcroft, and A. V. Bock, and more fully by R. Brinkman and A. v. Szent-Gyorgyi (the author fails to give the reference to the latter in his bibliography: it is *Journal of Physiology*, vol. lviii., p. 204). Dr. Ponder recommends us to remain doubtful on certain unproven questions, and in the end takes his own advice and comes to a tentative conclusion that the truth lies somewhere between the two extremist positions. A large part of the book is occupied with a detailed account of the quantitative aspects of hæmolysis, mostly from the author's own researches with saponin and bile-salts. The results are simple up to a point, and it will be a satisfaction to those who believe in general principles to find him strongly in favour of the proposition that the resistances of the cells are distributed according to the normal curve. Another point to which special attention may be drawn is his proposal that the setting free of hæmoglobin is only a first stage in, e.g., saponin hæmolysis, and that it is succeeded by a phase of considerably longer duration in which the stromata are also dissolved; the process ought to be looked at as a whole, especially if its nature is going to be identified by mathematical analysis. Lysis by distilled water is not followed by this "stromatolysis."

The book, then, contains much good information and stimulating discussion and, which is more important, provides abundant incitement to thought and fresh experiment. On broad lines we thoroughly recommend it and the series of biological monographs and manuals under the general editorship of Dr. F. A. E. Crew and Dr. Ward Cutler, of which this volume is the second, will do well if the present standard is maintained. In detail, however, there is much which is unnecessarily emphatic and a certain amount which is heedlessly inaccurate. If an author assumes a polemical and critical attitude, he does well to be rather over-nice about his own precision. The method, for instance, of measuring red cells used by C. Price Jones is dismissed as "valueless" (p. 15) and the deductions as "absurd" (p. 22); "the statement made by Price Jones that fixation with osmic acid leaves the cells unaltered in size is to be emphatically denied" (p. 15), which seems going to unnecessary trouble since Price Jones makes no such statement in the papers referred to nor, we think, in any other of his writings. In a later section (p. 162) Dr. Ponder considers the theories which have been put forward to account for the nature of the process of bacteriolysis. After disposing of Arrhenius, he notes that "no evidence is adduced in favour of the highly improbable assumption" about cyclical changes in bacterial resistance advanced by H. Chick (*Journal of Hygiene*, 1908, vol. vii., p. 92) and that the modification introduced by that author in a later paper (Ibid., 1910, vol. x., p. 237) "is less reasonable than the original view, if that were possible." In neither of these papers does Chick deal with bacteriolysis; they concern the killing of bacteria by heat and disinfectants; her observations on bacteriolysis will be found in the same journal (vol. xii., p. 414). Similarly, we read (p. 164), "Henderson Smith has shown that the phenomenon of bacteriolysis is to be explained" in a way that Dr. Ponder thinks reasonable; no reference to the original is given, but the well-known papers by Smith in the *Annals of Applied Biology* (1921, vol. viii., p. 27; 1923, vol. x., p. 335) are not about bacteriolysis, but concern the killing of *Botrytis* spores by chemicals and by heat. And this is immediately followed by the assumption that the killing of *Colpidium* by corrosive sublimate is so "similar" to bacteriolysis that it is germane to a discussion of hæmolysis.

THE PSYCHOLOGY OF EMOTION: MORBID AND NORMAL.

By John T. MacCurdy, M.D. Hopkins, M.A. Cantab., Lecturer in Psychopathology, Cambridge University. International Library of Psychology, Philosophy, and Scientific Method. London: Kegan Paul. 1925. Pp. 589. 25*s.*

Dr. MacCurdy when on the staff of the Psychiatric Institute of the New York State Hospitals was a colleague of the late Dr. August Hoch, whose work on "Benign Stupors" he completed for publication. The book under review continues the same theme, the psycho-analytic study of manic-depressive insanity, the conclusions as to the psychology of emotion being really a secondary product of the main research. Kraepelin's unification of the manic-depressive group is accepted, but his claim that the unity depends upon a constitutional disposition is vigorously attacked and Kraepelin is placed among "that stout-hearted little band of survivors from the period when psychology took no account of unconscious mental processes." The author enlarges the classification by introducing the reaction types of stupor, involution melancholia, anxiety and perplexity, and premises "the unknown, unconscious factor which leads to abnormal reactions." In the discussion of theories of emotion McDougall's views, widely accepted in this country, are severely handled; MacCurdy holds that emotional expression occurs when instinctive reaction is held up, that it may be limited to objectively observed expressions, and that only when the subject has self-conscious awareness is the emotion perceived as "affect." The Œdipus complex, he claims, is recognised by its effects and provides a hypothesis to cover a large range of phenomena, the apparently incoherent utterances of the insane, for example, acquiring coherence and relevance when they are assumed to be variations of this fundamental theme. The main part of the book consists of full case descriptions of the type reactions, and the important clinical point emerges that the appearance of infantile sexuality in a gross form is diagnostic of dementia præcox with its inevitable deterioration. Chapters on dreams link up morbid and normal psychology, and the main conclusion is that "Emotional expression is the product of unconscious images which stimulate involuntary behaviour, either overt or visceral, accessory to purposeful actions."

The book is difficult reading. Some of the difficulty may be personal to the reviewer, some belongs to the subject, but some arises from a lack of emphasis that makes the selection of essentials rather a task. In Chapter XI., for example, the author writes of "this formula," but the phrase refers to a page of dissertation which the reader would be grateful to see concisely summed up in anything resembling a formula. Nevertheless, the book is a record of painstaking and original work in a direction that promises to illuminate some of the fundamental problems of psychiatry.

THERAPEUTICS.

L'Année Thérapeutique. By Dr. L. CHEINISSE. Fifth year. 1924. Paris: Masson et Cie. 1925. Pp. 186. Fr.8.

THIS therapeutic annual consists of annotations from the medical literature of the previous year, and it reviews new methods of treatment adopted not only in France, but in all the principal countries of the world under the headings of "Maladies and Symptoms" and "Therapeutic Technique and Method." Within the limits of its size it can scarcely claim to be complete, but it does give a fair idea of the trend of therapeutics, as witness the number of diseases for which insulin is recommended in the present volume. Perhaps the most pleasant feature of this little book is the author's habit of referring to a writer he is quoting as "notre confrère." This is a personal touch which will unfortunately be missing from future editions, if such appear, for Dr. Cheinisse was killed in an accident in November, 1924, and an unfinished preface to this volume represents the last lines he wrote.

OPHTHALMOLOGICAL SOCIETY'S TRANSACTIONS.

Transactions of the Ophthalmological Society of the United Kingdom. Vol. XLIV. (Session 1924.) London: J. and A. Churchill. 1924. Pp. 452.

THIS annual publication maintains regularly or improves upon its own high standard. The present volume, besides the report of the annual congress held in May, 1924, includes a report of the Oxford Ophthalmological Congress which occupied three days of July, and comparatively short reports of the proceedings of the Midland, the North of England, and the Irish Ophthalmological Societies. A discussion on the physiology and pathology of the pupil reactions will be read with interest, the opening papers being by Sir J. H. Parsons, Prof. E. Bramwell, and Mr. R. A. Greeves. Other papers worth special attention are one on the practical applications of the slit lamp, by T. Harrison Butler and Basil Graves, and an important paper on the pathology of keratitis punctata, by M. S. Mayou. There is a useful discussion on ocular symptoms in subarachnoid hæmorrhage by Leslie Paton, and one on eye symptoms in the early diagnosis of disseminated sclerosis opened by Mr. Brownlow Riddell; a paper by Dr. Ivy Mackenzie on the trigeminal system as an integrating mechanism in disorders of the eyes; and finally one by Ida C. Mann on coloboma iridis and its embryology. This last is illustrated by 16 admirably clear figures.

At Oxford the chief subjects discussed were the general principles of the treatment of concomitant squint, the openers being E. Landolt, of Paris, and Ernest Thomson, and ophthalmology from a legal aspect, a subject which was presented by Mr. H. H. Joy, K.C., in a paper containing useful advice concerning evidence in eye cases in the law courts. Other items of interest discussed at Oxford were atypical retinitis pigmentosa (H. F. Hansell, of Philadelphia), chorio-retinitis juxtapapillaris (H. Friedenwald, of Baltimore), an important paper, one conclusion of which is that since the disease is not a separate clinical entity the term should be discarded. F. Park Lewis, of Buffalo, discusses the prevention of blindness as an organised movement, and George Young contributes a paper of interest in which his method of dealing with cases of chronic glaucoma is set forth.

Of the numerous contributions to the other societies, one of practical significance is by Bernard Chavasse on the need for correctly placed trial lenses and frames in testing for refraction.

THE ROUTINE EXAMINATION OF THE EYE.

By BASIL LANG, F.R.C.S. Eng., Assistant Surgeon, Royal London Ophthalmic Hospital (Moorfields). London: E. Arnold and Co. 1925. Pp. 156. 6s.

Mr. Basil Lang has done well to rewrite and expand this little book on the methodical examination of the eye published by his father 30 years ago, in a form suitable for the requirements of to-day. The student is advised to read it with the patient or a fellow-student in front of him, so that he may be able immediately to examine the part of the eye in question. This is sound advice. It will, for example, save much time to the student as well as a certain amount of discomfort to out-patients of hospitals, if such an elementary procedure as the eversion of the upper lid be thus learnt by pairs of students practising on each other.

The book is divided into three parts dealing respectively with the external examination, the subjective examination of the eye, and examination in the dark room. It is full of good points that reflect the practical ingenuity of the author. Thus, the method of demonstrating that the contraction of the pupil when an object is seen at close quarters is associated not with accommodation but with convergence, the method of testing the amount of proptosis with the aid of the perimeter and Harman's rule, the warning against a premature insertion of cocaine in cases of corneal ulcer before the corneal sensitivity has been tested, are all important points not to be found in the ordinary text-books. So is the explanation of the familiar fact that in testing for manifest hypermetropia the patient almost invariably accepts a higher convex glass with both eyes open than when one is shaded.

In a book like this we may expect to find some individual idiosyncrasies, and this applies to the recommendation to employ a retinoscope with a hole as large as 7 mm. in diameter. On referring to Mr. William Lang's book, published in 1895, however, we find the same recommendation. Some might cavil at the assertion that in all cases except squinting children a single instillation of a drop of 2 per cent. homatropine and cocaine produces substantially complete mydriasis and cycloplegia in 40 minutes. We think that the statement needs some further qualification, but that it is to be preferred to the insistence on the use for adult patients of atropine which was formerly too often prescribed unnecessarily.

We believe that this book will be popular.

HOW IT WORKS.

Yourself and Your Body. By WILFRED T. GRENFELL, M.D. Oxf., C.M.G., Superintendent, International Grenfell Association, Labrador. London: Hodder and Stoughton, Ltd. 1925. Pp. 317. *7s. 6d.*

Dr. Grenfell's two sons, he tells us in the preface to this admirable book, had reached "the age of ten million Whys? and Hows? and Whens? and Wheres?," so he took the advantage of a holiday to explain to them in simple language the way our bodies are made and how they work. This book is the result of these talks. In an interesting and amusing manner which any child can understand, Dr. Grenfell describes the principles of anatomy and physiology, everywhere illustrating his statements with pictures drawn by himself in which a bearded and unkempt fisherman (himself) and two thoroughly amused boys build up an imaginary body and conduct physiological experiments in a primitive fashion. The author appears to be rather worried lest the fundamental and necessary conception underlying the book—namely, that "an Ego controls the reactions of life through pyramidal cells, as press buttons"—be looked upon as a "menace to progressive scientific thinking." But if the book succeeds, as in our opinion it does, in inculcating in the minds of those who read it a healthy view of life as a result of sound knowledge of their bodies, surely metaphysical questions will be all the better approached when they arise in later life? At any rate, we rather envy Dr. Grenfell's sons, for if they enter their father's profession their early student days will be much easier and much more entrancing as a result of the knowledge obtained in childhood. We predict that grown-ups who buy this book for their children will dip into it with curiosity and then read it from cover to cover at the earliest opportunity. The only criticism that can be offered is that the author does not attempt the task of entering fully into the questions of sex and reproduction. He only touches on the fringe of these subjects, but the way in which he has successfully tackled the rest of physiology makes it probable that he is capable of solving the difficult problem of "how to tell our children."

Reports and Analytical Records.

ÆTHER PURISS, B.D.H.

(THE BRITISH DRUG HOUSES, LTD., CITY-ROAD, N. 1.)

THIS preparation is offered as a new and distinctive quality of absolute ethyl ether. When analysed the following results were obtained:—

Specific gravity	721·0°
Boiling-point range	34·6° to 37° C.

Furfural and methyl compounds were absent, but a minute trace of peroxide was detected when the ether was submitted to the B.P. potassium iodide test. When freshly prepared this is probably a very pure form of ether.

ANTISEPTIC SURGICAL SPIRIT.

(DUNCAN, FLOCKHART AND CO., EDINBURGH AND LONDON.)

This spirit is prepared from industrial methylated spirit and has been treated with denaturants of a harmless character. It is claimed to overcome the difficulty of pyridinised methylated spirit and it may be used for all purposes where the commercial methylated spirit would have been indicated. When examined the spirit was found to be of a pale yellow colour and with a pleasant odour.

Alcohol content	87·5 per cent. by volume.
Denaturant	2·24 " "

The denaturant was a balsam-like substance, very bitter to the palate, and causing a precipitate when the spirit was mixed with water.

BILLOWZONE.

(BILLOWZONE, LTD., 8, SHERWOOD-STREET, PICCADILLY, W. 1.)

Billowzone is a saline preparation which, when dissolved in an appropriate amount of ordinary water, produces a solution said to resemble sea-water. It is claimed that when this solution is exposed in a room its exhalations have a revivifying effect on the atmosphere, resembling, in this respect, sea air.

When analysed the salt was found to have the composition:—

Sodium chloride	98·3 per cent.
Moisture	0·9 "
Matter insoluble in water	0·34 "

The solution had a faint blue tinge due to the presence of a minute amount of colouring matter and an odour certainly suggestive of the sea beach. No gas was liberated when the salt was dissolved in water. It may be pointed out that sea salt contains salts other than sodium chloride, and the proprietors claim the presence of nascent iodine. The preparation has been found useful in parasitic skin diseases and in various forms of tonsillar and pharyngeal catarrh.

SPECIAL IMPERIAL DRY CIDER (PRIORY BRAND).

(JOSEPH M. PARRY AND CO., LEOMINSTER.)

When analysed this cider gave the following results:—

Present specific gravity	1004·54°
Original gravity (before fermentation)	1044·72°
Alcohol	5·18 per cent. by volume.
Total sugar as invert sugar	1·73 per cent.
Volatile acidity (as acetic acid)	0·01 " "
Fixed acidity (as malic acid)	0·48 " "

The cider was examined for sulphurous, salicylic and benzoic acids and β-naphthol with negative results in each case. The cider was dry in flavour and fully fermented as the small amount of sugar present shows. It was agreeable to the palate, had a pleasant bouquet, was very bright, and in good condition.

DE KUYPER'S SCHNAPPS (SCHNAPPS AROMATICO).

(AGENTS: MESSRS. MATTHEW CLARK AND SONS, LTD., 14, TRINITY-SQUARE, LONDON, E.C. 3.)

Schnapps is the Dutch form of gin. It is a spirit distilled from grain flavoured with juniper berries and other herbs and again distilled. The sample, when analysed, gave the following results:—

Specific gravity	942·28°
Alcohol per cent. by volume	45·74 per cent.
Alcohol per cent. as proof spirit	86·06 per cent.
Equivalent to	19·94 per cent. under proof.
Extractives	Nil.

	Milligrammes per 100 c.cm. of absolute alcohol.
Volatile acidity	3·9
Fixed acidity	Nil.
Furfural	Trace.
Aldehydes	Trace.
Esters (as ethyl acetate)	38

No trace of sugar was found. It will be noted that this spirit is considerably above the legal limit for alcohol content of gin in this country—viz., 30 under proof. De Kuyper's Schnapps is a very pure form of potable spirit, possessing a mild and agreeable flavour.

THE LANCET.

LONDON: SATURDAY, MAY 2, 1925.

THE LEGAL RESPONSIBILITY OF THE SURGEON.

Lord Riddell's interesting and suggestive paper upon the above subject, read before the Medico-Legal Society,[1] serves, as he observed, to remind us that we live in times of changed aspirations and needs, or imagined needs. Some of those aspirations have been caused, and the imagination of men and women has been stimulated, by changes and progress in medicine and surgery inconceivable by those who in days long gone by moulded the common law and passed statutes for the protection of the bodies of their fellow subjects. "Maiming" to them was "such a hurt of any part of a man's body whereby he is rendered less able in fighting to defend himself or to annoy his adversary."[2] It was punishable as an act that a violent and lawless man would commit upon his neighbour, rather than as one which would be done upon a consenting party. Voluntary maiming, however, was not unknown, and a statute made it a felony for a man to maim himself in order to have "a more specious pretence for asking charity." The altered conditions now confronting us arise out of the possibilities of modern surgery and the temptations offered by changed and changing social conditions. In considering these possibilities and temptations in relation to the medical profession, Lord Riddell rightly, we think, declared that his main purpose was to draw attention to the situation in regard to the sterilisation of men and women arising out of modern teaching in eugenics, and out of modern views as to the limitation of families. He touched also upon the question of "cosmetic operations" performed in beauty parlours, but these we are inclined to associate with the activities of unqualified impostors, rather than with the efforts of the medical profession to preserve the physical charms of elderly women and men. The principles involved, however, include those governing the position of a surgeon asked to perform any operation not necessary for conserving or improving the bodily health of the person seeking it. Apart from the possibility of mutilation being sought with a view to soliciting charity, our forefathers seem to have usually provided only for the punishment of assaults inflicting "grievous bodily harm," for which graded penalties are now provided, the essence of an assault being the absence of consent by the injured party. What, then, is the position of a surgeon performing an operation which to him and to all but the person seeking it appears unnecessary, whether prompted by vanity, eccentricity, the desire to avoid the bringing children into the world, or any other motive not established as adequate?

Lord Riddell suggests, with particular relation to beauty parlours, the possibility of sepsis and death following an operation, with a prosecution for manslaughter as a sequel. This appears to us a reasonable test, subject to the observation that if an unnecessary operation were held to have had as its object the "maiming" of the deceased and to be in law a felony, the charge might be one of murder. Otherwise we may take it as a general proposition applicable to the question that "the essential feature in manslaughter is the unlawful (as opposed to felonious) doing of an act, or culpable neglect of a duty whereby the death of another is caused."[3] The word "unlawful" to lawyers does not mean necessarily the same as "illegal" or "criminal." Carnal knowledge, for example, of a woman or girl by a man not married to her is "unlawful carnal knowledge," but is contrary to law and punishable only in certain circumstances. The question therefore would seem to be whether any operation performed by a surgeon is to be deemed lawful, to which the wish of the patient, backed perhaps by the consent of his or her relatives, has been given. Lord Riddell would answer in the negative, having considered the matter in the light of the law, as laid down by various authorities, and we believe him to be right. He has dealt in particular with the question of deliberate sterilisation, whether of those mentally and physically sound, or of those mentally defective or diseased persons who are likely to produce undesirable citizens. He looks upon the medical welfare of the patient as the test to be observed, and believes an operation, the sole object of which is to prevent the subject of it from having children, to be clearly illegal. In the discussion which followed Lord Riddell's paper, prominence was given to the narrower topic of the sterilising of the mentally defective, and reference to our report will show that among those that spoke Sir William Willcox and Prof. Louise McIlroy declared themselves against the recognition of such an operation as desirable; Sir Charters Symonds urged that the public had a right to express an opinion on the subject, his own view being in favour of the establishment of the practice. None of them suggested that such a thing could be done in the present circumstances merely with the consent of the relatives, coupled perhaps with such consent as the patient might give. Parliament, we would add, might conceivably consider a Bill on the subject, but although everyone admits that the production of children by the mentally defective and other undesirable parents is prejudicial to the public welfare, it is, to say the least, doubtful whether public opinion, either now or in the near future, would sanction compulsory measures to render it impossible. And if public opinion would condemn the sterilisation of human beings in order to prevent the procreation of diseased offspring, it would presumably disapprove of the sterilisation of the healthy to suit their whim or their convenience.

The fact, however, that mentally defective persons cannot give a valid consent to anything on the face of it detrimental to themselves, places their case outside the general class of unnecessary operations, which a surgeon may be asked to perform upon persons able to decide for themselves and to indicate their wishes. The test there appears to be in law, whether the operation is or is not prejudicial to the public good. The individual may wish a certain thing to be done upon his body which, he thinks, will affect himself alone, but it may be contrary to public policy, if it renders him a less whole-bodied citizen. With this view the medical profession should wholeheartedly agree. It was held many years ago that "mala praxis is a great misdemeanour and offence, whether for curiosity or experiment or by neglect, because it breaks the trust which the party has placed in the physician tending directly to his destruction."[4] What Dr. Groenvelt did in this case is not recorded, but the "trust of the party" in the physician suggests the question whether a great trust is not placed in the medical man by the State when it confers on him certain privileges in virtue of his qualifications. It is submitted that the duties and rights assigned to him, from which others are excluded, were not devised merely as a reward for the acquirement of a prescribed amount of mental and manual dexterity, but in order to secure for the nation skilled treatment in time of physical need. It is not intended that skill so recognised by the State should be employed for gain, or even gratuitously, without there being any condition in the subject of its employment to demand it. The performance by a surgeon of an unneeded operation, appreciably injurious to the human body, at the request of an individual, should therefore be looked upon as contrary to public policy, and Lord Riddell appears to have demonstrated that it is also illegal and, in conceivable circumstances, punishable.

LESSONS OF A FOOD POISONING OUTBREAK.

The outbreak of illness following the mayoral banquet at Portsmouth last November, like the similar outbreaks at Winchester and Southampton in 1902, has been traced to oysters. The epidemiological side of the outbreak was worked out with great care by Dr. A. Mearns Fraser, the medical officer of health, and a careful analysis of the food eaten incriminated the oysters. Of the 83 persons who were promptly ill 82 had partaken of oysters, while the remaining guest who ate them was ill subsequently with an attack of diarrhœa lasting five days, but this was not until 14 or 15 days after consumption. 135 persons were present at the banquet, so that 61·5 per cent. suffered from some degree of illness within the next few days. In most cases the symptoms experienced were of the ordinary food poisoning type, such as diarrhœa, colic, vomiting, headache, feverishness and malaise. The incubation period is not set out in detail, but five were ill the same night, 35 next day, and 31 on the day following. Three of the cases are stated to have developed definite attacks of paratyphoid fever of a severe type. None of the oysters was available for bacteriological examination, but the layings from which they were said to have been obtained were ascertained and oysters from these layings were examined by Prof. J. W. H. Eyre. Those from one laying were reported contaminated, and Dr. Fraser remarks that the bacteriological results indicate, according to the standard now generally adopted, that such oysters are not fit for consumption, and would not be allowed upon the London markets. The oysters eaten were brought to the table direct, without having been relaid.

Unfortunately, the outbreak was very inadequately investigated on the bacteriological side, so that it is not possible to arrive at any conclusion as to the nature of the infection. As usual, none of the infected food eaten was available for examination, but no bacteriological examinations of materials from patients seem to have been carried out. A study of the symptoms and of the outbreak generally suggests infection with a living bacillus of the Salmonella type. An examination of excreta samples, and particularly of serum from a number of the cases, would probably have been adequate to settle the diagnosis, or at least to refute this probability. Agglutination tests, using the appropriate strains, of blood from patients have proved valuable in other outbreaks, and these could have been taken a week or more after the event. Three cases are definitely reported as paratyphoid fever, and while this appears likely from the clinical course, the bacteriological data are inconclusive. If, as appears probable, the outbreak was due to some Salmonella strain such as *B. aertrycke*, these cases would give a positive Widal agglutination reaction with *B. paratyphosus* B, and a differential diagnosis could only be made by the use of special specific type strains or by absorption tests. The exact nature of these outbreaks of illness from shellfish is still obscure, and it is somewhat unfortunate that more complete steps were not taken to utilise this outbreak to throw light upon the obscurity.

In addition to the importance of detailed bacteriological investigation of all food poisoning outbreaks, particularly of abnormal type, if they are to be prevented in the future, this outbreak also again directs attention to the need for more supervision over oyster beds. Dr. Fraser, discussing the prevention of future outbreaks, suggests that the remedy lies with the individual, and not with the health authority, and that the one safeguard of the public is to purchase oysters only from firms which guarantee their oysters to have been supplied from layings which have been inspected and approved by a competent authority. This seems rather hard on the individual and particularly inapplicable to the present outbreak, since each guest could hardly demand a health certificate with the oysters put before him. While this may be the only protection under existing conditions it is an unsatisfactory protection. Public health administrative machinery exists to protect the individual, and the proper course would seem to be only to allow oysters to be sold from layings which have been registered with and approved by an appropriate authority, or if the oysters have been relaid in approved places. This would require an alteration in the present law.

◆

THE ANATOMICAL DISTRIBUTION OF OCCUPATIONAL CANCERS.

It has long been known that in chimney-sweeps cancer of the scrotum is particularly frequent. The important work of Dr. Alexander Scott [1] on the occupation dermatoses of the paraffin-workers of the Scottish shale-oil industry, which is based on clinical observations extending over 24 years and for the publication of which we are indebted to the Imperial Cancer Research Fund, has revealed a similar selectivity of the anatomical site of "paraffin cancer." Here a curious difference has been noted by Dr. Scott. Those men who come most into contact with the paraffin oil develop on the arms and hands diverse forms of dermatitis, which may eventually develop into carcinoma, while cancer of the scrotum is relatively rare. Thus, out of 19 cases of carcinoma, 12 were on the hands and arms and only three on the scrotum. But cancer of the scrotum occurs with relative frequency among workmen in other departments of oil-works, although these men are not engaged in occupations which entail prolonged contact with or handling of oil. It affects particularly those men who, as retort men, labourers, or stillmen, come into contact with ash, coke, dust, or other gritty material. Thus in 46 cases of cancer occurring among such men, 28 were cancer of the scrotum. Another difference is that this type of cancer is not preceded by warts or papules, but arises as a primary lesion. This problem of the anatomical site of the lesion forms the subject of a recent paper by Dr. E. L. Kennaway [2] entitled the Anatomical Distribution of the Occupational Cancers, in which he presents a valuable collection of statistical data covering the various occupational cancers. All these conditions present a definite site of election. Thus two-thirds of all the pitch cancers occur either in the cheek, lip, and eyelid or on the scrotum, while other parts which are quite as much exposed to pitch dust, such as hand or fingers, are but very seldom affected. In the closely related cancer due to soot—i.e., chimney-sweep's cancer—only the skin of the scrotum shows a special liability to cancer, while cancer of the face and neck is rare. Thus out of 29 fatal cases of cancer in chimney-sweeps, 27 were on the scrotum and only two on the face and neck. In mule-spinners the scrotum is, again, the site of election, although the penis and a wide area of skin on the abdomen and on the thighs is equally exposed to the action of oil. In aniline-dye workers cancer develops almost always on the bladder and on the posterior wall of it; the kidneys and ureters are only rarely affected. In persons taking arsenic it is the fingers, legs, and the trunk which are the most frequent site of cancer, while the head, neck, and scrotum were affected in only 23 per cent. of all cases.

---

[1] Eighth Scientific Report of the Imperial Cancer Research Fund. London: Taylor and Francis. 1923. P. 85.

[2] E. L. Kennaway: Jour. Indus. Hyg., 1925, vii., 69.

For some of these curious phenomena a plausible explanation is suggested. Thus the restriction of the lesion to the bladder in aniline workers may be due to the carcinogenic substance being produced in the bladder from a precursor secreted by the kidneys in the urine. Again, Dr. Kennaway has shown that some organic substances which by themselves do not produce cancer experimentally acquire this property when passed through a red-hot tube, so that aromatic condensation products are formed, and this might explain why the workmen in oil-works who come into contact with the heated distilled products are particularly liable to be affected. But the particular liability of the skin of the scrotum to certain forms of occupational cancer remains a mystery. Neither the rugosity of the skin, which is usually given as an explanation by assuming that it facilitates the collection of dirt between its folds, nor the abundance of sebaceous glands affords an adequate explanation. In such occupations as coal-miners and agricultural labourers cancer of the penis is much more frequent than cancer of the scrotum, while in occupational cancer the ratio is reversed. It cannot even be maintained, therefore, that the skin of the scrotum is more liable to cancerous degeneration. In fact, for some countries (China, Ceylon) where cancer of the penis is relatively common, no records of cancer of the scrotum have as yet been obtained. It is desirable, therefore, that in all statistical statements cases of cancer of the scrotum and of the penis should be recorded separately and not be included under any common heading, for they seem to be quite different in origin. This is a good illustration of the great variety of factors concerned in producing the same pathological entity, epithelioma, in closely related anatomical positions.

The paper is full of valuable statistical data, and they are presented in such an interesting way as to make the dry bones of statistics live. The narrative reads almost like a detective story, but one in which the detective gets decidedly the worst of it. It is, no doubt, only the first instalment of a serial which will not come to an end before the culprit is brought to book. Perhaps the clinical observations of Sir Lenthal Cheatle on the relation of innervation to cancer, which have quite recently received experimental confirmation by the work of Dr. W. Cramer,[3] may offer a clue.

Annotations.

"Ne quid nimis."

FINE POINTS AND FIRST PRINCIPLES.

A COMPELLING candour causes us to recognise that the principle that public expenditure involves public control is not always remembered by those of us who tread the thorny paths of criticism. We are forcibly reminded of the fact from time to time by the Minister of Health and his advisers in connexion with the administration of the National Health Insurance Act, and Dr. R. A. Bolam and his colleagues appearing before the Royal Commission this week and next are under no illusions on the subject. There is another principle which is to be found amongst those scheduled as fundamental in the official statement of evidence being put before the Commission on behalf of the medical profession. It avers that with the administration of any health insurance scheme medical representatives must be closely associated. We have one or two comments to make on this subject in relation to the evidence of the society, familiarly known as the NIBS.

The N.I.B.S., or National Insurance Beneficent Society, has placed before the Commission the information and statement of its views which we summarise in this issue. One of the joint secretaries, Mr. P. Rockliff, is in another capacity the secretary of the Joint Committee of Approved Societies, and is spokesman for a very considerable body of approved society opinion. We confess to some impatience with the implications in the evidence of the Beneficent Society that the actions and motives of professional men are governed by sordid considerations, from whose direful effects on the simple-minded insured person the society stands ready to offer the protection of its beneficent wing. These implications are to be observed in the references to the transfer of a fee from the pocket of the needy claimant for dental benefit to the pocket of the doctor giving the requisite certificate, and to the proposed fee of 1 guinea to an ophthalmic surgeon for an examination for spectacles on the mere 5 per cent. chance of a serious disease of the eye, and in the suggestion that the dental profession would put before the Commission a Machiavellian scheme. This scheme, apparently, in the fair garb of economy, would limit dental benefit to extractions and so produce a toothless membership of approved societies, who would then be forced to clamour for dentures, cost what they may. Such a conception of the attitude of professional opinion towards health insurance developments is not calculated to remove that distrust of lay control—and especially of approved society control—which was so deep-rooted when, in 1911, the medical profession determined that, so far as medical benefit was concerned, they would not have it, at any rate without a powerful dilution of medical representation. The very large body of society opinion in favour of devoting surplus funds to "treatment" benefits rather than "cash" benefits renders it of increasing importance to see that the principle embodied in Section 14 of the National Health Insurance Act, 1911, in regard to benefits "in the nature of medical benefits," is not lost sight of; such benefits are to be excluded from administration by approved societies. It is just that principle which the constitution of the National Insurance Beneficent Society appears to controvert.

We have referred to the protecting wing of the society. It has in fact two wings. With the technicalities by which its incorporate side and its unincorporate side are created we are not concerned. Nor are we entitled to complain that it has been found possible within the limits of one or more Acts of Parliament to construct a charitable body to which societies and their members may subscribe, and a piece of machinery which enables approved societies, through an agent, to administer treatment benefits, unless we wholly misconceive the content of the word "administration." We can, indeed, allow ourselves to admire the ingenuity of the scheme. What concerns us most is the fact that out of the surpluses of approved societies, treatment benefits—which are "in the nature of medical benefit"—are in danger, to an increasing extent, of being administered in a way contrary to the intentions of Parliament. While the NIBS may not inappropriately be concerned with fine points, we are a little more concerned with the application of first principles.

EARLY MOVEMENT AFTER ARTHROTOMY AND ARTHROPLASTY.

WRITING in the *Presse Médicale* of April 1st, Dr. E. Desmarest discusses the lessons learnt from operating on three cases of ankylosis of the knee by the method of arthroplasty with free fascia-flaps. He lays stress on the importance of operating as early as possible after active disease has ceased, for the reason that muscular atrophy from disuse constitutes a very serious drawback to functional recovery. The very fact of the success of the operation, when strong and active muscles are able to control the joint in the complete absence of the usual ligaments, is evidence of the importance of a consideration of the state of the muscles. Dr. Desmarest follows Murphy more than Putti in his operative technique, prefers a U-shaped incision, and either divides the ligamentum patellæ or detaches it together with a thin scale of bone from its attachment to the tibia. Early massage and active movement he considers essential if a good result is to be attained. The patient should be encouraged to begin active movements in the joint almost as soon as he recovers from the anæsthetic. Dr. Desmarest gives as contra-indications to arthroplasty damage to the muscles of the thigh from osteomyelitis, old septic war injuries, with muscular atrophy and lesions of motor nerve trunks. Ankylosis from tuberculous disease is not suitable and the extremes of life should be avoided. In a communication to the *American Journal of Surgery* for March, Dr. Allen O. Whipple, of New York, strikes a like note in discussing the after-treatment of cases of arthrotomy. When this operation has been performed for loose bodies, displaced menisci, or acute non-purulent synovitis, the author strongly advocates early active movements as having a most beneficial influence on the end-result. But where large incisions have been made more caution and considerable delay are advisable. If considerable trauma has been necessary in the joint surface or structures, or if there are hypertrophic arthritic changes, immobilisation for a variable time is indicated, as it is in cases of great relaxation of the capsule.

ROEHAMPTON HOUSE.

OLD buildings do not, as a rule, make good hospitals, but Roehampton House, the extensions to which will be opened by the Queen on Wednesday next, May 6th, holds a place of its own in hospital history and economy. It had already stood, facing Richmond Park, for more than two centuries when in June, 1915, it became one of Queen Mary's Convalescent Auxiliary Hospitals. This stately and distinctly pleasing house was designed for a certain Mr. Thomas Cary, of whom next to nothing is known, by Thomas Archer, one of the aristocratic amateur architects of his day, who almost at the same moment was at work upon what is admittedly his most admirable achievement, the Church of St. Philip at Birmingham, which has now been raised to cathedral dignity. The influence of Vanbrugh is visible in both buildings, and Sir James Thornhill was brought to Roehampton to embellish a part at least of the interior. Apparently he did not get beyond the room over the entrance hall, but with that he dealt very thoroughly, painting the ceiling with the Feasts of the Gods, and covering the walls with landscapes. This work, which still endures, is not matched elsewhere for, in the main, the house is plainly panelled in painted deal. Roehampton House has had many owners and tenants, among them Dr. Markham, Archbishop of York, and latterly it was the abode of the Earls of Leven and Melville, by one of whom it was sold to Mr. A. M. Grenfell, who called in Sir Edwin Lutyens to make additions to it which nearly trebled its size, but the hospital was established there before he was able to decorate the interior of the new portions. For the immediate purpose of the hospital—the replacing by artificial means of the lost limbs of men maimed in the war—a number of wooden huts were erected, most of which have now been superseded by permanent wards of brick. There are five of these wards, each of which contains 40 beds—low, verandahed buildings connected by covered corridors. They face south and have for prospect a pleasant lawn. An operation block with two theatres and wards for electro-therapy form part of the new equipment, and in another corner of the grounds are the workshops which are busily turning out those cunningly articulated limbs which we have now learned to make with such astonishing skill and ingenuity. The inmates of the Special Surgical Hospital at Shepherd's Bush have been, or are in process of being, removed to the infinitely more restful and agreeable verge of Richmond Park, where there will be room for between 1100 and 1200 of them. Queen Mary's Convalescent Auxiliary Hospital at Roehampton will, however, no longer exist exclusively for the good of ex-soldiers and sailors. Men who are injured in limb on the railways will also be treated there, and, no doubt, eventually the victims of mining and other dangerous trades likewise. It may safely be claimed that, for its special purpose, there is no hospital in the world which excels Roehampton House, and probably nothing that equals it.

SANOCRYSIN IN TUBERCULOSIS.

RECENT reports from Denmark show that there too[1] the treatment of tuberculosis with sanocrysin is still in the experimental stage, and that such important matters as the dosage and the selection of suitable cases are still in debate. With regard to the dosage, there seems to be a general tendency towards giving smaller quantities and spacing them with longer intervals than those recommended by Prof. Möllgaard. The history of krysolgan treatment—the gold preparation which figured so largely in German medical publications a few years ago—shows the same downward graduation of the dosage in response to cases of serious poisoning, and it may be that krysolgan fell into disuse partly for this reason. In the case of sanocrysin it appears that such doses as 1 and 1·5 g. have been found often to be too toxic, both on account of the "tuberculin" action of the drug, and also because of direct metallic poisoning, the signs of which closely resemble those of sublimate poisoning. In some institutions in Denmark the initial dose of an intravenous injection has been reduced to 0·125 g. and even to 0·05 g. An interval of a week is sometimes allowed even when there is no severe reaction, and much caution is exercised in increasing the dosage. It has been argued that small doses at long intervals are dangerously timid; the vulnerability of the tubercle bacillus to the drug may, it is said, become lost. But on this point we have assuredly not yet heard the last word, and at present we do not even know with certainty what processes are at work when tuberculous tissues react to sanocrysin. It is, indeed, doubtful if the good effects hitherto achieved are due solely to the direct action of sanocrysin on the tubercle bacillus as studied in vitro. At all events there can no longer be any doubt that many of the ill-effects following an intravenous injection of sanocrysin are due to gold poisoning, pure and simple, and in a recent publication Dr. O. Scheel[2] has recorded a fatality of considerable interest in this connexion. The patient was a woman who died two days after the fourth injection of sanocrysin, of which a total of 3·5 g. had been given. Shortly before death she suffered from anuria and cyanosis, but there was no fall of temperature, nor evidence of a focal reaction in the lungs. The post-mortem examination showed hyperæmia of the colon, hæmorrhages in the small intestine, and severe parenchymatous disease of the kidneys. The absence of a fall of the temperature and of clinical signs of œdema of the lungs suggests that this was not a case of sanocrysin or "tuberculin" shock, but rather one of direct gold poisoning. Other interesting observations on patients undergoing sanocrysin treatment indicate that allergy is reduced, the rate of sedimentation of the erythrocytes is hastened, and a considerable reduction of the hæmoglobin in the blood occurs. Considering how little is yet known about the dosage of sanocrysin and the indications for its exhibition, it would be premature to pass judgment on its efficacy. It is on record that patients undergoing this treatment have died, not merely in spite of it, but because of it. It is also on record that patients have responded with dramatic success; febrile, debilitated and emaciated, they have in a few weeks been restored to practically complete health. Even in the hospitals in which experience has been gained, uncertainty still exists as to the prognosis of any case submitted to this treatment.

WHOLE MILK IN INFANT FEEDING.

WHILE experts argue about percentage feeding and caloric values and this milk and that milk, the general practitioner remains rather bewildered, knowing as he does that the public is rather unimpressed by all the scientific jargon and that infants continue to thrive despite the use of foods which are denounced by the laboratory worker and the children's physician alike as dangerous and monstrous productions. Nevertheless, there is great value in a frank discussion between experts of what appears on the surface to be a relatively simple problem—namely, "Is the modification of cow's milk necessary in infant feeding?"—and this formed the subject at a meeting of the Section for the Study of Disease in Children of the Royal Society of Medicine on Friday, April 24th. Dr. Leonard Findlay made a strong case for the use of whole cow's milk, although he admitted that even he believed in the modification brought about by boiling, which he considers essential in view of the impossibility of our ever obtaining an absolutely pure milk-supply. He discussed in the first place the differences between breast-milk and cow's milk, pointing out that each of the constituents had been singled out in turn as presenting sufficient divergences to warrant modification. The problem appeared to him to be much more subtle than the mere question of the relative differences of protein, for example, in the two milks, for the real difficulty here probably lay in the essential amino-acids rather than in the particular form in which they are presented in the two milks, and any dilution of cow's milk opened up the danger that certain amino-acids might be so reduced in quantity as to give rise to disturbances in growth, just as the dilution frequently practised so reduced the iron intake of an infant as to produce anæmia. The available proof that an infant is unable to digest whole milk is to Dr. Findlay not convincing, and on the other hand, certain metabolism experiments on marasmic infants had shown that these babies had no difficulty in dealing with cow's milk. His clinical experience had gone to show that a vast majority of children digest and thrive on whole cow's milk, excluding cases where definite infective conditions of the digestive tract were present. Dr. Findlay, in short, considers that the differences between cow's milk and human milk present such a fundamental and subtle problem that the attempt to "humanise" cow's milk cannot possibly succeed, and that boiled whole milk gives better results than any modifications in all except the very youngest infants. Dr. Hugh Thursfield supported the use of boiled whole milk, stating that on purely clinical grounds it had proved to be the best substitute for breast-feeding in the healthy infant.

The case for the modification of cow's milk was presented by Dr. Eric Pritchard and Dr. R. C. Jewesbury. They brought forward the argument that breast-milk is the best food for infants and that any substitute should approximate as closely as possible in composition to breast-milk. Hence, best results were to be expected and were obtained at their hands by modifying cow's milk so as to make it as similar as possible to human milk. Dr. Pritchard pointed out that the problem is not the simple one of dealing with the protein, fat, and carbohydrate so as to obtain these three elements in correct proportion, but the much more complicated one of adjusting the relative proportions of all the 30 different elements of milk, each of which plays some part in metabolism. He pleaded for some biochemical Darwin to correlate all the vast amount of investigation carried out in this field. The problem had not been solved by the simple dilution of milk, any more than it had been solved by giving undiluted milk. The excess protein contained in cow's milk was, in his opinion, dangerous both for its immediate effects in leading to fermentation and the absorption of the toxic products of this process, and also for its remote effects, such as those produced in the liver and kidneys by the extra burden thrown on them and those taking place in that "long-suffering organ, the stomach" by the excessive acid production necessary for the digestion of cow's milk. Dr. Jewesbury also drew a gloomy picture of the results of high protein feeding, describing the clinical signs of restlessness, sleeplessness, constipation, colic, and flatulence, which he believes are all caused by too much protein, and he adduced the excellent results obtained by the simple modification of cow's milk along the lines introduced by Sir F. Truby King. Dr. H. C. Cameron uttered a warning against the taking of a rapid increase in weight as a proof of the success of one or other method of infant-feeding. He looks upon most artificial feeding as in the nature of "sighting shots," and the object of the physician should be to discover the best sighting shot. The general conclusions which arise from this discussion appear to be that for the healthy infant boiled whole cow's milk is as successful as any other food and that for the wasting baby different schools still believe that their methods are the only successful ones. The wide differences of opinion which appear to exist, however, are more likely to be modified by discussions of this nature, and perhaps the public may one day get a unanimous answer to its ever-persistent inquiry, "How are we to feed our babies if we can't breast-feed them?"

THE DIAGNOSIS OF HYDATID DISEASE.

IT is in Australia where hydatid disease is comparatively common that investigations of the serological reactions occurring in this disease can be carried out over a sufficiently large number of cases to make the results of great value. At the Australian Medical Congress of the British Medical Association held in Melbourne in November, 1923, Mr. Horace R. Dew and Miss F. Williams contributed a valuable paper on this subject, now republished in the Transactions of the Congress.[1] They report the results of three years' work on the immunity reactions occurring in hydatid disease. The three tests which have been carried out are the complement-fixation test, the precipitin test, and the intradermal test of Casoni. In the complement-fixation test the antigen used is fresh hydatid fluid and the test appears to be absolutely specific, giving a positive reaction in 80 per cent. of all cases of hydatid disease. Certain cases with thick-walled cysts, barren of scolices, and dead cysts which have undergone fibrosis or calcification fail to give a positive complement-fixation reaction, and in certain other cases some failure of the immunising mechanism is also thought to be a factor in the failure of the test. Hydatid disease in children, in which daughter cyst formation appears to be uncommon, and similarly hydatid disease of the lung, where daughter cysts are frequently absent, also give a negative result. An attempt is being made to obtain antigens of greater sensitiveness for these cases, and the merits of an alcoholic extract of scolices from hydatid cysts of the sheep and of a saline solution extract of scolices which have been digested with trypsin are being investigated. The precipitin test is carried out with fresh hydatid fluid from the sheep and unheated serum from the patient; it runs parallel with the complement-fixation test, is equally specific, and is influenced by the same factors. In its present form, however, it is not so delicate, nor is it quantitative in the same way as the complement-fixation reaction. The "intradermal test of Casoni" consists of the injection into the skin of 0·4 c.cm. of hydatid fluid obtained from the sheep and filtered through Berkefeld filters. The commonest positive reaction consists of the appearance of a wheal at the site of injection within about 20 minutes. Within 12 hours an area of erythema and swelling appears around this which spreads until a large area is involved. This is itchy but not painful, persists for 48 hours, and the wheal disappears with its appearance. There is no general reaction. There are certain variations of this; for example, the whole reaction may be over in a few hours, or there may be a long gap between the appearance of the wheal and the occurrence of the erythema. The test is absolutely specific, but needs careful interpretation and control. This test appears to be of particular value in the detection of uncomplicated cases of hydatid disease before operation. The immunological phenomena occurring in this disease are of great interest, and the combination of these three tests will, according to this recent work, enable at least 90 per cent. of cases of hydatid disease to be diagnosed.

DETERMINATION OF FALLOPIAN PATENCY.

Transuterine insufflation of oxygen or carbon dioxide gas combined with roentgenography is the ingenious method devised by Rubin, in 1919, to test the anatomical patency of the Fallopian tubes. Since that date the procedure has been extensively adopted in America with apparent success, but does not appear to have received the same support in this country, although Mr. Victor Bonney recently described in our own columns [1] a simple form of inflation apparatus and what may be learned by its use. In normal cases a measured quantity of gas is introduced into the peritoneal cavity, an artificial pneumo-peritoneum establishing definitely the patency of one or both tubes. In a recent paper,[2] based on an analysis of 1000 consecutive cases, Rubin concludes that the most advantageous time to perform the test is the fourth to seventh day after the completion of the last regular menstrual period. As is well known from the work of Hitschmann and Adler, the endometrium at this stage of the menstrual cycle has shrunk to its minimum thickness and is relatively quiet; the glands have collapsed and ceased to secrete. Theoretically, therefore, during the post-menstrual interval there should be less mechanical resistance to the passage of the gas, and Rubin has found by actual manometric readings that this is so. The risk of endometrial dislocation, air embolism, and the carrying of infection should be reduced to a minimum; neither should there be any chance of disturbing an early and unrecognised pregnancy. The method is considered to be free from danger in properly selected cases, but clinical and experimental observations have pointed to the advisability, in any event, of not exceeding a pressure of from 200 to 250 mm. of mercury. Higher pressures have been employed by experienced hands in the attempt to open tubes that have been previously demonstrated to be stenosed or closed.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.

The report for the year 1924 will be presented at the annual general meeting of the Society on May 6th. Since the last report 17 new members have been elected and 9 have died. The Society at the present time consists of 1 honorary, 156 life, and 141 ordinary members. The invested capital now stands at £148,650; in conformity with the by-laws only income may be used for the payment of grants and expenses. The income from investments amounted to £4786, £350 were received from subscriptions and donations, £68 from life subscriptions, and £600 from legacies. The working expenses were £360. During the year 5 widows died and 4 came on the funds; on Dec. 31st there were 51 widows and 7 orphans in receipt of grants. The grants to orphans on the Brickwell Fund were increased by £10 per annum, making the annual grant to each orphan from this source £25. The Christmas present to the widows was also increased, those over 75 years of age receiving £20 each and those under 75 £15 each; in previous years the Christmas present to the widows had been one of £10 each. One of the widows who had died had been on the funds since 1847; her late husband paid in subscriptions £37 16*s.* and his widow received in grants £3250; another whose husband had paid £12 12*s.* received in grants £1885. The Society, which was founded in 1788 and incorporated by Royal Charter in 1864, is open to any registered medical practitioner who at the time of his election is resident within a 20-mile radius of Charing Cross. Relief is granted to the necessitous widows and orphans of deceased members of three years' standing and of life members. The annual subscription for a member who at the time of his election is under 40 years of age, is 2 guineas, if over 40 but under 50, 3 guineas, and if over 50, 4 guineas.

TOBACCO AMBLYOPIA.

It must often have occurred to those in charge of ophthalmic clinics to wonder why some patients fall victims to the toxic effects of nicotine so much more readily than others. It is not so very uncommon to find patients undoubtedly suffering from toxic amblyopia who tell you that they smoke no more than two ounces of shag a week, while others can stand far greater quantities up to an advanced age without any obvious ill-effects on the sight. Though the symptoms of tobacco amblyopia are characteristic—especially the paracentral scotoma—it is perhaps comparatively seldom that tobacco alone is responsible. Of other contributing factors the influence of alcohol is not likely to be overlooked. That of gastro-intestinal sepsis and of diabetes must also be borne in mind. Another possible factor is emphasised by Prof. G. E. de Schweinitz in a paper recently read before the Section of Ophthalmology at the College of Physicians of Philadelphia[1]—viz., senile changes in the optic nerve which may themselves be capable of causing a certain degree of optic atrophy, not necessarily progressive. These senile changes may depend on alteration of the small blood-vessels within the optic nerve itself; they may, on the other hand, be caused by the pressure of an arterio-sclerotic carotid artery or ophthalmic artery on the nerve; or, again, they may be due to changes in the nerve itself recently described by G. Fuchs, who found amyloid bodies developing from the neuroglia which were damaging and displacing the nerve bundles. These considerations may serve to explain the apparent difference in the capacity of different patients to resist the poison of nicotine, and also the fact that while abstinence from tobacco in most cases is followed by complete restoration of vision, in others the cure is at best but partial.

THE LATE PROFESSOR O'SULLIVAN.

SHORTLY after the death, last year, of Dr. A. C. O'Sullivan, professor of pathology in the University of Dublin, a committee was formed to collect funds in order to perpetuate the memory of his connexion with Trinity College and especially with the School of Pathology, of which he was for nearly 30 years the head. Over £1000 has been collected and with this sum a scholarship has been founded in the School of Physic. The O'Sullivan scholarship, valued at about £48 a year, is to be awarded, on the nomination of the School of Physic Committee without examination, to the most deserving candidate, consideration being given to his record in the medical school, in the University generally, and also to his financial circumstances. In addition to the foundation of the scholarship a bronze tablet has been erected in the School of Pathology which bears the following inscription :—

Alexandro Carlo O'Sullivan
Huius Collegii Socio
Qui in Hac Schola Scientiae Pathologicae Cathedram
Primus Obtinuit
Viro Magnanimo Omniumque Artium Capacissimo
Lugens Universitas
Hoc Monumentum Posuit
MCMXXIV.

The tablet was unveiled by the Provost of Trinity College on April 21st, when Dr. W. G. Smith, emeritus professor of materia medica, on behalf of the subscribers, presented the scholarship and tablet to the College.

SIR JOHN MACALISTER.

WE announced last week the resignation of Sir John MacAlister from the post of Secretary to the Royal Society of Medicine, which he has held since the foundation of that Society by the amalgamation of its constituent bodies. At the meeting of the Council of the Society last week the following resolutions were proposed from the chair by the President, Sir StClair Thomson, who said that no formal resolutions could be too generous in making public acknowledgment of the affection felt towards MacAlister, and the regret which all had experienced on realising that his state of health compelled his resignation. The following are the resolutions submitted :—

1. That the Council of the Royal Society of Medicine desires to express its profound regret that ill-health has compelled Sir John MacAlister to resign his office of Secretary, which he has held since the year 1887. In accepting his resignation the members fully realise that the Society as at present constituted owes its creation to his organising powers ; that its growth and success are chiefly due to his zealous devotion to his duties ; and that its welfare and reputation have been his life's work.

2. That the Council unanimously offers its most sincere thanks to Sir John MacAlister for his 38 years of ungrudging and loyal service to the Society.

3. That the Council sends its affectionate good wishes for Sir John MacAlister's restoration to health and vigour.

4. That the Council has great pleasure in inviting the Society to elect Sir John MacAlister as an Honorary Fellow of the Society.

Sir StClair Thomson went on to recall MacAlister's three great achievements in connexion with the Society. The first, he said, was the move of the old Medico-Chirurgical Society from Berners-street to a building in Hanover-square, large enough to house it, to lodge its increasing library, and to supply meeting rooms to many kindred societies. The second was the federation of these 18 societies into the Royal Society of Medicine, the largest society of its kind in the kingdom, and with the most complete medical library in the Empire. The third great feat was the erection of the Society's house in Wimpole-street, the move there and the consolidation of success. The words of Sir StClair Thomson and the resolutions referring to the work of MacAlister were immediately endorsed by two previous Presidents of the Society, Sir Humphry Rolleston and Sir William Hale-White, and THE LANCET desires to be associated with this tribute to MacAlister's staunch and devoted service to the medical profession. We are informed that Sir John MacAlister feels that he has no longer the vigour necessary to the adequate performance of his duties, but his resignation does not take effect till the end of June, and we hope that, when it has taken place, he will long continue to enjoy his leisure ; we are certain that his old friends will frequently see him among them. During MacAlister's absence much of the administrative work has been admirably carried on by the hon. secretary, Mr. W. Girling Ball, whose assistance was warmly acknowledged by the President.

THE BUDGET.

Mr. Churchill's first Budget is both personally and professionally interesting to the medical man. Sixpence off the income-tax will afford welcome relief to practitioners whose income is so largely earned by personal exertion, and the increase in the allowance on earned income from one-tenth to one-sixth will be of special benefit to the increasing number of medical men and women receiving fixed salaries from local authorities. Professional interest centres around the proposals for old age and widows' pensions. It has long been foreseen by medical statisticians, and pointed out more than once by Dr. J. Brownlee in our own columns, that the number of old people in 30 years' time will be vastly greater, possibly twice as great, in proportion to the working population than it is at present. No one but the medical man in an industrial area knows so well what the anxiety of failing means in old age and of the resulting economic pressure on the family circle may mean to the health of the community. Mr. Churchill's proposal will ultimately provide a pension at the age of 65 years for everyone coming at present within the scope of the National Insurance Acts, and will abolish the present restrictions and tests on pensioners at the age of 70. The cost is to be met by a weekly contribution of fourpence a man and twopence a woman in addition to the present rate of health insurance contribution, with further additions after the tenth year, ultimately increasing the man's weekly contribution to sevenpence. At the end of 80 years the Chancellor calculates this scheme will have become entirely self-supporting without any contribution from the State, which in the meantime can recoup itself out of the steadily diminishing cost of war pensions. Pensions of 10s. a week for widows of all men under National Health Insurance will come into force at the beginning of next year, with additional sums for children under the age of 14. The whole scheme is a useful instalment of social insurance which should make for national health.

THE first Lister Memorial Lecture of the Royal College of Surgeons of England will be delivered on Thursday, May 14th, at 5 P.M., by Sir William Watson Cheyne.

INCORPORATED ASSOCIATION OF HOSPITAL OFFICERS. The annual Congress is to be held at St. Thomas's Hospital, London, on Friday, May 15th, when an address of welcome will be given by Sir Arthur Stanley at 10 A.M. The Congress opens with an address by the President, Mr. W. H. Harper, at 10.15, and at 10.30 Dr. F. N. K. Menzies will read a paper on the Rôle of the Auxiliary Hospital or Home of Recovery in the Voluntary Hospital Organisation, Mr. E. W. Morris and others taking part in the discussion. At 2 P.M. Mr. A. G. E. Sanctuary will open a discussion on the Effect of Hospital Savings and Contributory Schemes on Voluntary Contributions, Dr. H. L. Eason being in the chair. At 4 P.M. there will be an official reception at the House of Commons. The annual dinner will be held at the Holborn Restaurant in the evening, and visits to London hospitals are being arranged on the following day. Inquiries may be addressed to Mr. J. E. Stone, Hon. Secretary, 28, Bedford-square, London, W.C. 1.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CXX.—THE TREATMENT OF EXCESSIVE LOSS AT THE PERIODS.

I. WHEN THE UTERUS IS ENLARGED BUT NO FIBROIDS ARE PRESENT.*

General Considerations.

MENORRHAGIA means excessive loss at the menstrual periods, but its occurrence is often not *monthly* because the happenings in the ovary which determine the menstrual flow may occur at shorter or longer intervals than that. As a rule these happenings take place regularly, so that the menstrual flow is regular though perhaps not monthly, but sometimes the ovary itself is "irregular," so that the menstrual flow is irregular too. The term metrorrhagia signifies loss occurring between the menstrual periods and unconnected with those ovarian changes which are the basis of menstruation, and it is therefore necessary to distinguish this form of irregular bleeding from a menorrhagia which, though irregular, depends for its initiation on changes in the ovary. Metrorrhagia is quite independent of such changes, and indeed can, and sometimes does, occur in a woman who has no ovaries. This article deals with menorrhagia only.

Normal menstrual loss passes into menorrhagia so soon as the woman begins to lose more blood than she can afford. In this regard there are great individual differences. Some persons throughout their lives lose each month an amount of blood considerably in excess of the normal and yet without ill-effect, their blood-forming apparatus presumably being equal to the demand. In determining whether a woman has menorrhagia this fact must be taken into account and inquiry made as to the amount she has been accustomed to lose since her menstrual life began. The amount lost is also relative to the patient's physique. A big woman can, other things being equal, afford to lose more than a small woman. It is usual to gauge the blood loss by the number of diapers used during the whole period; thus eight signifies scantiness, 12 somewhere about normal, 16 distinctly too much, 20 undoubtedly excessive, and 30 or 40 "flooding." The rapidity with which the blood is lost must also be taken into account. A woman who uses 12 diapers during a period lasting three days loses much faster than one who uses the same number during a period lasting a week. In some cases, again, a large proportion of the total number are used within the first 24 or 48 hours, so that the loss whilst at its maximum rate is excessive, though the total amount lost is not so. A woman who uses eight diapers in one day is losing too much, even though she only uses 12 over her whole period of five days. The loss may be excessive by too long continuance as well as by too rapid flow, and in the severe cases both abnormalities are coexistent.

The diagnosis of menorrhagia in any given case rests finally on a general survey of the patient herself. If she is losing too much she will be anæmic, at first only immediately during and after the period, but later on continuously. A woman anæmic from whatever cause is obviously unfit to lose any blood at all until her blood content is restored; to her even a normal period is "menorrhagia." Considerations of this sort frequently arise, notably in cases where it has to be decided whether to stop the periods altogether by hysterectomy or adopt some other course, operative or medicinal, with the view of making the loss "normal" again. Where a patient is very exsanguine, as, for instance, in some cases of fibroids, the periods of themselves often diminish in profuseness, and unless the medical attendant takes these facts into consideration he may mistakenly suppose his patient to be improving; whereas relative to her extreme anæmia the monthly loss is just as harmfully excessive as ever it was. Any improvement of the blood content of these patients by medicinal means at once causes the loss to increase again.

When it is determined that the patient is really losing too much, the next step is to seek the cause by physical examination. As far as the uterus is concerned, broadly speaking, one of three conditions will be found: either it will be (1) abnormally large, (2) normal in size, or (3) abnormally small.

Menorrhagia with an Enlarged Uterus.

A large uterus, other things being equal, will bleed more than a small one because the menstrual area is bigger. Sheer enlargement then without any structural disease will cause the loss to be excessive. The size of the uterus varies a little in normal virgin women, but not to any great extent, though I have seen a few cases where the oversize was so marked as to suggest a developmental abnormality, the reverse of the undersized uterus much more commonly met with.

Subinvolution.—The commonest cause of simple enlargement unaccompanied by gross structural disease is subinvolution, and in its lesser degree it is present in many parous women whose wombs remain permanently bigger and whose periods remain slightly but definitely freer than they were before the women conceived. When the failure to return to the normal size is marked, menorrhagia usually accompanies it. The subinvoluted uterus for at least six months after the pregnancy is capable, I think, of being reduced in size by suitable treatment, but after this period the enlargement becomes increasingly established, until eventually certain intimate structural changes take place in its substance which result in one form of the condition known as "fibrosis." The term, however, is ill applied to this class of case, for the primary change is in the nature of a hyaline degeneration of the muscle-fibres to which the apparent overgrowth of white fibres at a much later stage is secondary. A uterus in this condition usually bleeds profusely, and also often presents other abnormalities—e.g., retroversion, cervical laceration, chronic cervicitis, and erosion.

In the treatment of these cases the first point to bear in mind is that for, say, six months after labour there is certainly a fair chance that suitable treatment may cause involution to take place, but after this period the likelihood of the big uterus shrinking becomes less and less. Ergot is the first drug to try and should be given in full doses (ʒi.) t.d.s. from a few days before the period is due until the flow is over. If the loss is very great pituitrin can be given hypodermically once or twice a day. If these fail other uterine styptics are not likely to succeed, but they can be tried. Many of these cases present retroversion as well, and it is important to rectify this, not only because reposition at this period may permanently cure the displacement, but because retroversion delays or prevents involution. Drugs failing, the uterus should be curetted. The results obtained from this operation are best when its application is not too long delayed. If retroversion is present this should be corrected at the same time by manual or instrumental reposition and the temporary introduction of a pessary. Such treatment, if carried out within the first six months, often cures the patient. The pessary, however, should not be worn for more than six months; if at the expiry of this period the uterus retroverts when it is left out the instrument should be abandoned and the patient advised to have the displacement permanently corrected by operative means.

When subinvolution has existed for a long time the chances of curettage benefiting the menorrhagia are much diminished, because the uterine wall has undergone permanent change. In such a case when, after the usual drugs have been tried and failed, curettage is in contemplation the surgeon will be well advised if he tells the patient beforehand that the operation may fail in its intent, adding, however, that it is advisable because there is nothing between it and more drastic measures. If retroversion is present this should be dealt with at the same time by intraperitoneal shortening of the round ligaments and coexistent cervicitis should be met by excision of the inflamed surface and repair, the aim of the surgeon being to leave the parts in as normal a condition as possible in the hope that the degenerative processes in the uterine wall may stop or regress.

---

* An article on the Treatment of Excessive Loss at the Periods, when the uterus has fibroids, is normal in size or small, will appear next week.

There are times when the hæmorrhage is so severe that it becomes urgent to relieve it with certainty. In women over 40 years of age hysterectomy is the simplest solution of the problem, but the difficult cases are those in which the patient is relatively young, and removal of the uterus is to be avoided if possible. In such, as an alternative, I have employed abdominal hysterotomy. The abdomen being opened the uterus is incised through its anterior wall until its cavity is opened and the endometrium is then scraped far more thoroughly than can ever be done from below. The handle of the scalpel is a most efficient scraper. Such thorough curetting is often followed by several months amenorrhœa, and in my hands it has proved a successful operation. There is this advantage in opening the cavity of the uterus—namely, that more frequently than would be thought some intra-uterine condition, like a small fibroid or mucous polyp, is discovered, which is the real cause of the bleeding, although its presence was not detectable by other means. When the uterus is considerably enlarged it may be reduced in size by cutting part of it away (utriculoplasty).[1] When doing this operation I used to excise a wedge-shaped portion, cutting through both front and back walls, but I now excise the front wall only so as to keep the suture line on the anterior surface.

There is a further class of case in which it is undesirable to remove the uterus because of the likelihood of making worse an already existent prolapse of the vaginal vault. In such cases I excise the entire corporeal endometrium and suture the rest of the corpus so as to make it into a solid column of muscle tissue. This column is then ventrofixed so as to act as a ligament to keep up the weak vault. This is a good operation.

There are two other ways of dealing with hæmorrhage from a *chronically subinvoluted uterus*—radium and X rays. Radium acts by destroying less or more of the endometrium, and is, in fact, equivalent to curettage, except that it produces more fibrosis. If the destruction is limited to the superficial layers the periods may be lessened in amount, or even temporarily suppressed for several months, as after hysterotomy and curettage. If the destruction is complete permanent amenorrhœa is effected. Totally to destroy the endometrium a considerable exposure is required, but on account of its varying thickness it is impossible accurately to gauge the exposure required to do this, and, moreover, there is a degree of danger in procuring an effect so drastic. Where the uterus is definitely enlarged I hold that radium is not the treatment of choice, and still less so if, in addition, displacement or chronic cervicitis and erosion are coexistent. With a normal sized uterus, or one smaller than normal, the indications for its use are stronger.

X ray treatment in these cases is as much to be condemned as it is in cases of fibroids, under which heading I will refer to it more particularly.

Special Articles.

NOTES ON SOME PHYSIOLOGICAL PROBLEMS OF MOUNT EVEREST.

By Leonard Hill, M.B. Lond., F.R.S.,
and
Argyll Campbell, M.D., D.Sc. Edin.
(From the National Institute for Medical Research, Hampstead, N.W.)

I. Glacier Lassitude.

In dealing with the physiological difficulties of the Mount Everest Expedition, 1924, Major Hingston,[1] the medical officer, drew attention to what he termed glacier lassitude. To quote his own words :—

> "A distinct feature in the Mount Everest region is the very pronounced glacier lassitude which develops over tracts of ice. This was most marked on the Rongbuk glacier, especially when passing through a trough in the ice at an altitude of 20,000 feet. The trough was a remarkable feature, being girt on either side with walls of ice in many places hewn into fantastic pinnacles and ornamented with pyramidal spires. In this trough there was a peculiar sapping of energy, a weakness of the legs, and a disinclination to move. It was not a breathlessness due to exertion, but to a loss of muscular power. There was a feeling of prostration. One seemed to drag oneself along, instead of going with the usual strength. A profuse sweating was not uncommon. It was something like the oppression experienced when marching through a hot moist jungle in the rains. The lassitude appeared immediately after stepping on to the glacier; it was as quickly relieved on again reaching rock or moraine. It was most noticeable in the absence of wind and in the middle of the day when the sun was strong. It was absent late at evening and in the early morning, and was less marked on cloudy days.
>
> "The cause of this lassitude is easily explained. The conditions for its development are a sheet of ice, a hot sun, and a still air. The sun melts the superficial layer of the ice. The lowest stratum of the atmosphere becomes saturated with moisture but does not rise owing to its being chilled by contact with the ice. Thus, when on the glacier, one is in a saturated atmosphere, and this, in conjunction with the high altitude, is sufficient to cause the unpleasant effects.
>
> "We did not notice that other atmospheric conditions had any special influence on these high altitude symptoms. This was different from my experiences in the Western Himalaya. There, on two occasions, our party climbed the same peak to a height of 18,203 feet. During the first ascent the sky was clear, the air was free from moisture, and our disability was slight. On the second occasion the conditions were different. The sky was dark, stormy weather was imminent, and the atmosphere felt heavy and damp. Our distress on this second occasion was acute. Every few paces found us gasping for breath, and we had repeatedly to make short halts. The same explanation applies to this as in the case of the glacier lassitude. On the second ascent the atmosphere was laden with moisture. The free evaporation of perspiration was checked and, as a consequence, the high altitude symptoms were increased."

Major Hingston thus clearly demonstrates that great lassitude was produced by overheating the body whilst at a high altitude, whereas the altitude alone caused no such symptoms. He does not give any physiological explanation of this prostration. We know already that ordinary discomfort due to overheating is accompanied by an increase in pulse-rate; in fact, it is generally agreed that the pulse-rate is the best indicator of discomfort due to overheating. Major Hingston does not give the pulse-rate of his subjects whilst suffering from glacier lassitude. Altitude itself, as is well known,[6] increases the pulse-rate at rest, and markedly increases the pulse-rate whilst at muscular work. Here again pulse-rate is considered to be a good indicator of distress.

We consider that most likely the combined effects of overheating and altitude caused the prostration by fatigue of the heart, the heart having to pump blood to the skin for cooling as well as to the muscles for work. Since we do not know of any previous experiments dealing with such a combination we record below some experiments which demonstrate that the combined effects of these two conditions markedly increase the heart beat. Previous observers have obtained some evidence that heart output is increased by overheating and by anoxæmia. Uyeno [2] has shown that the pulse-rate and output from the heart are increased by overheating. Haldane,[3] in reviewing the effects of anoxæmia upon the circulation, states that there is an increase of pulse-rate and of heart output. There is, however, some evidence[4] that heart output is not increased at rest by anoxæmia, although the pulse-rate is definitely increased.

Symptoms.—19/11: Weak; giddy; lips dark blue. 2/12: Headache. 3/12: Weak; giddy; lips dark blue. 4/12: Weak; giddy. 5/12: Weak; giddy; shivering. 9/12 and 10/12: Nil. 11/12: Weak; giddy; lips dark blue.

* Figures in parentheses give the pulse pressure. S, systolic; D, diastolic.

† The pulse-rates were lower in the second period of work (98) than in the first period (107) because the subject was cooler during the second period, having been exposed longer to the cold wind. The same effect is shown in Exp. II.

Plan of Experiment.

We employed two subjects, C. P. and D. S., who had acted as subjects in similar experiments on several previous occasions. They were not acclimatised to breathing oxygen at low tensions. C. P. was a healthy active individual but not of athletic habit. D. S. was of athletic habit and kept himself in training for football. D. S. wore ordinary winter clothing—that is, he was warmly clad—whilst C. P. wore light summer garments and worked in his shirt-sleeves and collarless. They worked on Schuster's[5] modification of the bicycle ergometer, doing only light work—namely, 300 kilogrammetres per minute at about 70 revolutions per minute, the pace being controlled by metronome. D. S. worked only for ten minutes, whilst C. P. worked for two periods of ten minutes separated by an interval of rest of about 12 minutes' duration; this was sufficient to give evidence—e.g., weakness (faintness), giddiness, headache—of oxygen deficiency under our conditions. All the experiments were carried out about three hours after breakfast.

To imitate the atmosphere at an altitude of 20,000 feet we used mixtures of gas containing about 10–13 per cent. of oxygen—that is, about half the oxygen content of the normal atmosphere at sea level, namely, 20·9 per cent. The gas was placed in a large balloon capable of holding 3000 litres, and the subject breathed the gas through an ordinary mouthpiece fitted with Rosling valves. The mouthpiece was used also when breathing normal air, to keep the experimental conditions constant. Some experiments were carried out in a laboratory room which was heated up to about 20° C.—that is, not very warm. Others were carried out in a tunnel at about 8–10° C., but as the tunnel was fitted with a large fan fairly cold conditions were obtained, giving high cooling powers as measured by the kata-thermometer.

Systolic and diastolic blood pressures were estimated by the auscultation method (brachial artery) just before commencing work and immediately after cessation of work. At intervals during work the pulse-rate was counted in the radial artery at the wrist, counts by two different observers agreeing closely; none of the figures exceeded 150 per minute.

The main results of the experiments are given in tables; full details for subject C. P. will be found in Table I. As the details for D. S. were similar they are omitted. Some experiments were carried out in which the subjects walked for ten minutes on a revolving platform at the rate of four to five miles an hour. The results obtained were similar to those given for the ergometer and are therefore omitted.

Increase of Pulse-Rate under Warm Conditions.

The main results of these experiments are given in Table II. We compared two sets of atmospheric conditions keeping other experimental conditions similar; one set of experiments was carried out in a moderately warm room about 20° C. dry bulb, and with a dry kata-thermometer cooling power of about 5 millicalories per sq. cm. per sec.; the other set of experiments was carried out in a tunnel with a strong wind blowing, the dry-bulb temperature being about 8–10° C., whilst the dry kata-thermometer cooling power was about 32.

In Table II. the experiments are numbered mainly for reference to the detailed accounts in Table I. In Tables II., III., and IV. the experiments which are compared with one another are bracketed together. It will be observed that with subject D. S. (Table II.) the pulse-rate was on an average 12 beats per minute faster under the warmer conditions (dry kata cooling power 5·0) than under the cool conditions (cooling power 32·0). C. P.'s pulse-rate was very much faster under the warmer conditions (cooling power 5·0), being on an average 24 beats per minute faster than under the cooler conditions (cooling power 32·0). C. P., as already stated, was only lightly clothed and remained longer in the cold wind than D. S., and was therefore much more cooled down by the wind than D. S. It will be observed that these differences were similar, whether the subject was breathing oxygen at a high percentage, i.e., 20·9, or at low percentage, i.e., 10–13. Under the low oxygen tensions due allowance was made for the effect of temperature upon the oxygen content of a given volume of gas; of course, the quantity of oxygen present in a given volume of gas at 0° C. is nearly 0·8 per cent. higher than in the same volume of gas at 20° C., owing to expansion under increase of temperature.

* Increase in pulse-rate due to *A*, warmer conditions; *B*, low oxygen; and *C*, low oxygen plus warmer conditions.

Increase of Pulse-Rate due to Breathing Air with Low Oxygen Tension.

These experiments are given in Table III. Here the atmospheric conditions were kept constant whilst the oxygen percentage was varied from about 10 to 21. It will be observed that with subject D. S. the pulse-rate was on an average 14 beats faster whilst at work and breathing oxygen at low tension. Some experiments were done under warm conditions, i.e., cooling power 5·0, and some under cool conditions, i.e., cooling power 32·0, the effect of the low oxygen tension being much the same in both cases. C. P. gave similar results, his pulse-rate on an average being 11 beats faster per minute whilst breathing oxygen at low tension; his experiment under the warmer conditions, i.e., cooling power 5·0, did not show so great a difference in pulse-rate as those of D. S. under similar conditions because C. P. was more lightly clothed and therefore less heated.

Increase in Pulse-Rate due to the Combined Effects of Warm Conditions and Low Oxygen Tension.

We have shown that in D. S. the pulse-rate was about 12 beats faster under warm conditions, and about 14 beats faster under low oxygen tension, so that, as might be expected, the effect of combining these conditions was that the pulse-rate was about 26 beats faster than whilst breathing normal air under cool conditions. Similarly, for subject C. P. the combined effects of heat and low oxygen tension produced a pulse-rate about 35 (24 + 11) beats faster than the rate under cool conditions with normal oxygen tension. This comparison is made clearer in Table IV. The details of the experiment under the warmer conditions (cooling power 5·0) and with low oxygen tension (10·9–13·6) are in each case given above those for the cooler conditions (cooling power 32·0) and with normal oxygen tension (20·9). C. P. was more affected by breathing air with low oxygen tension than D. S. C. P. was not able to work for any length of time with a lower oxygen tension than 13 per cent. without becoming weak and giddy. C. P. was less in training than D. S. Athletes in training are less affected by altitude than more sedentary individuals.

In both subjects symptoms of anoxæmia and discomfort were more marked under warm conditions with low oxygen tension than under other conditions studied.

Effect of Breathing Air Saturated with Moisture and at Low Oxygen Tension.

Major Hingston refers to the air being saturated with moisture in the case of glacier lassitude. It was considered that breathing air saturated with moisture might, at low oxygen tension, interfere with the passage of oxygen through the lung epithelium into the blood, owing to (*a*) the lowering of oxygen partial pressure by increase of vapour pressure—this factor is almost negligible in itself under the conditions concerned; (*b*) increased wetness of the pulmonary epithelium—e.g., as in œdema. Using the pulse-rate as an indicator, experiments were carried out breathing fairly dry air (relative humidity 50–60 per cent.) and breathing air saturated with moisture (relative humidity 100 per cent.), the oxygen tension being low in both cases. The pulse-rates were much the same, so we concluded that the moisture did not interfere with the absorption of oxygen under our experimental conditions.

The experiments concerned are for D. S., Nos. V. and I., and for C. P., Nos. VIII. and I. In the first-mentioned experiment for each subject the air in the balloon was saturated with moisture (T. = 20° C.). In the second experiment the air was much dryer (dry bulb = 20° C.; wet bulb = 12° C.).

Blood Pressure.

Schneider and his colleagues[6] have studied the problem in detail and have shown that light muscular work at high altitude causes but a slight increase in systolic blood pressure, but more severe work markedly raises the blood pressure. An examination of our figures for blood pressure given in Table I. will show that breathing air with low oxygen tension during light work did not produce any immediate after-effects on blood pressure which differed materially from those obtained when air with normal oxygen tension was breathed, although the former conditions produced cyanosis and giddiness. It was observed that the pulse pressure—i.e., the difference between systolic and diastolic pressures—was greater after work than before; this was not dependent upon the oxygen tension in the air breathed and was previously observed under normal conditions by Dawson.[7]

Conclusion.

From the above results it may be concluded that "glacier lassitude" was due to the combined effects —of over-heating of the body and of breathing oxygen at low tension—upon the heart; and also that under such conditions the pulse-rate is a good indicator of distress of the heart and of body discomfort, a pulse-rate of 140 per minute being observed in our subjects just before failure to complete the task imposed upon them.

II. The Value of Oxygen.

Major Hingston[1] points out that theoretically the breathing of oxygen should have proved of enormous benefit in alleviating the symptoms produced by the high altitude. He states that it is remarkable how little benefit was obtained from the oxygen compared with the experiences of the previous expedition. In the discussion which followed Major Hingston's paper Prof. Haldane stated that in acclimatised individuals it is not mainly want of oxygen which is worrying immediately at onset of muscular work at high altitude, but excess of carbon dioxide which must be kept much lower in order to preserve normal alkalinity, the blood losing alkali at high altitude. Mr. Barcroft pointed out that the climbers may not have been getting the adequate or calculated amount of oxygen, and questioned whether the cumulative effects of want of oxygen over days and weeks can be abolished by the immediate breathing of oxygen. This appears to be of great importance; it is not likely that results obtained by breathing oxygen during anoxæmia at sea-level may be applied to an individual who has become acclimatised to such high altitudes.

Some results indicating the beneficial effects of breathing oxygen at high tension during exercise at sea-level are of interest in the present discussion. L. Hill and Flack[8] showed that an athlete can perform vigorous exercise for a longer period when breathing oxygen at a high tension; they showed that the high oxygen content in the lung enabled an athlete to tolerate a higher CO_2 tension—even up to 11 per cent.—in the alveolar air. They[9] also found that the time taken to run a given distance is lowered, the pulse frequency lowered, and blood pressure kept up by breathing oxygen and a feeling of relief to the dyspnœa is given by the oxygen; they thought that oxygen inhalation increased the lasting power and lessened the fatigue of athletes by maintaining or restoring the vigour of the heart. More recently A. V. Hill and his colleagues[10] have suggested that the heart output during work varies directly as the oxygen saturation of the arterial blood, because they found an increase of oxygen-intake whilst breathing oxygen at 50 per cent., instead of the normal 21 per cent. oxygen, and a decrease of oxygen-intake whilst breathing oxygen at 11·3 per cent. In other words, anoxæmia decreased the output of the heart during work, and increased oxygen saturation of the blood increased the output of the heart. It is difficult to understand how there can be any "unsaturation" of the arterial blood whilst breathing oxygen at 21 per cent. unless the subject is unfit to do the task or the breath is held during it. We know that many believe there is during exercise in untrained individuals some anoxæmia, but we doubt if any observer has proved by direct observation that the arterial blood is at all unsaturated by muscular exercise in fit individuals breathing freely. One of us (J. A. C.) has carried out observations on rabbits which in order to escape being held struggled vigorously for a few minutes until tired. Exercise produced a slight increase in the saturation of the arterial blood whilst the animal was breathing ordinary air with 21 per cent. oxygen. Samples were taken immediately before and immediately after exercise from a large artery of an ear of a suitable rabbit and the oxygen content in 2 c.cm. of blood estimated by Van Slyke's method. The five experiments completed indicated about 15 volumes per cent. in the arterial blood, a normal figure for the rabbit. If, then, exercise does not produce any unsaturation of the blood whilst breathing 21 per cent. oxygen, it is difficult to see how breathing 50 per cent. can make any difference beyond the increase in the quantity of oxygen in solution; this, although small, may quite easily be doubled in amount. Thus, if the alveolar oxygen is at a tension of 90–100 mm. Hg there would be about 0·25 volume per cent. oxygen in solution and the hæmoglobin fully saturated, whereas if the alveolar oxygen tension were increased to 150 mm. Hg the hæmoglobin is, of course, fully saturated, but the dissolved oxygen is now 0·40 volume per cent.—a big increase on 0·25. It is quite possible, then, that it is the oxygen in solution in the blood which is the deciding factor. It is obvious that as far as the cells of the respiratory and other centres, and of the heart and other organs, are concerned, it is the oxygen in solution that first alters their surrounding conditions. We know that the excised heart can be kept beating if the coronary arteries are perfused with oxygenated Ringer's solution, and that a mouse poisoned with carbon monoxide can live in two atmospheres of oxygen, there then being enough in solution to keep it going (Haldane).

Therefore the amount of oxygen in solution in the blood and tissue fluids is probably of more importance at a high altitude than the degree of saturation of the hæmoglobin with oxygen; of course, one depends to a great extent upon the other; but the limiting factor to endurance may be the removal of O_2 from the fluids bothering the tissue cells at a rate more rapid than the passage of O_2 from the blood to these tissue fluids; the latter, of course, depends upon the O_2-tension in the plasma—i.e., the oxygen in solution. It may be that in the Everest climbers the oxygen in solution is below the limit required by the nervous system and heart. Thus if, say, at 29,000 feet, where the pressure is about one-third atmosphere or 250 mm., to gain any advantage at all from oxygen nearly pure oxygen would have to be used. The Everest oxygen apparatus was arranged to deliver up to 5 litres per min., the oxygen flowing through a tube held in the mouth. Supposing the tap was turned so as to give 3 litres, these at one-third atmosphere pressure would expand to 9 litres, and much would be lost to the air. The mouth would be open owing to the deep respirations taken, and the dilution of oxygen with air was then probably great. Breathing air containing, say, 30 per cent. of oxygen at this height would only give about 84 mm. pressure in the air breathed and perhaps only about 60 mm. pressure of oxygen in the alveolar air, which would mean less than 90 per cent. saturation and only 0·18 volume per cent. oxygen in solution. This is shown in Table V., slightly modified—after Van Slyke and Stadie.[11]

Table V.—*Oxygen Estimated Held in Physical Solution by Blood at 38° C. at Different Oxygen Tensions and Saturations.*

A. = Saturation of hæmoglobin in blood with O_2 (per cent.).
B. = O_2 tension (alveolar air) corresponding to saturation in column A. (mm. Hg).
C. = Oxygen physically dissolved at 38° C. (vol. per cent.).

A.	B.	C.	A.	B.	C.	A.	B.	C.
0	0	0·00	50	27	0·08	95	90	0·24
10	11	0·03	60	31	0·09	100	120	0·32
20	16	0·04	70	37	0·11	100	140	0·37
30	19	0·05	80	46	0·13	100	150	0·40
40	22	0·07	*90*	*65*	*0·18*			

Since the alveolar oxygen tension is normally about 90 to 100 mm. Hg there is normally in solution in the blood 0·3 volume per cent. oxygen, and this is the amount immediately available for the tissues, e.g., nervous centres and heart muscle, as the blood flows through them. Perhaps too little attention has been directed formerly to the oxygen in solution in the blood, and it may be the increase in the amount of this whilst breathing oxygen at high tension which is responsible for the increased output of heart, increased intake of oxygen, and general relief to subjects performing excessive muscular work. Also at high altitudes it may be the decrease of the oxygen in solution which is the important factor.

Summary.

(1) In such conditions as "glacier lassitude" as experienced on Mount Everest, produced by the combined effects of overheating the body and of breathing oxygen at low tension during light muscular

work, the heart beat is markedly increased in rate owing merely to summation of the effects of each factor upon the heart. The pulse-rate is an excellent guide to discomfort and distress of the heart during such conditions, a rate of 140 per minute being considered the limit of safety in the subjects under the conditions specified.

(2) The presence of moisture in the air does not interfere with the passage of oxygen through the lung epithelium, although it greatly influences the heart through the overheating of the body owing to reduced evaporation of fluid from the body.

(3) The beneficial effects of breathing oxygen at high tension during exercise are considered to be due to the increased amount of oxygen in physical solution in the blood.

(4) Vigorous exercise in rabbits breathing air at sea-level approximately, slightly increased the saturation of the arterial blood with oxygen.

(5) The amount of oxygen in solution in the blood is probably of more importance than the degree of saturation of the hæmoglobin with oxygen, under conditions of bodily stress.

PROCEEDINGS OF THE ROYAL COMMISSION ON NATIONAL HEALTH INSURANCE.*

(*Continued from p. 891.*)

EVIDENCE OF THE NATIONAL INSURANCE BENEFICENT SOCIETY.

(Q. 8814–8822.) Evidence was given by the joint secretaries, Mr. Canter and Mr. Rockliff, on behalf of this society, which is neither an Approved Society nor a statutory body, but a corporate body acting under licence from the Board of Trade. It has a dual capacity, acting partly as a medium through which various Approved Societies arrange for "additional (treatment) benefits"—mainly dental and optical treatment—and partly as a charity receiving contributions from various institutes and from individual members of trade unions and other bodies by means of collecting boxes.

(Q. 8907–8.) In respect of its unincorporate side, a full account is rendered to each contracting society, but on the incorporate side no such account is rendered,

> because we were legally advised we were not authorised to deal with moneys contributed to a charitable fund in that way. But it is open to [an officer of] any society which is a contributor to our funds to come and ascertain for himself exactly how far its subscriptions to the incorporate body have been spent for the advantage of the persons recommended by the society.

Extent of the Operations of the N.I.B.S.

(Q. 8891–2, 8921–3, 8978.) The total income of the N.I.B.S. for 1923 was about £60,000, equally divided between the two sections of its operations. The society does not act for the large industrial societies, and the total membership of the various societies who make use of its machinery is upwards of 1,000,000.

Arrangements with Dentists.

(App. XVIII., 10–31; Q. 8837.) The number of dentists with whom arrangements have been made by this society were summarised in answer to a question, as follows:—

> Originally in 1921 we entered into contracts with 1500 surgeon dentists. Then we entered into an arrangement with the Incorporated Dental Society, which society included the best of the non-qualified men. Then later on, after the 1921 Act, we entered into arrangements with members of the Public Dental Service Association, which consists very largely of 1921 men. The total number would be 1500 originally qualified men, 1200 Incorporated Dental Society men, and probably 3000 or 4000 Public Dental Service Association men.

The scale of fees first proposed was lower than that arrived at later as a compromise following a dispute with the British Dental Association.

(Q. 8985–8.) Whether because the dentists under the original contract have not appreciated the fact of the later scale, or for some other reason, the fact appears to be that they have not, to a very large extent, gone up to the agreed maximum scale, with the result that the better qualified men are getting the lower fee. This was described by a member of the Commission as a sort of Alice-in-Wonderland scheme. Actual particulars of the scale were not given.

Cost of a National Scheme.

The witnesses were of opinion that a 100 per cent. service would cost approximately 6*s.* 6*d.* per head per annum, but they considered it questionable whether a capitation system of payment could be arranged.

> (Q. 8828.) The capitation fee for medical service is based solely on the service of the medical man himself; but, as regards dental benefit, you have got the mechanic who is involved, you have got the provision of materials for the making-up of goods, quite apart from the services of the dentist himself, and those various factors, in our judgment, would make it difficult to arrange a capitation service with the profession.

The N.I.B.S. has issued approximately 35,000 dental letters. Many thousands of these have not progressed beyond the estimate stage. The experience of one society showed that where a grant of 50 per cent. was reduced to one of 25 per cent., the percentage of uncompleted cases rose from 24 per cent. to 57 per cent.

> (App. XVIII., 16.) It is fair to assume therefore that in any national (or other) scheme of dental benefit not based on a full grant, the number of applicants who would be deprived of the benefit for financial reasons would be somewhere about 50 per cent.

Advocacy of Dental Clinics.

(App. XVIII., 22–24.) This society recommends the setting up of clinics in industrial areas, manned by whole-time dentists, both in the interests of efficiency and cost, but—

> unless clinics were of an attractive character and care were taken as regards the staffing and the manner in which treatment was given, clinics would soon come to be regarded as Poor-law Institutions and fail of their purpose.

The N.I.B.S. has provided a dental clinic (Q. 9006) Attached to it are two dental surgeons, an anæsthetist, and a nurse. One of the advantages claimed is that no unnecessary work or needless extraction is performed.

---

* In previous articles the proceedings of the Commission were reported under the following headings: Introductory Note; The Scope of the Insurance Scheme (see THE LANCET, Jan. 31st, pp. 247–8); The Provision of Medical Benefit (Feb. 7th, pp. 301–3; Feb. 14th, pp. 355–6; Feb. 21st, pp. 403–5); Financial Provisions of the Act (Feb. 28th, pp. 454–7); Medical Certification and the Regional Medical Staff (March 7th, pp. 508–9); The Approved Societies and the Money Benefits (March 14th, pp. 564–5; March 21st, pp. 623–4); Evidence of the Hearts of Oak Society (March 28th, pp. 677–9); Evidence of the National Conference of Industrial Assurance Approved Societies and of the Manchester Unity Approved Society (April 4th, pp. 731–3); Evidence of Independent Order of Rechabites, of Rational Association Friendly Society, and of Miners' Societies (April 11th, pp. 784–6; April 18th, p. 839); Evidence of Mr. Alban Gordon (April 18th, pp. 839–40); Evidence of Joint Committee of Approved Societies, of Stock Exchange and Lloyds' Health Insurance Societies, and of Group of Catholic Approved Societies (April 25th, pp. 889–91).

References to the paragraphs in the printed statements issued as appendices to the reports of the oral evidence are given thus: "App. X. 69," and references to the oral evidence thus—Q. 1369.

A Proposed Machiavellian Scheme.

(App. XVIII., 25. Q. 9041.) The witnesses suggested what was described by a member of the Commission as a rather Machiavellian scheme as likely to be advocated by the dental profession—namely, the exclusion from any national scheme at the present time of the provision of dentures.

> Approved societies would then be faced with a toothless membership, liable to all sorts of further ill-health through want of the means of masticating food. The profession believe that this state of things would then almost immediately result in an agitation for a complete service, and that the end they have in view would thus be speedily obtained by taking two steps instead of one. There is ground for believing that neither the insured nor their societies would be content to accept this truncated form of a National Dental Service.

Medical Certificates for Dental Treatment Useless.

(App. XVIII., 29, 30.) Medical certificates for dental work appear to these witnesses to serve no other purpose than to transfer any fee up to 5*s.* from the pocket of the needy recipient of the benefit to the pocket of the doctor giving the certificate. In the thousands of cases where this formality has been required at the request of societies, the N.I.B.S. is unaware of any single case in which a certificate has not been forthcoming.

Optical Treatment.

(App. XVIII., 32–70.) The arrangements for this benefit made with the National Association of Opticians include the payment of a fee of 5*s.* for each person sent to an optician for examination and, where glasses are supplied, the price of the glasses. Spectacles in steel frames cost approximately 10*s.* 6*d.*, but usually something better is required.

The evidence suggests that a claim had been put forward by the medical profession that all insured persons receiving optical benefit should be first examined by an ophthalmic surgeon, or by some medical man, panel or other, who claims to possess knowledge and experience as regards diseases of the eye.

> It is said, in support of the medical contention, that 5 per cent. of all persons requiring glasses are suffering from a disease of the eye which would pass undetected by an optician, however qualified as an optician he might be. . . In reality, therefore, the claim of the medical profession is that the whole 100 per cent. of claimants for optical benefit should be compelled, in the first instance, to see a doctor, in order that the 5 per cent. amongst them who possess diseases of the eye, not ordinarily patent to an optician, might be ascertained and properly advised or treated.

For examining each person it was understood that the medical profession proposed that a fee of one guinea should be charged.

> (Q. 9120.) How is anybody to know whether it is one of the 5 per cent. or one of the 95 per cent. ?—I agree that is the difficulty, but we endeavour to get over that difficulty at a reasonable fee through the medium of our clinic.

An Optical Clinic.

(App. XVIII., 53–7.) The clinic to which reference is made is established in London with a West End ophthalmic surgeon in charge. He is remunerated on a basis which enables one guinea to be distributed over three patients. He is limited to 12 patients per session of two hours. If the surgeon feels that he would like to see patients more than once, no extra charge is made in respect of such additional attendance.

(Q. 9141.) A member of the Commission observed in the form of a question that he was associated with a clinic run under municipal auspices and conducted by one of the best-known ophthalmic surgeons in the West of Scotland at an average cost of 3*s.* 4*d.*

(Q. 9121–47.) With regard to the guinea fee contemplated by the medical profession, the witnesses said that although this might be worth while in the individual case in view of the 5 per cent. chance of serious disease, the proper course in a scheme of a national character would be to establish clinics of the kind which this society had already done. As regards examinations by opticians, they said :

> We have attempted outside of the clinic, as I pointed out, to see that it does not pay an optician to proceed with the case if he has the slightest doubt in connexion with it. He gets his money whether he supplies the glasses or not ; he gets exactly the same fee ; and therefore it does help to secure that the patient, if there is the slightest doubt of any disease of the eye, is referred to a competent ophthalmic surgeon.

Nursing.

(App. XVIII., 71–92.) Nursing as an additional benefit under the National Health Insurance Acts is described in this evidence as a comparative failure, mainly because contributions are already paid to nursing associations by the industrial section of the community, and they therefore see no reason for bringing their Approved Society into the matter, and also because of the fact that where continuous nursing is desirable it is provided in hospitals and other institutions to which the patient is removed, and the accommodation available to the industrial population in their homes practically prohibits resident nursing.

> From the experience of the past three years no society could justify the payment of a capitation fee for nursing in respect of the whole of its membership.

Hospital Treatment.

(App. XVIII., 93–8. Q. 9173–7.) The N.I.B.S. in 1921 took the initiative in getting into touch with the British Hospitals Association with a view to securing in-patient treatment for insured persons, and, in the result, a joint committee formed of representatives of Approved Societies and of members of the Executive of the British Hospitals Association was set up. The arrangements made by societies with the hospitals are of two kinds. Under one arrangement a definite sum is paid per week of in-patient treatment. In other cases the sum set aside by the society is divided amongst the hospitals each quarter in proportion to the number of members of the society treated in the institution during the quarter.

It was agreed that the payments made by the society should not prohibit the hospital from claiming a further payment from a patient in a position to afford it. The witnesses recommended that out-patient treatment for insured persons should be included as an additional benefit in view of the fact that many insured persons are sent to the hospital by the panel doctor. As regards finding the money, they suggested that—

> The relief which panel practitioners obtain by transferring insured persons to the out-patient wards of hospitals would seem to entitle the latter to some consideration in the distribution of the money provided for medical benefit under the Insurance Act.

Massage and Electrical Treatment.

(App. XVIII., 106. Q. 9193–5.) The witnesses thought that these should be added to the list of additional benefits, and said that there was a frequent and increasing number of recommendations by panel doctors for these forms of treatment.

> I have listened within the last two or three weeks to the figures given by one of the surgeons of St. Thomas's Hospital as to the extraordinary number of cases where massage treatment and radiant heat treatment have been provided by that institution not only to those who have been inmates of the institution, but also to out-patients. It really opened my eyes as to the extent to which these services are at present medically recommended and medically provided.

It was suggested that the provision of X ray photographs, blood tests, &c., should also be included in the additional benefits which might be given under the National Health Insurance Acts.

LONDON INTER-COLLEGIATE SCHOLARSHIPS BOARD. The Board announces that six medical entrance scholarships and exhibitions of an aggregate total value of £513, tenable in the Faculty of Medical Sciences of University College, and in the Medical Schools of University College Hospital, the London Hospital, and the London (Royal Free Hospital) School of Medicine for Women, will be offered. The examination will commence on June 30th next. Full particulars and entry forms may be obtained from the secretary of the Board, Mr. S. C. Ranner, the Medical School, King's College Hospital, Denmark Hill, London, S.E. 5.

MENTAL HOSPITAL ADMINISTRATION.

AN IMPORTANT CONFERENCE.

As briefly noted in our last issue a conference, convened by the Chairman of the Board of Control, was held in London at the offices of the Civil Service Commission on April 21st and 22nd for the purpose of considering: (1) the recommendations of the Departmental Committee's report on nursing in county and borough mental hospitals, and (2) the provision of further accommodation in mental hospitals.

The conference was opened by Mr. Neville Chamberlain, Minister of Health, who paid a tribute to the devotion shown by mental nurses in their difficult work, and emphasised the progress which has been achieved in the position and training of the nurses to-day. He reminded the conference of the work instigated by the Medico-Psychological Association in encouraging training and in examining mental nurses, and of the fact that over 17,000 nurses had obtained the Medico-Psychological Certificate in nursing during the last 30 years. The Minister referred to the Mental Treatment Bill for which he himself had been responsible, and to the disappearance of this Bill owing to the General Election of 1923. He led the conference to hope that after the Royal Commission now sitting had issued its report the Government would find means to promote legislation based upon that report.

NURSING SERVICE IN MENTAL HOSPITALS.

The discussion revealed considerable divergence of opinion on several of the recommendations contained in the report of the Departmental Committee, the principal aims of which were at times somewhat overlooked in the consideration of the effect of its details upon local interests. The questions involved are so important to the future and progress of mental nursing that recapitulation of some of the recommendations as set out in the report will not be out of place.

Aims of the Departmental Committee's Report.

In effect the report aims at the standardisation and unification of the nursing service on a national basis and bringing mental nursing into line with general nursing, of which it is an important branch.

A scheme for grading hospitals is put forward with a view to ensuring the development of really efficient training schools at those hospitals whose size, number of admissions, and general facilities offered sufficient scope and material for providing the training which the Departmental Committee regarded as fundamental to the future of the mental nursing service. The recommendations put forward—viz., the appointment of teachers or sister tutors, the adoption of nursing homes, lecture-rooms, &c., and the affiliation of mental and general hospitals, all have this end in view, and the question of reciprocity between mental hospitals is a necessary counterpart of the scheme. Such reciprocity would of necessity entail some sacrifice on the part of the smallest hospitals, but taking a long view it was thought that this would be more than compensated by the output of more and better trained nurses.

Another and important point is that it is only the prospect of a sound training and of a career that will attract applicants of the right educational standard, and, further, the encouragement of training in general as well as mental nursing is the only way to obtain a controlling staff of such integrity and reliability that the public may have complete confidence in regard to the proper care and treatment of mental patients.

The report recognises a distinction between the requirements of the nursing of actual physical and mental disease and the care of the chronic insane and generally healthy patients, and it is suggested that untrained attendants or orderlies could, if required, be employed for the latter. The Committee held that there were often both men and women educationally unfitted to take a nursing certificate who were notwithstanding specially gifted for this work, and that the supervision of the latter class by the trained nurses would present the best guarantee for the care and kindly treatment of the chronic insane.

The Committee took the view that the initial pay offered to probationers was a matter of less moment than the training and prospects in view, but strongly held that there was need for far greater difference than existed between the pay of trained and untrained nurses. A purely relative scale of pay is drawn up to illustrate this and is constructed to correspond with the rise in the pay of general hospital nurses.

Discussion at the Conference.

Dr. M. A. Collins (Bexley), who spoke on the question of remuneration, considered the pay suggested in the report to be inadequate. No doubt this is true as regards the type of nurse whose primary object in taking up the work is not the acquirement of a certificate.

Dr. W. F. Menzies (Cheddleton), in advocating that training should be compulsory, said that mental nurses must be made to feel that they are engaged for, and are getting, a training, and be taught to appreciate what this means for them. He deprecated the practice of having permanent night nurses, and thought that all nurses should take night duty in rotation and as part of their experience. He agreed with the report in advocating the introduction of general trained nurses into mental hospitals.

The conference seemed in favour of providing facilities for mental nurses to obtain a general hospital training. Miss Musson (formerly matron of Birmingham General Hospital) spoke in favour of reciprocity, but insisted on the necessity of mental nurses taking the full course, denying that their training with the limited bedside experience afforded could ever enable them to enter as second-year nurses. No one opposed the suggestion that after a period of probation nurses should be required to enter into a contract, such as applies in general hospitals.

On the important question of the hours of duty, the Report of the Departmental Committee shows a realisation of the varied difficulties involved, and the recommendations made are notably elastic. The conference provided no answer to the severe indictment made in the report against the two-day shift system. Dr. G. Clarke, who spoke in favour of this system, could only say that he did not believe these alleged defects really existed, and in maintaining that with efficient, well-trained nurses this system of dual control and divided responsibility worked satisfactorily, he seemed to ignore the fact that the average nurse of to-day is not of a high educational standard, and is not certificated. Dr. R. Eager (Devon) spoke against the double-day shift, and agreed with the finding of the report that for actual nursing of mentally and physically ill patients the undivided observation, control, and responsibility of the single turn of day duty was more satisfactory both from the point of view of the patient and of the administration of the ward. All will probably agree that the hours of actual and close attendance on very acute cases of mental disease should be curtailed to the utmost possible, and that the atmosphere of an acute mental ward requires regulations framed with the most liberal consideration for the nursing staff.

Dr. Henry Devine (Portsmouth), in speaking on the questions of obtaining suitable candidates and conditions of service, referred to the nursing of mental patients in other countries. He considered that mental institutions should, so far as possible, resemble our modern garden cities, and that those who had the care of the insane should be encouraged to introduce the methods and influences of ordinary life and occupation. He pointed to the fact that, apart from the acute forms of mental disorder, the great majority of patients now under certificate were in good physical health and did not require nursing so much as the companionship and control of persons of a sympathetic personality, chosen for general efficiency in normal associations. He personally thought, somewhat paradoxically, that to improve the mental nurse she must be abolished, and he believed that the general sources of trained nurses could, as abroad, provide mental hospitals with efficient nurses for the treatment of those patients in the hospital really requiring nursing. He suggested that this plan would become practicable if mental hospitals and the present Poor-law infirmaries came under one central committee of the local authority.

The nursing of male patients by women nurses was strongly advocated both by Prof. G. M. Robertson (Edinburgh) and by Miss Perry (matron of Cardiff City Mental Hospital), and the favourable experience of this practice all over Scotland and at Cardiff was placed before the conference. Attention was drawn to the comment in the Departmental Committee's Report that few of those superintendents who were opposed to this practice had ever tried it. On the other hand, in England the great difficulty at present is to obtain female nurses, whereas there is a steady supply of male nurses of a good type.

FURTHER MENTAL HOSPITAL ACCOMMODATION.

On the second day of the conference Alderman J. T. Travis-Clegg (Lancashire) and Mr. M. J. Godwin-King (Hellingly) spoke in regard to the extended use of Poor-law accommodation, and upon the greater use of Sections 55, 57, and 79 of the Lunacy Act, 1890, which deal with sending patients on trial, boarding-out, and discharge to care of relatives. Opinions were expressed against sending mental cases to Poor-law infirmaries and the workhouse observation wards, and the conference clearly deprecated the hardship of the system which prefaced the treatment of mental disorder by pauperisation. The advantages of placing Poor-law infirmaries and mental hospitals under one local authority, and the care of senile dementia without certification were considered.

Admission Hospitals and Convalescent Homes.

In opening the discussion on the provision of admission hospitals and convalescent homes, Dr. G. F. Barham (Claybury) referred to the feeling against the enlargement of existing mental hospitals, and to the views held by some against treating early cases at all at mental hospitals. In view of the large number of cases requiring treatment annually, beyond the scope of any possible provision of clinics, public or private, he held the opinion that properly isolated admission units on the villa system should be regarded as essential at every mental hospital, and that such units offered advantages not obtainable at small clinics. He referred to the schemes for linking up the mental hospitals with general hospitals and schools of medicine in different areas, and believed that thereby the reproach that psychiatry was out of touch with general medicine would be removed. Such provision and such schemes he regarded as essential to the development of mental hospitals, both as centres of treatment, for coöperation in research, and as training schools for mental nurses, and he reminded the conference of the important public service which the mental hospital had to perform, and with what benefit to the large population of these hospitals such an organisation would react. Linked up as a unit of a large medical organisation, he thought that there need be no fear of enlarging existing hospitals by providing admission units, and thereby erecting some of the new accommodation which the Chairman had told the conference was required.

Dr. Edwin Goodall (Cardiff) spoke against the treatment of early cases of mental disorder at mental hospitals. He believed that the prevention of insanity, research, and efficient treatment would never progress elsewhere than at psychiatric clinics attached to general hospitals and schools of medicine. He did not explain, however, how the scattered local requirements of the country, far distant from teaching centres, were to be met, nor how such organisation as he proposed was to cope with the great majority of cases.

Agreement was general as to the need for psychiatric clinics, which it is hoped will tend to diminish the number of cases requiring certification and treatment at mental hospitals. But it would appear that among the majority of experts this opinion in no sense carries with it a desire to impair the highest possible standard of humane and efficient treatment of certified cases—and of many voluntary boarders also, and it is widely held that the tendency to ignore and shut out the mental hospitals in any scheme for developing psychiatric medicine will certainly reduce that standard.

PARIS.

(From our own Correspondent.)

Surgeons' Fees in the Public Hospitals.

A RECENT incident has focused attention on a state of affairs which has gradually become perplexing and serious. The incident concerned a well-known surgeon attached to one of the most important hospitals. He saw in his own consulting-room a young woman to whom he recommended hospital treatment. She entered the hospital and paid the surgeon a fee, for which transaction he was blamed and the matter ended with his resignation from the hospital staff. There is, of course, much to be said on both sides in such a case, but its importance depends less on its individual merits than on its general significance. It is a local symptom of a constitutional disease. What is probably the crux of the matter is the lack of hospital provision for the middle classes—the people who can pay a moderate fee. At present they have often to choose between hospitals originally intended for the indigent and nursing homes whose charges are high. If we add that the surgeons attached to the public hospitals enjoy a high reputation, while some of the surgeons connected with private nursing homes are not exactly illustrious, it will perhaps be patent why many persons of moderate means find their way into the public hospitals. It is easy to call this state of affairs scandalous, but it is difficult to say who is responsible. There is a movement, which has its enemies as well as its friends, in favour of introducing a hospital tariff, according to which the patient of moderate means would be able to enjoy the benefits of first-class surgery in a public hospital at a charge within his reach. But what is to be the attitude of the first-class surgeon in these circumstances? Shall we see him becoming a full-time official, paid a salary by the hospital and disqualified from charging a fee in or outside the hospital?

The Students' "Strike."

The recent students' "strike," which began in the Faculty of Law of the University of Paris, is now happily ended, much to the credit of the University authorities and to the discredit of those who have been tempted to infuse party politics into the academic field. The origin of the trouble is past history now. The students held that the Government's choice of a lecturer in public international law was based less on the candidate's academic qualifications than on his political views, and they protested to the extent of boycotting the newly-appointed lecturer. Other faculties, including that of medicine, showed their sympathy with their fellow-students of the law, and a general strike throughout the student world of France was urged. The Minister of Public Health then took a serious step in suspending the Dean of the Faculty of Law, Prof. Barthélémy, from his office. It is impossible to say how this strike would have ended had not M. Herriot's Government fallen. Its fall, as far as the strike was concerned, may be regarded as singularly opportune. The new Government has not felt under any obligation to uphold the rulings of its predecessor in this matter, and it has made amends to the University for having interfered with the traditions of its independence. Prof. Barthélémy has been reinstated, and the students found guilty of rioting have been given an official pardon.

Interstitial Injection of Uriage Water.

On the basis that the water of Uriage (Isère) is isotonic with the blood serum, Dr. Larat advocates hypodermic injections of this water in its natural state, containing all its electrical properties, concurrently with other modes of administration. Interstitial injections of this water offer the three following advantages: (1) The ions which it contains carry electrical charges into the tissues; (2) the water has no hæmolytic action on the red blood corpuscles owing to the complete isotony which exists between it and the blood; and (3) the water introduces nascent colloidal sulphur directly into the tissues. The patients on whom this method was tried were suffering from various forms of eczemas, mainly chronic, or chronic rheumatism. 10 c.cm. of water are injected intravenously or subcutaneously every day until the symptoms definitely disappear.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

Rate-Aided Patients as Voluntary Boarders in Mental Hospitals.

IN a recent note on mental hospitals[1] mention was made of the difficulty encountered by the administrators of such institutions when dealing with indigent patients willing to enter the hospital as voluntary boarders. The Scottish Lunacy Act does not prohibit the reception of rate-aided voluntary boarders in mental institutions, but under existing arrangements the local authorities do not receive the lunacy grant for such persons unless they are "pauper lunatics." The parish councils are therefore naturally reluctant to make arrangements for admission to mental hospitals without certification. The board of directors of the Crichton Royal Institution, Dumfries, has taken a forward step in this matter by presenting a memorial to the Secretary for Scotland, praying for a modification of the Scottish regulations in regard to rate-aided cases along the lines of Lord Onslow's Mental Treatment Bill, which was introduced in the House of Lords in 1923, but which, through force of circumstances, was allowed to drop. The memorial puts forward statistics to show the difference between the outlook for voluntary and for certified patients. The recovery-rate at the Crichton Royal Institution of those admitted at their own request exceeds that of the rate-aided certified patients by 9·2 per cent. The memorial considers that a 10–15 per cent. improvement in the results of the mental treatment of rate-aided patients would be a conservative estimate of the benefit which would follow the facilitation of their entry as voluntary boarders. It also points out that the double stigmata of "pauper" and "lunatic" which must be incurred before a poor patient comes under competent mental treatment naturally causes postponement to the last possible moment. The increasing popularity of the voluntary system in this country is one of the most encouraging features of mental work during the last 20 years, and is rightly recognised by all concerned as a most important factor in the public health. The changes in English legislation which are expected to follow the report of the Royal Commission will almost certainly include a movement in this direction. Meanwhile all medical men will wish to support the attempt to secure the removal of a serious defect in the legal position in Scotland with regard to the poorer mental patient.

Diphtheria Prophylaxis in Edinburgh.

The preliminary observations of Dr. M. T. Benson, assistant M.O.H. of Edinburgh, regarding diphtheria prevention are distinctly encouraging. Recently he delivered a lecture, under the auspices of the Leith Parents' Association, giving his results in that work during the past year. The method described was that of inoculating children with a special "toxin-antitoxin" preparation. Three hypodermic injections were given at weekly intervals. In the vast majority of cases this is said to confer immunity for about six years, but the degree of immunity is not at its maximum until six months after the course of inoculations. In Leith Academy some 430 children, from 1 to 11 years of age, were dealt with in January and May of last year. Dr. Benson now reports, 14 months later, that of this group only one child has had diphtheria, and that a very mild attack. Furthermore, it had been noted in the case of this child that after the three toxin-antitoxin injections she had not been completely immunised, and a fourth protective injection had been given. She must therefore be regarded as a very highly susceptible case. In the same school some 120 children under 11 years of age had not been treated, and among these there were five cases of diphtheria reported during the same period, three of them being severe. Thus had the incidence of diphtheria been equally heavy in the two groups (treated and untreated cases), then with 5 cases occurring in the untreated group of 120 children one should have expected 18 cases in the much larger group of 430 treated children. Instead of 18 they had only one very mild case.

As a preliminary to the course of inoculations, the Schick test was carried out. Some 4500 children had the Schick test applied, and of these 65 per cent. between 5 and 10 years of age were found to be susceptible to diphtheria. Of those children between 1 and 5 years of age who were tested, 80 per cent. gave positive reactions. This is the dangerous age for diphtheria, 60 per cent. of the deaths in Edinburgh from that disease occurring in children under 5 years. The toxin-antitoxin inoculations given during this period should therefore be of special value. Fortunately, too, the younger the child the less reaction there is, though in no case has Dr. Benson seen a protective injection followed by severe or permanent ill-effects.

Leith Parents' Association.

In the diphtheria prevention campaign carried out in the past year in Leith great assistance has been given to the medical officer of health by a body known as the Leith Parents' Association. Membership of this Association is confined to parents and guardians of children attending Leith Academy, and the aims in view are "to enable parents to keep in touch with the educational affairs of the Academy and to stimulate interest in the wider aspects of education generally." The Association, which was founded in 1920, appoints "parent representatives" on the School Committee, and throughout the winter holds a series of lectures and social evenings. At present it has 190 members. This Association made it easy last year for Dr. William Robertson, M.O.H., to address the parents collectively on advisability of a campaign against diphtheria. His suggestions had all the more appeal, as a serious outbreak of diphtheria in the school in May, 1923, had affected between 30 and 40 children. The Schick test and toxin-antitoxin inoculation were explained, and, as a direct result, the parents of about four-fifths of the children agreed to allow them to be inoculated. The existence of similar associations in all schools could hardly fail to be a powerful adjuvant to public health administration in the country.

Obituary.

ARTHUR JOSEPH EAGLETON, M.D. Lond., M.R.C.P. Lond.,

BACTERIOLOGIST TO THE NEWARK EYE AND EAR HOSPITAL, NEWARK, U.S.A.

The many friends of Dr. Arthur Joseph Eagleton will regret to hear of his death recently at Newark, U.S.A., at the early age of 34.

Dr. Eagleton went from Rugby to Guy's Hospital, and graduated M.B., B.S. Lond. in 1913. He became pathological assistant to the surgical registrar in 1913 and was awarded the Golding Bird gold medal for bacteriology. While holding a house appointment at Guy's in August, 1914, he volunteered on the first day of the war and received a commission a few days later, when he went to France. He became bacteriologist to the Third General Hospital, B.E.F., and was also in the Fifteenth Field Ambulance. Later he became a specialist in cerebro-spinal fever in one area of England, publishing an article on the occurrence of meningococci in the air of army huts. After the war he gained the M.D. Lond. (in 1918), and he took charge of the bacteriological department of the Wellcome Physiological Research Laboratories, where he remained until 1923, when, finding it necessary to avoid the winter in England, he went as bacteriologist to the Newark Eye and Ear Hospital. Prior to his departure he had been secretary to the Pathological Section of the Royal Society of Medicine. He published several papers giving the results of his careful investigations into methods of standardisation of tuberculin, on the Schick test and active immunisation against diphtheria, and into the virulence of diphtheria bacilli. His work, particularly in connexion with the standardisation of tuberculin and the virulence of diphtheria bacilli, had already placed him amongst the most promising of the younger group of pathologists. In America he had commenced a lengthy series of well-planned observations and experiments on the diagnosis and treatment of ophthalmic tuberculous conditions and on protein sensitisation, and had carried the investigation far despite the handicap of considerable ill-health. His premature death deprives pathology of a keen worker of careful judgment who promised to make further contributions of great value to bacteriology.

His unselfish kindliness, sincerity, and his high personal ideals gained him the affectionate regard of his colleagues and of those who worked under him. He will be missed by a large circle of friends.

CHARLES ALFRED RAYNE, M.D. Lond.

By the death of Charles Alfred Rayne, at his residence in Lancaster on April 17th, at the age of 79, the borough of Lancaster loses its oldest medical practitioner. He studied at University College, London, qualified as M.R.C.S. in 1873, and in the same year took the M.B. of London University with honours in all examinations, and the M.D. in 1887. Before settling in Lancaster over forty years ago he had a varied experience as demonstrator of pathology in the University of Oxford, as an assistant physician of the Children's Hospital, Manchester, and resident physician at the Radcliffe Infirmary, Oxford. For 32 years he was honorary medical officer of the Royal Infirmary, Lancaster, and later honorary consulting physician. As early as 1875 he contributed a paper to The Lancet on Animal Heat in its Relation to Temperature Alterations in Certain Injuries and Diseases of the Nervous System, and in 1876 a paper on the Influence of Hydrate of Chloral in Certain Forms of Convulsive Disorders, and again in 1889 a paper entitled What is Life? In The Lancet, 1903, he described a treatment of goitre by the use of distilled or rain-water.

Public Health Services.

Health of the City of London.

The resident population of the City of London is so small—viz., 13,300 (to be compared with a day population of over 364,000)—that the statistics fluctuate much from year to year. Births during 1924 numbered 94, deaths 151, and deaths of infants 11, equivalent, respectively, to rates of 7·1, 11·3, and 117. In his report for this year Dr. William J. Howarth deals with many interesting subjects.

The decreasing number of dwellings suffer in their sanitary environment from the obstructive effect of the increasing number of high business premises and warehouses. The workers wish to live near their work, but suitable sites cannot be found for them within the City boundaries. Accommodation is needed for the housing of some 1500 persons, mostly living in houses unfit for human habitation. As a beginning a site has been purchased in Shepherdess-walk, Shoreditch, which will house about 500 persons. It is estimated that this first instalment will cost about £95,000 and will involve a charge of about one-ninth of a penny on the City rates for 60 years. The Sanitary Committee recommend that no Government contribution be applied for, but that the whole cost be borne by the City.

A system of voluntary registration of barbers' shops was begun in 1904. At one time there were 32 such establishments on the register; the number is now reduced to five, as most of them have been transferred to the Statutory Register, provided under the L.C.C. Acts of 1915 and 1920. Dr. Howarth points out that the amount of deposit falling in the City from atmospheric pollution in the month of July only was 53·6 tons. He says "the cost of electricity is still far too great for its general use," but that he "believes the substitution of gas for coal and coke in restaurants and business premises is practicable and might be more generally adopted if the gas companies encouraged its greater use" by arranging a special rate for such premises. During excavations in Farringdon-street a considerable quantity of human remains was found at a deep level, possibly indicating the site of an old burial ground for St. Bride's parish. Out of 39 samples of milk tested for tubercle five (or 12·8 per cent.) gave a positive result. The precautions taken in milk sampling to obtain a fair sample without contaminating the milk are described.

As usual, Dr. Howarth devotes much space to the questions concerned with the meat-supply. During the year caseous lymphadenitis, a condition simulating tuberculosis, was found to be unduly prevalent among sheep carcasses received from Argentina. The total number of carcasses found to be affected during the first nine months of the year was 88, not a large proportion, as Dr. Howarth points out, among the 70,000 tons of carcasses received. The lesions were chiefly located in the prescapular (51) and precrural (25) lymph glands, indicating the generalisation of the disease. This disease is not uncommon in Australia, but fewer cases were found among Australian carcasses, owing to the system adopted at the time of slaughter, of careful palpation of the lymph glands in the prescapular, precrural, and superficial inguinal regions. Consignments of chilled beef have been received from Canada. This meat is carried at only 2° or 3° below freezing-point and remains unfrozen. It does not require preliminary thawing or exude juice on cutting, and a period of only 12 or 13 days elapses between slaughter and sale in the market. The meat was in excellent condition, but the carcasses might have been of primer quality. It is stated, however, that a loss was sustained on this attempt to establish a Canadian chilled meat trade, and that it is more profitable to send the live animals to Birkenhead. The Netherlands Government have recently issued an order prohibiting the importation of meat from countries which have no national system of meat inspection, and arrangements are being made through the Ministry of Health to comply with these regulations as far as the abattoirs at Aldgate and Islington are concerned. At the invitation of the Netherlands Government, a deputation from the City Corporation visited Holland in April, 1924, to observe the methods of meat inspection adopted there. As a means of determining the frequency of antenatal tuberculous infection in calves, a careful record is being kept of the location of tuberculous lesions in calves under the age of 5 months, and it is hoped in future to be able to classify the cases in three sections—viz., (*a*) those obviously postnatal; (*b*) those probably antenatal; and (*c*) those doubtful in origin. An analysis of the organs affected in the case of 79 cows, all under the age of 9, showed that in 23—i.e., 29·1 per cent.—the udder was affected.

In accordance with the recommendation of the Departmental Committee on meat inspection, the unequalled educational opportunities afforded by Smithfield Market are to be used systematically for the training of meat inspectors. Trial lectures have already been held, with a very good attendance. No charge will be made for the lectures. The quantity of meat passing through Smithfields in 1924 was the highest ever known—480,520 tons. Of this amount 21·8 per cent. was British and Irish, 46·8 per cent. from Argentina, 18·9 per cent. from New Zealand and Australia, and 12 per cent. from Holland and other sources. British meat still shows the lack of systematic meat inspection in the country. "The quality, grading, and dressing of Australian beef were, with exceptions, still far from being in the same class as Argentine beef." Many of the quarters of Australian beef were from aged cattle and many of the carcasses of mutton were those of old ewes, no doubt retained for their wool value. New Zealand mutton and lamb maintained its reputation, but the beef was a negligible quantity, generally from old cows and very badly dressed. Holland takes pride of place for depositing in Smithfield the right type of pig carcass, with a long back and loin and short plump legs, from a pig which arrives quickly at the desired weight. Intending British pig-breeders are advised to take this type as a model. The Court of Common Council lodged a protest with the Ministry of Health against the proposals contained in the Factories Bill of 1924, which would have transferred some of the existing powers of control from the sanitary authorities to the factory inspectors.

Rat repression has received attention, but Dr. Howarth lays stress on the weak part of the Act, by which the responsibility for necessary structural alterations is not thrown on the owner and also the difficulty arising from multiple occupancy. Reference is made to the method of locating the body of a dead rat by releasing blue-bottles in the room and watching where they settle. Unfortunately, the trouble in the City with dead rats usually arises in the winter time, says Dr. Howarth, when blue-bottles are not procurable. Another method, available when there is a ceiling below, is to look for a patch of discoloration. Notwithstanding the unsatisfactory state of the law, the various measures of rat repression adopted appear to have prevented an increase in the rat population of the City.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED APRIL 18TH, 1925.

Notifications.—The following cases of infectious disease were notified during the week, namely :—Small-pox, 135 ; scarlet fever, 1543 ; diphtheria, 845 ; enteric fever, 36 ; pneumonia, 1344 ; puerperal fever, 74 ; cerebro-spinal fever, 14 ; acute poliomyelitis, 2 ; acute polio-encephalitis, 1 ; encephalitis lethargica, 52 ; continued fever, 1 ; dysentery, 3 ; ophthalmia neonatorum, 129. There were no cases of cholera, plague, or typhus fever notified during the week. The number of small-pox cases showed a decrease of 14 from the number for the preceding week.

Deaths.—In the aggregate of great towns, including London, there were 3 deaths from enteric fever, 134 from measles, 13 from scarlet fever, 114 from whooping-cough, 27 from diphtheria, and 162 from influenza, as compared with 221, 242, 281, and 304 in the four preceding weeks. In London itself the deaths fron influenza numbered 16, from whooping-cough 30, and from diphtheria 8.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Lt. T. N. D'Arcy to be Surg. Lt.-Comdr.

ROYAL NAVAL VOLUNTEER RESERVE.

Proby. Surg. Sub-Lts. to be Surg. Sub.-Lts. : C. M. Brooks, M. J. Arnott, and D. R. F. Bertram.

ROYAL ARMY MEDICAL CORPS.

Lt.-Col. E. E. Parkes, half-pay list, late R.A.M.C., is restd. to the estabt.

RESERVE OF OFFICERS.

Maj. A. E. Thorp, having attained the age limit of liability to recall, ceases to belong to the Res. of Off.

TERRITORIAL ARMY.

Lt.-Cols. C. I. Ellis and E. C. Montgomery-Smith (from R.A.M.C., T.A.) to be Cols.

Capts. R. J. Bruce (late R.A.M.C.) and R. J. W. A. Cushing (late R.A.M.C., T.A.) to be Capts.

Lt. A. Pain to be Capt. J. O. Moffat to be Lt.

TERRITORIAL ARMY RESERVE OF OFFICERS.

Maj. J. A. Morris (late R.A.M.C., T.A.) to be Maj.

ROYAL AIR FORCE.

Flight Lt. F. E. Johnson is granted a permanent commission in the rank stated.

Flight Lt. R. H. Wace relinquishes his temporary commission on ceasing to be employed.

INDIAN MEDICAL SERVICE.

Capts. E. Calvert, R. Sweet, F. Phelan, Nawin Chand Kapur, Narayan Krishna Bal, and Haji Sulaiman Gulamhossein Haji to be Majs.

Temp. Lts. Jagdish Sahai, Har Sarup Gupta, and Piyare Lal Burman to be Temp. Capts.

Satya Raju Chittoory to be Temp. Lt.

The King has approved the retirement of Col. F. Wall, and Lt.-Cols. E. C. C. Maunsell and F. D. S. Fayrer.

Lt. Birendra Nath Hajra relinquishes his temp. commission.

Homi Edulji Variava and Muthu Ramkrishna Grandhi are granted the rank of Capt. on relinquishing their temp. commissions.

DEATHS IN THE SERVICES.

Surgeon Vice-Admiral Sir Arthur William May, who died on April 21st, in his seventy-first year, at his residence in Cornwall, was a late Director-General of the Medical Department of the Royal Navy. The son of the Rev. H. T. May, Fellow of New College, Oxford, he was educated at Sherborne School and at King's College Hospital and, after qualifying in 1878, entered the Royal Naval Medical Service as surgeon. He was on active service in the Egyptian War of 1882 and was awarded the medal and Khedive's bronze star. He also took part in the Suakim Expedition two years later, and with the Nile Expedition for the relief of General Gordon. For services under Sir Charles Beresford for the relief of Sir Charles Wilson he was mentioned in despatches, having distinguished himself in ministering to the wounded under fire. On his return home he was appointed surgeon of the R.M.L.I. at Portsmouth and subsequently served in Australia ; in the cruiser *Volage*, in the training squadron ; at the Naval Hospital, Gibraltar ; at Devonport ; and in the battleship *Empress of India*. From 1901 to 1904 he was P.M.O. of the training ship *Britannia* at Dartmouth, and later took charge of the hospital at Gibraltar. Having reached the rank of Deputy Inspector-General, he was appointed Deputy Inspector of the Medical Department at the Admiralty in 1905, and after holding charge of the Royal Naval Hospitals, first at Portsmouth and afterwards at Chatham, he succeeded Sir James Porter in 1913 as Director-General, retiring in 1917. After the war he became closely associated with the Comrades of the Great War Association and with the British Legion, of which he was national vice-president. Sir Arthur May, who was Hon. Physician to the King, a deputy lieutenant and a magistrate for Cornwall, was awarded the C.B. in 1911 and promoted to K.C.B. in 1914. He was also a Knight of Grace of St. John of Jerusalem and held the Belgian Order of Leopold and the Japanese Order of the Sacred Treasure of the first class. He married, in 1892, Adelaide, a daughter of William Baldock, of Cooling Castle, Kent.

Correspondence.

"Audi alteram partem."

APPENDICITIS AND THE APPENDIX STUMP.

To the Editor of The Lancet.

Sir,—The correspondence which followed Mr. Rendle Short's excellent clinical lectures on appendicitis (The Lancet, Jan. 31st and Feb. 7th) dealt mainly with diagnosis and post-operative treatment of the disease, and a point in operative technique passed unchallenged. Mr. Rendle Short states that "the stump of the appendix must be securely buried or otherwise shut off from the peritoneal cavity. It is useless to trust to drainage to make good any deficiencies in this direction." But, in two of the most recent text-books of the day these paragraphs occur: "It is not always wise to attempt invagination of the stump owing to the danger of disturbing adhesions, and it is sometimes impossible if the inflammatory changes have rendered the tissues of the cæcum very friable"; again, "attempts to accomplish invagination of the stump in face of difficulties had better not be persisted in too long as they may result in the loss of valuable time and unduly prolong the operation" (Taylor); and finally, "in general suppurative peritonitis from perforative appendicitis or from rupture of a circumscribed abscess into the free peritoneal cavity I proceed as follows: Open the abdomen as in a case of primary appendicitis, locate and amputate the appendix to prevent further leakage. All manipulation of the intestine should be avoided" (Murphy).

In the most acute types of the disease, therefore, simple ligation and amputation of the appendix is not only recognised as a safe procedure, but some surgeons consider it the method of choice. The question then arises as to whether invagination of the stump is ever necessary. A debate on this matter was opened by Mr. de Martel at the Society of Surgery in Paris in December, 1921. At the end of three months' discussion no unanimity was reached, for each side massed their thousand cases in support of their views.

The "non-buriers" of the stump hold that an abscess not infrequently forms in the wall of the cæcum due to the enclosure of the stump in a closed cavity, or from actual perforation of the cæcal wall by the loops of the invaginating suture. Mr. de Martel stated that his experiments on the cadaver showed that the perforating point in the cæcum was not possible to avoid even by the most adroit surgeons. The mildest result of this may be a localised abscess in the abdominal wall. A perusal of this discussion makes clear that invagination of the stump is an unnecessary manœuvre, that simple ligation with adequate disinfection is quite sufficient. Even the "buriers" admitted that rigorous disinfection made invagination unnecessary and that the simpler method was preferable to inefficient burying of the stump. In America Shelton Horsley has advocated this method for many years, and in his work on "Operative Surgery" there is an instructive illustration showing the fate of the encapsulated invaginated stump compared with that treated by simple ligation.

In England recently Mr. Patterson, in his interesting presidential lecture on the Lure of the New, asks whether certain methods of technique may not be simplified without loss of efficiency. In appendicectomy he states that in acute cases he simply ligatures the appendix and cuts it off to gain precious time, while in the chronic he considers invagination of the stump quite unnecessary from the point of view of safety, though it is neat and may diminish the risk of adhesions.

For over 20 years we invaginated appendix stumps, but for the last five years we have used this simpler method in every type of appendicitis—from the chronic interval case to the gangrenous type with generalised peritonitis. Simple in the extreme, for often two ligatures suffice, one through the meso-appendix, the other round the base of the appendix, this method has never given us any anxiety, no fistula has resulted, nor any post-operative complication. The occasional pricking of vessels in the cæcal wall with the formation of the troublesome hæmatoma sometimes seen is avoided, while the operator is freed from the misdirected efforts of an assistant pushing in an obstinate stump, which sometimes refusing to be easily invaginated seems to ask simpler treatment. The sterilisation, however, must be carefully done by cautery, pure carbolic acid, or iodine, it seems immaterial which agent is used. As all our patients have been private cases we have been obliged to follow their convalescence personally, and we are convinced that this method reduces post-operative flatulence to a minimum; it is, in fact, usually absent, probably because so little manipulation of the cæcum is needed with this technique.

Our experience therefore leads us to think that far from being a deficient method, simple ligation of the appendix with adequate sterilisation of the stump is the method of choice in every type of the disease.

We are, Sir, yours faithfully,

Ian Macdonald.

W. A. Mackay.

Huelva, Spain, April 20th, 1925.

SCARLATINIFORM RASHES IN INFLUENZA.

To the Editor of The Lancet.

Sir,—With reference to Dr. Charles Birch's communication concerning cases of influenza masked by scarlatiniform rashes I should like to record the following interesting case.

A patient, a male aged 30, was seen by me during the recent influenza epidemic. He complained of aching pains all over the body and especially in the larger joints. There was intense headache and general malaise. Temperature 102° F. Tongue thickly furred. Influenza was diagnosed. Two days later he developed a blotchy erythematous rash, appearing first on the neck, chest, and upper limbs, spreading to the abdomen and lower limbs later. The rash eventually appeared on the face which, meantime, had been deeply flushed.

The skin over the whole body remained thus affected for three days, when the rash rapidly disappeared, leaving a brownish mottling which cleared at the end of a week. The buccal mucosa was red, swollen, and velvety; the tonsils inflamed. The throat was slightly painful—more so on deglutition. Red papillary patches appeared here and there on a tongue previously thickly coated with white fur.

The diagnosis of influenza was maintained throughout, even though the rash and certain other features of the case suggested otherwise, because I considered the illness differed atypically from scarlet fever in several important respects. There was no exfoliation, and the patient made a speedy and uninterrupted recovery. No case of scarlet fever occurred afterwards, and Dr. Yeoman, M.O.H. for the district, who saw the case and substantiated my findings and diagnosis, informed me that there had been no other cases of scarlatina before or after in the immediate vicinity. The drug treatment precluded any possibility of the rash or symptoms being due to that source.

I am, Sir, yours faithfully,

Donald M. Sutherland, M.B., Ch.B.

Stokesley, Yorks, April 27th, 1925.

Climatological Congress.—From August 17th to 22nd a Climatological Congress will be held in Davos, Switzerland, arranged by the local Research Institute. The subject of the Congress will be the Significance of Climate in its Physical, Physiological, and Therapeutical Aspects. Those desirous of contributing papers on any branch of the subject in which they are specially interested, or wishing further particulars concerning the programme and arrangements, are invited to communicate as soon as possible with the Secretary of the Congress, Dr. Vogel-Eysern, Davos-Dorf, Switzerland.

Medical News.

UNIVERSITY OF CAMBRIDGE: *Examination for the Diploma in Public Health.*—The following candidates have now satisfied the examiners in both parts of the examination :

John A. Charles (distinguished in the principles of hygiene, distinguished in the application of sanitary science), Duncan C. de Fonseka, George K. Fulton, Sidney M. Hattersley (Emm), Hugh A. Sandiford, and Arthur J. Smyth (Emm.).

UNIVERSITY OF GLASGOW. — At the graduation ceremony held on April 22nd the following medical degrees were conferred :—

M.D.—James L. Halliday (high commendation), Hector M. Walker (commendation), Hugh C. Davies, Thomas D. Hunter, and Alexander H. Stewart.

M.B., Ch.B.—With honours : Raymond A. Currie, Morton A. Foulis, and James A. Imrie. With commendation : Robert N. Walker, Charles M. Morton, Robert G. Hutchison, Cecil W. Anderson, Robert Ramsay, James M. Stobo, Edna W. Bruce, Peter D. Thomson, Arthur G. M. Murdoch, Robert S. Hynd, and Henry J. Scott.

Malcolm Allan, Bessie R. Barr, John Barr, Michael J. Bastible, Daniel M. Bell, Joseph A. Bell, Norman L. Bennie, Ann K. Black, Alexander D. Boyd, William Brock, Alexander R. Brown, Douglas Brown, Hamilton Brown, David R. Campbell, Alexander Clark, Alexander F. Clark, John S. Clark, Douglas H. Clutterbuck, Edgar Cochrane, James M. Cormack, Elizabeth Coupland, John Craw, James Crawford, Cochrane Cross, James Cunningham, Janet B. Cunningham, Maurice Curran, Eileen M. Deane, Robert C. Deans, Malcolm C. Douglas, George D. Drever, Lucy M. Dron, William W. Ferguson, John W. Ferrie, Alexander J. Finlayson, John D. Finlayson, John Flynn, John C. Forsyth, John M. Forsyth, Charles A. I. Fuge, Elizabeth S. Galbraith, William D. Gillespie, Thomas L. Gordon, Robert G. R. Grieve, James B. Harrower, Robert Harvey, Ellen M. Hegarty, James Hill, George Hutcheson, Thomas Imrie, Robert F. Innes, Dora Karnovski, Donald H. Kinmont, Neil M. Lees, Alexander Leiper, Moses Lurie, Thomas B. M'Aleer, Donald A. P. Macalister, Archibald MacArthur, Ian E. MacArthur, James C. Macarthur, Alexander G. M'Callum, Duncan M'Callum, Neil M'Diarmid, Peter A. M'Dougall, David T. M'Gibbon, Joseph MacGowan, Eneas J. MacIntyre, Neil D. Mackinnon, Alexander MacLachlan, Sydney H. P. M'Lauchlan, Neil M. MacLean, Elizabeth V. MacLeod, Hector A. Macmillan, William M'Millan, Angus S. M'Neish, Thomas S. Meighan, William Meiklejohn, Isomay Mitchell, James Munn, David S. Murray, James A. Murray, Stanley D. S. Park, John Paterson, William Paterson, John Peter, Margaret I. Prangnell, Leslie W. Quelch, Hugh C. Reid, Thomas G. Rennie, Andrew Roberts, Guy S. Robertson, Gertrude R. S. G. Smith, Hugh Smith, John Smith, John T. Smith, William H. Smith, William F. Stalker, Gilbert R. Stark, Norah M. Steele, Thomas J. Steven, William R. M. Stevenson, Malcolm Stewart, Thomas F. Strang, Daniel Struthers, John W. Struthers, William Tait, Matilda D. Tennent, David Thomson, James Thomson, Agnes B. T. Warden, John Warren, Alexander W. Watt, James D. Wilson, John Wilson, George M. Wyburn, and James Young.

On April 21st Bellahouston gold medals for eminent merit in theses for the M.D. were awarded to George A. Allan, David Campbell, and Robert D. Gillespie.

UNIVERSITY OF LONDON. — A lecture on the Projection of the Retina in the Brain will be given at Charing Cross Hospital Medical School by Dr. B. Brouwer, professor of neurology in the University of Amsterdam, at 5 P.M. on Friday, May 15th. The lecture will be delivered in English, and Mr. J. Herbert Fisher, senior consulting surgeon, Moorfields Eye Hospital, will take the chair. Four lectures on Chemical Control of Certain Bodily Functions will be given at St. Bartholomew's Hospital Medical College by Dr. H. H. Dale, F.R.S., on May 15th, 19th, 22nd, and 26th, at 5 P.M. At the first lecture the chair will be taken by Sir Holburt Waring. Admission to these lectures is free.

Thomas Smythe Hughes Medical Research Fund.—Applications for grants from this Fund, accompanied by the names and addresses of two references, must be made to the Academic Registrar of the University (from whom further particulars may be obtained) not later than June 15th.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—A special course in Infants' Diseases, for medical officers of welfare centres and others, will be given at the Infants Hospital, Vincent-square, Westminster, from May 18th to 30th. Copies of the programme may be obtained from the Secretary of the Fellowship, 1, Wimpole-street, London, W.

The Fellowship will begin a summer session of lectures at the house of the Royal Society of Medicine on Thursday, May 7th, when Sir Henry Gauvain will give a lantern lecture on Heliotherapy in Surgical Tuberculosis at 5.30 P.M.

INDIAN MEDICAL SERVICE DINNER FUND.—The annual dinner of the Indian Medical Service will be held at the Trocadero Restaurant on Wednesday, June 17th, Lieut.-Colonel A. W. Alcock, F.R.S., in the chair. Tickets and all particulars may be obtained from the joint honorary secretary, Colonel J. J. Pratt, I.M.S. (ret.), 18, Nevern Mansions, Warwick-road, London, S.W. 5.

ROYAL COMMISSION ON LUNACY AND MENTAL DISORDER.—The next meetings will be held at 5, Old Palace Yard, Westminster, on May 4th and 5th, beginning at 10.30 A.M. each day.

QUEEN MARY'S (ROEHAMPTON) HOSPITAL. — On Wednesday, May 6th, at 3 P.M., H.M. Queen Mary will open the extension of the hospital at Roehampton House, Roehampton, S.W.

THE Chemists' Exhibition and Empire Drug Trade Mart will be held from Monday, May 4th, to Friday, the 8th, at 11 A.M. to 8 P.M., at Holland Park Hall, Holland Park Avenue, London, W.

ROYAL COMMISSION ON NATIONAL HEALTH INSURANCE.—The twenty-fifth meeting of this Commission was held at the Home Office, Whitehall, on April 23rd, Sir Andrew Duncan in the chair. Evidence was given on behalf of the National Sailors' and Firemen's Union by Mr. Chambers, who dealt with the special arrangements for seamen. The Loyal Order of Ancient Shepherds, represented by Mr. John Grieve, Deputy Chief Shepherd, and Mr. A. J. E. Saunders, General Secretary, were examined on questions of extensions of benefit, pooling of surpluses, organisation of branch societies, &c. The Association of Approved Societies, representing about 150 societies and 1,500,000 members, gave evidence through Mr. J. E. Hilton, Mr. Robert Smith, and Mr. F. A. Goodwin on matters affecting their constituent societies. Thereafter Miss Amy Cameron and Miss Margaret Hamilton were examined on behalf of the Standing Committee of Scottish Insured Women as to a variety of matters affecting women's interests in health insurance. Proof copies of the oral evidence and the relative statements submitted at the meeting of March 26th and April 2nd are now on sale at H.M. Stationery Office (4*s.* 6*d.* and 2*s.* 3*d.*).

INTERNATIONAL SOCIETY OF MEDICAL HYDROLOGY. The annual general meeting of this society, attended by the representatives of eight countries, took place in Paris, April 20th–21st. Dr. Gustave Monod (France) was elected President for the year in succession to Dr. Fortescue Fox (England). On the motion of Dr. Van Breemen (Holland), a committee was appointed to report upon the incidence of chronic rheumatic diseases in Northern Europe as shown by official returns in England and Sweden, and upon their treatment by physical methods. The following subjects were discussed in Prof. Carnot's laboratory at the Faculté de Médecine : (1) Insulin Treatment in Relation to Medicinal Waters, introduced by Drs. Chabanier (France), Poulton (England), and Epstein (New York) ; (2) the Spa Treatment of Rheumatism of Traumatic Origin, introduced by Drs. Schmidt (Czecho-Slovakia) and Vincent Coates (England). Demonstrations and lectures were also given at the Ecole de Médecine and the Collège de France by Dr. Lepape and Prof. Desgres. The society was entertained at a banquet by the Bienvenu français. An invitation was received from Czecho-Slovakia to hold the next annual meeting of the society in that country.

IRISH FREE STATE: TRAVELLING FELLOWSHIPS IN PUBLIC HEALTH.—The conditions of the Travelling Fellowship in Public Health offered by the Rockefeller Foundation have been published. Three Fellowships are offered in anticipation of the appointment of county medical officers of health under the Local Government Act, 1925. The Fellowships are open to any duly qualified medical practitioner of Irish nationality or parentage who holds a registered or a registrable diploma or degree in sanitary science, public health, or State medicine. The Minister for Local Government of Public Health will set up a committee of experts to consider the applications and to select the most suitable candidates for these Fellowships. The selected candidates will be required to submit to medical examination and to give an undertaking to act, if appointed, as county medical officer of health for a period of at least three years at an initial salary, or combined salaries, of not less than £800 per annum inclusive, with an allowance for travelling expenses. Applicants for the Fellowships must furnish particulars of general educational attainments, professional qualifications, and experience in public health work, age, state of health, service in the National Army, knowledge of Irish, and testimonials of character. The candidates who are selected for travelling Fellowships must be prepared to go to America towards Sept. 1st, so as to arrive at the beginning of the academic year. The course of studies will occupy a period of about eight months.

A DINNER in aid of the funds of the Infants Hospital, Vincent-square, will be held at the Guildhall on May 8th, at 7 for 7.30 P.M., Prince Henry presiding.

UNIVERSITY OF BIRMINGHAM.—The Ingleby lectures will be delivered on May 6th and 13th, at 4 P.M., in the Medical Lecture Theatre, Edmund-street Buildings, by Dr. J. G. Emanuel, on Auricular Fibrillation. Members of the medical profession are invited to attend.

INSTITUTE OF PATHOLOGY AND RESEARCH, ST. MARY'S HOSPITAL.—A course of lectures on Pathological Research in its Relation to Medicine has been arranged for the summer session. These lectures are being given in the Lecture Room of the Bacteriological Department of the Institute on Thursday afternoons at 5 P.M. Sir Almroth E. Wright, F.R.S., delivered the first lecture on April 30th on Chemo-therapeutical Agents. Subsequent lectures will be as follows: May 7th, Prof. W. E. Dixon, F.R.S., Cerebro-Spinal Fluid with Special Reference to Pituitary Secretion. May 14th, Mr. A. T. Glenny, B.Sc., the Principles of Immunity as Illustrated by Protective Inoculation against Diphtheria. May 21st, Prof. E. W. Macbride, F.R.S., the Inheritance of Acquired Qualities. May 28th, Dr. W. E. Gye, the Filterable Viruses. June 4th, Sir Arthur Keith, F.R.S., the Structural and Functional Disorders of the Great Bowel. June 11th, Prof. J. Joly, F.R.S., Radiology. June 15th, Dr. R. Robison, F.I.C., the Chemistry of the Calcification of Bone. These lectures are open to all members of the medical profession and to all students in medical schools without fee.

THE LATE DR. J. DON.—James Don, M.D. Aberd., of Newcastle, who died, aged 61, on April 23rd, after a short illness, was honorary senior surgeon to the Newcastle Throat and Ear Hospital and had been connected with that institution for about 30 years. Born in Aberdeen, he graduated M.B., C.M. at the University of his native town in 1888, and obtained the M.D. with honours in 1890. Two years later he went to Newcastle, where he set up in general practice; he was particularly attracted towards throat and ear work, and for the past four years he devoted himself exclusively to that special branch of medicine. Dr. Don took an active interest in medical politics. He was secretary of the North of England branch of the British Medical Association for about ten years, terminating his office last year, and he was at one time chairman of the Newcastle branch. During the war Dr. Don acted as aural surgeon at the Pendower V.A.D. Hospital, and was secretary of Medical War Committee. A member of the Panel Committee, his activities brought him into direct connexion with most doctors in the two northern counties.

PUBLIC HEALTH PROPAGANDA.—The Minister of Health received on April 23rd a deputation from the Society of Medical Officers of Health, introduced by Dr. John Wheatley. The deputation represented that they in their capacity of men of scientific training, in constant touch with the general public, thought that statutory provision should be made for local authorities to carry on health propaganda, and as a next stage a central body should be set up to advise local authorities on the matter. The society thought that in their special position they would be able to give valuable help to such a central body, and that medical officers of health should themselves be included in its membership. The Minister, in reply, said that he fully agreed with the deputation as to the necessity for propaganda on health questions, and he gave his assurance that he proposed to take steps to have the necessary powers conferred on local authorities forthwith. He also agreed that some sort of central body could give valuable assistance; and when the necessary legislation had been passed he would give careful consideration to the question of the proper constitution of such a body and the functions which should be assigned to it.

REPORTING OF MENTAL DEFECT.—Circular 1359, just issued by the Board of Education to local education authorities, deals with Reports on Mentally Defective Children. "In view of the importance of correct diagnosis" (in the words of the circular) a new Form 306M. is introduced to take the place of Schedule F, which the Board require to have completed in certain cases of mentally defective children. The new form does not differ much from the old, except that more details are expected, the suggestion being made that part of the information required may be collected by someone other than the certifying officer. Alternative forms from local authorities who desire to use their own will not be refused, provided the information given is substantially the same. A revised Form 41D., incorporating certain recognised scholastic attainment tests, is also issued, to be filled up by head teachers for the information of the certifying officer. Form 311M. is the form of the medical certificate prescribed by the Board for the purpose of notification of an idiot or an imbecile to the local authority under the Mental Deficiency Act, 1913. Form 312M. is a similar certificate for use when notifying a moral imbecile. These two forms also accompany the circular, which goes on to draw the attention of local authorities to their legal obligations of first referring to the Board all cases—other than idiots, imbeciles, or moral imbeciles (unless they are blind or deaf)—before notifying to the Mental Deficiency Committee. A warning is also sounded that in view of the definition of "moral imbeciles" in Section 1 (*d*) of the Mental Deficiency Act, 1913, it is only in rare and exceptional circumstances that a child of school age could properly be certified as a "moral imbecile." Copies of these forms can be obtained on application to the Board of Education, Medical Branch, 54, Victoria-street, London, S.W. 1.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

THE BUDGET.

PARLIAMENT reassembled after the Easter recess on Tuesday, April 28th. Mr. CHURCHILL, Chancellor of the Exchequer, introduced the Budget in the House of Commons. In the course of his statement he said the total national expenditure for the year 1925–26 was estimated at £799,400,000, being £9·4 millions more than last year's Budget estimate and £3·7 millions more than the actual expenditure of last year. In future they ought to aim at a reduction in expenditure of at least £10,000,000 a year. An increase in the motor vehicle duty of £1,250,000 would carry this duty to £17,500,000. It was proposed that Great Britain should resume its international standard as a gold standard country from the date of the Budget statement. Bank of England and Treasury notes would only be convertible into gold coin at the option of the Bank of England. The country had a gold reserve of £153,000,000. Increases in death duties would be proposed which would yield £10,000,000 in a full year and £4·5 millions the first year. The total yield of new taxes would be £10,230,000 in 1925–26 and over £20,000,000 in 1926–27. The surplus for 1925–26 was thus increased by £10,230,000 to £36,830,000, and a permanent addition to revenue was secured worth £20,000,000 more in 1926. Legislation would be proposed making improvements in the machinery for income-tax appeals by charities in this country.

Contributory Pensions.

It was proposed to inaugurate a new scheme of widows' pensions and old age pensions which would be contributory and cover broadly the 15,000,000 insured persons within the existing health insurance scheme. These 15,000,000 persons with their dependants comprised 30,000,000, or about 70 per cent. of the nation. The contributions would be from employer and workman 4*d.* per week each, and from employer and workwoman 2*d.* a week each. If these contributions had been made by all persons in the health insurance scheme from the age of 16, a self-supporting scheme would afford pensions of 10*s.* a week to widows of insured persons together with certain allowances for children and orphans, and secondly, 10*s.* per week to all insured persons and their wives at the age of 65. The contribution from the State required to bring the scheme into operation at once was capitalised at £750,000,000. Reduction of income-tax was proposed, amounting to 6*d.* in the £ on the standard rate, making the rate 4*s.* in the £ instead of 4*s.* 6*d.*

Earned Incomes.

It was also proposed to increase the relief on earned incomes from a deduction of one-tenth, subject to a maximum deduction of £200, to a deduction of one-sixth, subject to a maximum deduction of £250. It was proposed to regard as earned income investment income of taxpayers whose age was 65 years or more and whose total income did not exceed £500. In the case of married persons this relief will be granted when either spouse was of the age stated.

HOUSE OF COMMONS.

TUESDAY, APRIL 28TH.

Medical Examinations of Pensioners.

Mr. W. C. ROBINSON asked the Minister of Pensions how many medical boards were held in the 12 months ending March 31st, 1925; in how many cases were final awards of life pensions issued; in how many cases were final awards given of final weekly allowances; and what was the average period of same.—Lieut.-Colonel G. F. STANLEY (Parliamentary Secretary to the Ministry of Peusions) replied: During the period referred to 288,000 medical examinations were held by the Ministry. During the same period 48,500 final awards of 20 per cent. assessment and over, and 16,000 final awards of final weekly allowances of an average duration of 104 weeks, were notified.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MEETINGS OF SECTIONS.

Monday, May 4th.

SOCIAL EVENING: at 8.30 P.M.

At 8.30 P.M., Fellows, Members of Sections, and their friends will be received by the President, Sir StClair Thomson.

At 9.30 P.M., Dr. Robert Hutchison will give an address on Dr. Samuel Johnson and Medicine (illustrated with eighteenth century portraits).

The Library will be open, and various objects of interest will be exhibited. Music, light refreshments, and cigarettes.

Tuesday, May 5th.

ORTHOPÆDICS: at 5.30 P.M. (Cases at 5 P.M.)
Annual General Meeting:
Election of Officers and Council.

Wednesday, May 6th.

SURGERY: at 8.30 P.M.
Annual General Meeting:
Election of Officers and Council.
Informal Discussion on
Acute Obstruction of the Small Intestine.

Thursday, May 7th.

OBSTETRICS AND GYNÆCOLOGY: at 6 P.M.
Annual General Meeting.

Friday, May 8th.

CLINICAL: at 5.30 P.M. (Cases at 5 P.M.)
Annual General Meeting:
Election of Officers and Council for 1925-26.

OPHTHALMOLOGY / COMPARATIVE MEDICINE } at 8.30 P.M. (Cases at 8 P.M.)
Discussion on
Diseases of the Eyes Common to Man and Animals.
Openers:
Mr. Humphrey Neame: Parenchymatous Keratitis in Animals.
Mr. Henry Gray: Ulcerative Affections of the Cornea, their Complications and Sequelæ.
Mr. A. F. MacCallan and Mr. Herbert Mason: Cataract in Horses with some Reference to Iritis.

ROYAL INSTITUTION, 21, Albemarle-street, W.
Tuesday, May 5th.—5.15 P.M., Prof. J. Barcroft: Effects of Climate on the Circulation (III.).
Friday.—9 P.M., Dr. H. H. Dale: Circulation of Blood in the Capillary Vessels.

RONTGEN SOCIETY, British Institute of Radiology, 32, Welbeck-street, W.
Tuesday, May 5th.—8.15 P.M., Mr. C. H. Holbeach, A.M.I.E.E.: Paper on Some further Aspects of the Theory and Operation of Potter-Bucky Diaphragms, and a Note on the Treatment of Coolidge Tubes.

MANCHESTER MEDICAL SOCIETY, University of Manchester.
Wednesday, May 6th.—8 P.M., Dr. A. E. Barclay: Play and a Little Work in Canada and the States.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS, Pall Mall East, S.W.
Tuesday, May 5th.—5 P.M., Dr. E. D. Adrian: The Interpretation of the Electromyogram. (First Oliver-Sharpey Lecture.)
Thursday.—5 P.M. (Second Oliver-Sharpey Lecture.)

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.
Hampstead General Hospital, Haverstock Hill, N.W. Intensive Course in Medicine, Surgery, and the Special Departments from 10.30 to 5.30 P.M. daily (second week, as per syllabus).—Queen's Hospital for Children, Hackney-road, Bethnal Green, E. Special Course in Diseases of Children. Morning and afternoon sessions (second week).—St. Mark's Hospital, City-road, E.C. Special Course in Proctology. Lectures, Demonstrations, and Operations each afternoon (second week).

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C. 1.

POST-GRADUATE COURSE: May–June.

Clinical Lectures and Demonstrations.

Monday, May 4th.—2 P.M., Out-patient Clinic: Dr. Hinds Howell. 3.30 P.M., Syphilis of the Nervous System: Dr. Adie.
Tuesday, May 5th.—2 P.M., Out-patient Clinic: Dr. Walshe. 3.30 P.M., Subacute Combined Degeneration and Allied Disorders: Dr. Birley.
Thursday, May 7th.—2 P.M., Out-patient Clinic: Dr. Kinnier Wilson. 3.30 P.M., Paths of Intracranial Infection in Otitis Media: Mr. Theodore Just.
Friday, May 8th.—2 P.M., Out-patient Clinic: Dr. Gordon Holmes. 3.30 P.M., Demonstrations of Re-educational Methods in Exercise Room: Mr. Elmquist.
Full particulars on application to
J. G. Greenfield, Dean of Medical School.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.
Monday, May 4th.—11 A.M., Surgical Registrar: Surgical Wards. 12 noon, Mr. Simmonds: Applied Anatomy. 2 P.M., Mr. Bishop Harman: Eye Dept.
Tuesday.—10 A.M., Medical Registrar: Clinical Methods. 12 noon, Dr. Burrell: Chest Cases. 2 P.M., Mr. Sinclair: Surgical Out-patients.
Wednesday.—2 P.M., Dr. Burnford: Medical Wards. 2 P.M., Mr. Tyrrell Gray: Operations. 2.30 P.M., Mr. Donald Armour: Surgical Wards.
Thursday.—10 A.M., Dr. Grainger Stewart: Neurological Dept. 11 A.M., Sir Henry Simson: Gynæcological Wards. 12 noon, Dr. Pritchard: Modern Methods in Medicine.
Friday.—12 noon, Surgical Registrar: Surgical Pathology. 2 P.M., Mr. Vlasto: Throat, Nose, and Ear Dept. 3 P.M., Dr. Pritchard: Medical Wards.
Saturday.—10 A.M., Dr. Saunders: Medical Diseases of Children. 10 A.M., Mr. Banks-Davis: Operations on Throat, Nose, and Ear.
Daily, 10 A.M. to 6 P.M., Saturdays, 10 A.M. to 1 P.M., In-patients, Out-patients, Operations, Special Departments.

UNIVERSITY COLLEGE HOSPITAL.
Monday, May 4th.—5.30 P.M., Prof. A. V. Hill: The Physical Environment of the Living Cell.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.
Thursday, May 7th.—4 P.M., Dr. Cockayne: Some Urinary Disorders in Children.

INSTITUTE OF PATHOLOGY AND RESEARCH, ST. MARY'S HOSPITAL.
Thursday, May 7th.—5 P.M., Prof. W. E. Dixon: Cerebrospinal Fluid with Special Reference to Pituitary Secretion.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, Leicester-square, W.C.
Tuesday, May 5th.—5 P.M., Dr. Sibley: Electro-Therapeutics.
Thursday.—5 P.M., Dr. Barber: Alopecia Areata and Vitiligo.

UNIVERSITY OF LIVERPOOL POST-GRADUATE LECTURES. (At 3.30 P.M.)
Tuesday, May 5th.—(At the Southern Hospital.) Mr. H. Taylor: Functional Paralyses after Minor Injuries of the Limbs.
Wednesday.—(At the Northern Hospital.) Dr. L. Cunningham: Jaundice.
Friday.—(At the Royal Infirmary.) Dr. John Hay: Raised Blood Pressure.

MANCHESTER ROYAL INFIRMARY.
Tuesday, May 5th.—4.15 P.M., Dr. W. Fletcher Shaw: Sterility.
Friday.—4.15 P.M., Dr. C. H. Melland and Mr. W. R. Douglas: Demonstration of Cases.

Appointments.

Hall, Percy, L.R.C.P. Lond., M.R.C.S., has been appointed Honorary Actino-therapist to the Mount Vernon Hospital, Northwood.

Hunt, E. Rivaz, M.D. Camb., M.R.C.P. Lond., Honorary Physician to the Royal Sussex County Hospital, Brighton.

Ross-Keyt, F. D., M.B., Ch.B. Aberd., Assistant Medical Officer of Health of Chester.

Thornley, Edith I., M.B., Ch.B. Glasg., Assistant School Medical Officer, West Riding County Council.

Certifying Surgeons under the Factory and Workshop Acts: Pratt, F. Y., M.D. Dub. (Horncastle), Terry, R. H., L.S.A., L.M.S.S.A. Lond. (Nelson, Glamorgan), Douglas, W. R., M.B., Ch.B. Manch., F.R.C.S. Eng., an additional Medical Referee under the Workmen's Compensation Act, 1906, for Circuit No. 10, for the purpose of dealing with surgical cases of exceptional difficulty arising in those Districts.

Vacancies.

For further information refer to the advertisement columns.

Bath, Royal United Hospital.—Asst. H.S. £120.
Bedford County Hospital.—Asst. H.S. £130.
Birmingham and Midland Homœopathic Hospital and Dispensary.—Res. H.S. £175.
Brighton, Royal Sussex County Hospital.—Hon. Med. Clin. Asst.
Cambridgeshire Tuberculosis Colony.—H.P. at rate of £100.
Carmarthen, Joint Counties Mental Hospital.—Asst. M.O. at rate of £350.
City of London Hospital for Dis. of the Heart, &c., Victoria Park, E.—H.P. at rate of £100.
Coventry and Warwickshire Hospital, Coventry.—Two Hon. Asst. S.'s.
Dreadnought Hospital, Greenwich.—Anæsthetist. 50 guineas.
Durham County Council, Education Dept.—Asst. School Oculist, £600. Also Asst. School M.O. £600,

Eastbourne, Princess Alice Hospital.—Res. H.S. at rate of £175.
Gloucestershire Royal Infirmary and Eye Institution.—Asst. S.
Harefield, Middlesex, County Tuberculosis Sanatorium.—Third Asst. Res. M.O. £400.
Hospital for Epilepsy and Paralysis, Maida Vale, W.—Hon. Asst. P.
Leicester City Education Committee.—Asst. Sch. M.O. £600.
London County Council Mental Hospitals.—Eighth Asst. M.O. £440.
London Homœopathic Hospital, Great Ormond-street, W.C.—Two Anæsthetists. Each £50.
Manchester Royal Infirmary.—Res. Surg. O. £200. Also Surg. Reg. £150.
Metropolitan Hospital, Kingsland-road, N.—Surg. for Diseases of Women.
Mexborough, Montagu Hospital.—Hon. Visiting and Consulting Surgeons.
Middlesex Hospital, W.—P. and Asst. P.
Nottingham General Dispensary.—Res. Surg. £200.
Queen's Hospital for Children, Hackney-road, Bethnal Green, E.—Asst. S.
Richmond, Surrey, Royal Hospital.—Asst. H.S. £100.
Royal Northern Hospital, Holloway, N.—H.S., Joint H.P. and H.S. Each at rate of £70, and Cas. O. at rate of £90. Also P., Dent. Surg., and Asst. Dent. S.
Royal Society of Medicine, 1, Wimpole-street, W.—Secretary. £800.
Ruthin Castle (Duff House), North Wales.—Jun. Res. P. £150.
St. Mary's Hospital for Women and Children, Plaistow, E.—Res. M.O. and Asst. Res. M.O. at rate of £175 and £130 respectively.
Salford Royal Hospital.—Hon. P. and Hon. S.
Sheffield Royal Infirmary.—H.P. £80.
Southampton Free Eye Hospital.—H.S. £150.
Stoke-on-Trent County Borough.—Asst. M.O. £500.
Walthamstow, Wanstead, and Leyton Children's and General Hospital.—Jun. Res. H.S. £100.
West Middlesex Hospital, Isleworth.—Asst. Med. Supt. £200.
Winchester, Hampshire County Council.—Asst. M.O.H. £600.

The Chief Inspector of Factories, Home Office, London, S.W., announces the following vacant appointments: Tunbridge Wells, Kent; and Kidsgrove, Staffs.

Owing to the resignation of Sir Hamilton Ballance, as one of the Medical Referees under the Workmen's Compensation Act, 1906, for the Districts of the Aylsham, Downham Market, East Dereham, Fakenham, Holt, King's Lynn, North Walsham, Norwich, Swaffham, Thetford, and Wymondham County Courts, there is a vacancy for a surgeon to fill the post. Applications should reach the Private Secretary Home Office, not later than May 16th.

Births, Marriages, and Deaths.

BIRTHS.

CONLEY.—On April 24th, at Almora, Stockton-road, West Hartlepool, the wife of Dr. Wallace M. Conley, of a son.

GRIFFITH.—On April 19th, at Brunswick-square, Hove, the wife of John R. Griffith, F.R.C.S., of a daughter.

WHITBY.—On April 26th, the wife of L. E. H. Whitby, M.B., B.Ch., of Cavendish-mansions, West Hampstead, of a son.

MARRIAGES.

CHILD—YORKE.—On April 23rd, at St. Peter's, Slinfold, Stanley Child, M.A., M.B., D.P.H., to Phyllis Braybrooke, second daughter of Mr. C. F. Yorke, of Hall Land, Slinfold.

GIBB—MUIR.—On April 21st, at Cadzow Parish Church, James Gibb, M.A., M.B., Ch.B., Sandfield House Downham Market, Norfolk, to Janie Gilmour ("Robin"), younger daughter of Mr. and Mrs. Robert Muir, Portland Park, Hamilton, Lanarkshire.

HARPER—HARGOOD-ASH.—On April 23rd, at St. Peter's, Cranley-gardens, John Maurice Harper, V.D., M.R.C.S., D.P.H., Grosvenor-place, Bath, to Caroline Mary St. Albyn, eldest daughter of the late Mr. W. C. Hargood-Ash, of Portmore, Weymouth, and Mrs. Hargood-Ash, of Ashton, Park-gardens, Bath.

SMITH—THOMS.—On March 24th, 1925, at St. Andrew's Church, Calcutta, James Ironside Smith, I.C.S., Waltair, Vizagapatam District, Madras, to Amy Macdougall Thoms, M.D., M.R.C.P., late of Broughty Ferry, Dundee.

WAYTE—YOUNG.—On April 25th, at the Parish Church, Croydon, John Woollaston Wayte, M.C., M.B., B.S. Lond., to Dorothy Hay Young, youngest daughter of George Hay Young, of "Lonsdale," Campden-road, South Croydon.

DEATHS.

HAMILTON.—On April 26th, at "Accra," St. Mark's-hill, Surbiton, suddenly, of heart failure, Lieut.-Colonel Hamilton, late R.A.M.C. and R.A.F., M.D., M.R.C.S., L.R.C.P.

MCFARLAND.—On April 23rd, at Leinster-gardens, W., Armar John McFarland, B.A., M.D., D.P.H., aged 59.

MATHESON.—On April 19th, suddenly, at Duntulm, North Berwick, Angus Matheson, M.D.

MAY.—On April 20th, at Tremeer, St. Tudy, Cornwall, Surgeon Vice-Admiral Sir Arthur May, K.C.B., K.H.P., D.L., aged 70.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

THE AUDIOMETER AND ITS APPLICATION TO MEDICAL RESEARCH.

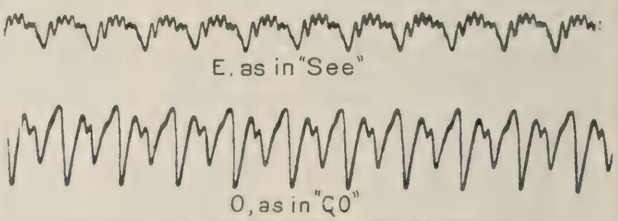
BY C. M. R. BALBI,
ASSOC. M. INST. E.E.

THE term "audiometer" has been recently introduced, as the result of certain new discoveries in aural physics, to define an instrument for the quantitative measurement of hearing. It is believed that the instrument will be of great assistance to the otologist especially in the case of research work on various forms of deafness, as by its means the effect of drugs may be recorded graphically instead of having to rely on the statements made by patients.

The Theory of Audition.

Audiometric measurement involves certain fundamental laws in physics, which must be understood before the audiometer and its method of operation can be explained.

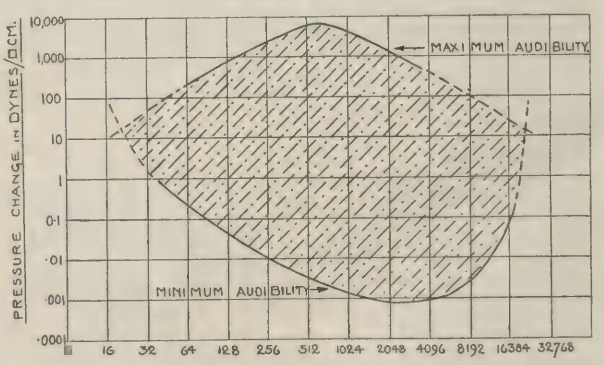
FIG. 1.



Oscillograms of vowel sounds. "O" and "E."

Of first importance are considerations of the character of sound. Sound is said to have (1) frequency; (2) amplitude; and (3) timbre. The term frequency is applied to the fundamental period of any sustained sound. Amplitude may be regarded as the difference in pressure in dynes per sq. cm. between the compressions and rarefactions as they strike tympanum. Timbre refers to the number of overtones or harmonics and their respective amplitudes that are combined in a fundamental. Timbre is of great importance in speech, as by its means characteristic sounds are recognised. The accompanying oscillograms of the sounds "O" and "E" (Fig. 1) illustrate the extent the harmonics preside in the fundamental. In view of the innumerable combination of tones that may be made within the audible range, audiometric measurement would not have been possible if J. B. J. Fourier (a well-known mathematician) had not proved that all periodic wave forms could be analysed into a fundamental and harmonics of a sinusoidal order. This means that for the purpose of audiometric measurement all sounds may be considered as pure tones of different frequencies and amplitudes, so that a complete analysis may be obtained by taking a relation between amplitude and frequency and omitting the question of timbre, and thereby reducing the complication of the problem to a practical level.

FIG. 2.



Frequency in Cycles/Sec.

Audition area for the "standard" ear.

It is known that the human ear is an organ capable of detecting vibrations in the atmosphere, within a frequency spectrum of about 20 to 20,000 cycles per second; outside this region no sound can be heard except that at the lower end of the scale the muscles of the ear produce a sensation which is akin to feeling, but which is quite distinct from hearing. It is also known that intensity plays a part in audibility. The lower limit of audibility is well known to us, but there is also an upper limit which, although not so commonly met with, is quite distinct. It is a point where the intensity is so great as to produce pain.

FIG. 3, A.

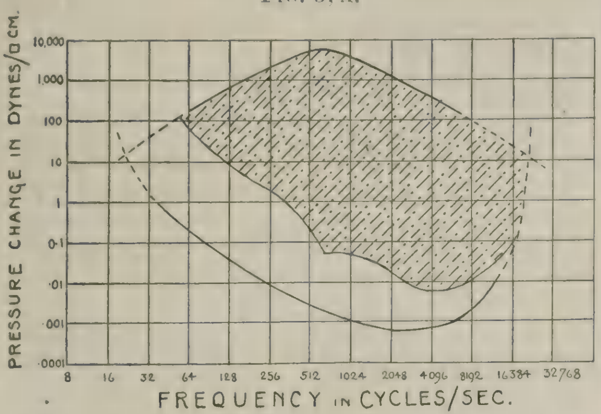


FIG. 3, B.

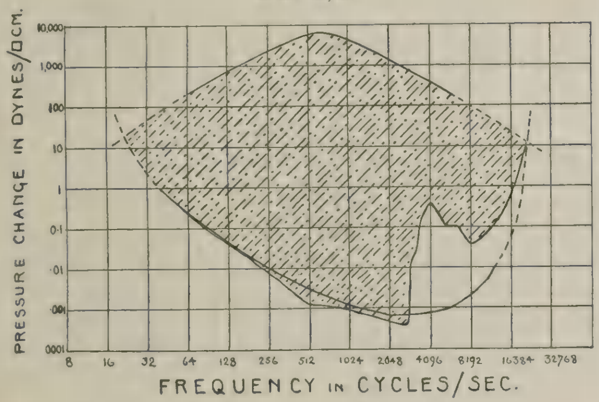

Certain American observers, amongst others Dr. H. Fletcher and E. C. Wente, have shown that there is a general relation for "hearing" between amplitude and frequency for a normal ear. By taking a number of normal cases by audiometric methods Dr. R. L. Wegel showed for the first time[1] what has now been termed the audition area for the standard ear, which depicts in graphical form the region of hearing in coördinates of intensity and frequency (see Fig. 2). Any form of deafness must be shown by a diminution of the area set out for the person with normal hearing.

The Apparatus Described.

From the considerations just given it can be seen that an audiometer must consist of an instrument that is capable of producing sound waves of variable frequency and amplitude. It had been found that the most suitable instrument for producing these effects is one in which the source is electrical, and which converts its energy into sound waves by means of a special form of receiver. The electrical source itself may be of any form, such as a Vreeland oscillator or special alternator, but as it is most important that it shall be absolutely free from harmonics at all frequencies and loads, it is found desirable to use a valve oscillator. The control of the two variable factors required calls for careful consideration. The control of frequency may be carried out by varying the ratio of a capacity and inductance in a tuned circuit. A set of 16 frequencies covering about eight octaves are found quite sufficient to cover the requirements of any test. The control of intensity may be carried out by varying the input and measuring its degree, or the input may be kept constant and the output varied by means of a resistance or attenuator. The calibration of the instrument somewhat depends on the scales that have been chosen for frequency and intensity. In the audition chart for the standard ear obtained by Dr. Wegel, the scale of both ordinates is made logarithmic.

It is easy to see why this should be so in the case of frequency, as our musical scale is logarithmic; it is found from experience that the intensity scale should also be logarithmic, as this gives the most practical shape to the audition area for the purpose of diagnosis. Frequency can be checked by the simple method of testing the intervals that have been adopted against a set of standard tuning-forks, while in the case of intensity we must either take readings and find their logarithms or employ a direct reading method such as the attenuator. In either case the intensity must bear strict relation to the results obtained for the standard audition area of a normal ear.

FIG. 3, C.

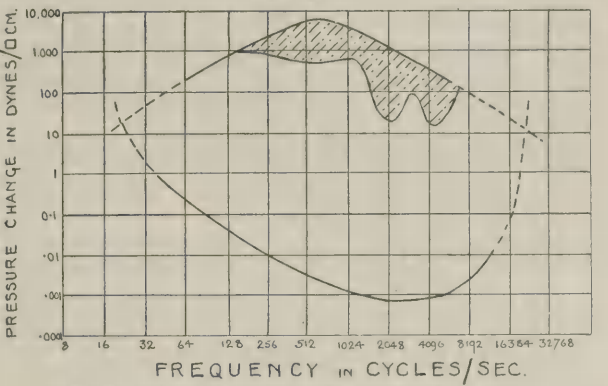

FIG. 3, A, B, C.—Examples of abnormal hearing.

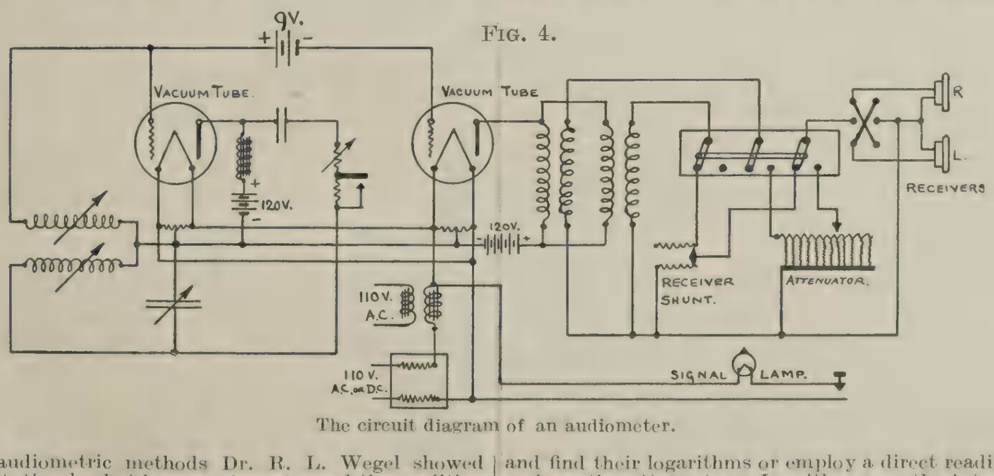
FIG. 4.



The circuit diagram of an audiometer.

A special form of receiver has to be employed in connexion with audiometric measurements. Its function is to convert the electrical energy produced into sound waves so that the response is proportional to the electrical input at all frequencies; this means that the receiver must be entirely free from resonance. This end may be achieved by special air damping or by the method invented by Mr. J. T. Irwin,[2] in which a special form of electrical damping is employed; this is found to be a much more reliable arrangement.

---

[1] The Physical Review, N.S., vol. xix., No. 6, June, 1922. Proceedings of the National Academy of Sciences, vol. viii., No. 7, July, 1922.

Method of Testing.

The audiometer is simple in its operation. A complete test may be carried out in about ten minutes, and only minimum audibility is required. Each ear is tested separately and the test is commenced by the patient holding the special receiver to his ears. Absolute silence must be maintained through the test, and all conversation avoided. The patient is provided with a "push button" for controlling a small electric lamp which he is told to operate directly he fails to hear any sound in the receiver after the test has begun. The oscillating circuit is now set to a particular frequency and the intensity varied slowly; the operator watches the patient's signals to determine the critical point and then takes a reading. This process is repeated about every half octave for eight octaves and the results plotted on a chart. A number of these charts are shown in Fig. 3, A, B, C, taken from actual test figures. The accuracy of the apparatus is sufficient to show up any small change in a patient's hearing, so that quantitative results can be obtained.

These results were obtained by an apparatus made by the Western Electric Co., a circuit diagram of which is shown in Fig. 4.

VOCATIONAL TRAINING OF HIGH-GRADE MENTAL DEFECTIVES.

The problem of the mentally defective child must always present itself under two aspects. On the one hand, there is the case where the structural defect in the central nervous system is so gross that there can be no hope of turning the individual into a competent member of modern society; he can only be protected from the stress of life in some custodial institution for the whole period of his days. On the other hand, there is the higher grade of mental defect where careful guidance and skilled attention during the difficult years of childhood and adolescence may result in the production of a useful member of the community from material which, under less sheltered circumstances, would undoubtedly have turned into the defective or the criminal. This group includes many "borderline" cases of temperamental inadequacy as well as the more typical intellectual inefficiency revealed by "intelligence tests," and it is steadily increasing in size owing to the growth of knowledge as to its diagnosis and treatment. The Besford Court Catholic Mental Welfare Hospital is among the many institutions, originally founded as an asylum for the first class of child, which are now steadily directing their attention towards the selection and salvation of the second class. The seventh annual report of its resident manager is a treatise *in parvo* on mental defect and the name of the institution reveals the nature of the work undertaken. "Mental welfare" is the keynote of the hospital, and only such children are accepted as provide reasonable hope of becoming capable of return to ordinary life between the ages of 16 and 21. No social differentiation is made; cases sent by the mental deficiency and education committees and by the board of guardians are mingled with private cases, and those sent by the Home Office on account of delinquency or inimical home conditions. The spirit is that of a public school, both as regards general education and games. During the last two years an important modification has been put into effect. Whereas originally the hospital was staffed by sisters, whose devotion and zeal produced success where success could hardly have been anticipated by the most confident, yet the importance of masculine influence on growing boys was gradually borne in on those responsible for the institution, so that now it is proposed to divide the home into two departments, a junior for small boys, where the education will be elementary and preponderatingly manual. This will be staffed by the nuns, while the senior department will be under a staff of masters and the training will be a general one culminating in definite vocational classes. The summer camp has been found a most valuable feature of the work; the boys look forward to it with the greatest enthusiasm and return from it in a state of physical fitness which keeps the infirmary almost empty for the rest of the year. It is not a mere holiday camp but a summer school, under canvas, of extraordinary value. The report stresses the mistaken kindness of trying to keep these "misfits" at home in the hope that they will "outgrow" it; when the parents realise that the boy of 15 or 16 is unable to obtain or to keep a job it is too late to do anything for him; had he been placed under suitable care ten years earlier he might have been saved. At Besford Court "a definite stand has been taken against the idea that nothing can be done with the mental defective except feed him and house him." He is being trained in accordance with his specific aptitudes by persons "animated with real enthusiasm and gifted with unending patience, who are prepared to treat each child as does the solver of a problem in chess, remembering that the problem is always being set anew and that the reactions of to-day may restate the problem of yesterday." It is along such lines that the hope of the future for this difficult social and personal problem must indubitably lie.

THE CORONER OF THE KING'S HOUSEHOLD.

A correspondent inquires as to the meaning of this office. Coroners' jurisdiction, as all know, is very ancient. When it was modernised (v. the Coroners Act of 1887), a few characteristic archaisms survived in the form of local franchises. The two chief franchise coroners are (1) the coroner of the Admiralty, who is, in fact, the President of the Admiralty Division of the High Court. He has jurisdiction over deaths at sea and a concurrent jurisdiction with the local county coroner over deaths in big ships on arms of the sea or estuaries; in exercising these concurrent duties the coroner under whose jurisdiction the body first comes holds the inquest. (2) The coroner of the King's household is the other important franchise coroner. He holds inquests on bodies lying in the King's palaces or in the curtilage of any house where the King is temporarily resident. The Lord Steward appoints this officer and the jury consists of officers of the household.

A DIRECTORY OF WELFARE CENTRES.

The Ministry of Health has just reissued the List of Maternity and Child Welfare Centres in England (List 2, M. and C. W. 9, H.M. Stationery Office, pp. 102, price 1*s.* 6*d.*), which contains the addresses of all municipal and voluntary centres known to the Ministry in March, 1925. It is divided into three sections, London, county boroughs, and counties, in the last named the centres being classified under the sanitary districts in which they are situated. The centres are specially marked at which antenatal consultations are given. At about 400 centres special arrangements are made for dental treatment. The chief function of these centres is stated to be "to prevent avoidable sickness and injury among women and children, by means of systematic medical and nursing supervision and instruction in hygiene and a healthy mode of living." Patients needing treatment other than for minor ailments, it is added, should, as a rule, be referred to a doctor or a hospital. The actual number of centres included in the list is 2112, 519 being conducted by county councils, 837 by local sanitary authorities, and 756 by voluntary societies.

IS EVERY CASE OF TYPHOID AN ACCIDENT?

This heading, which appeared in the *American City* for March, refers to a recent decision in the American law courts. It appears that the Supreme Court of Illinois has affirmed a judgment of the Appellate Court in favour of the estate of the holder of an accident insurance policy who died of typhoid fever. The said holder died as the result of drinking polluted river water admitted by accident to the drinking water pipes of a railroad shop. Two systems of pipes were connected at only one point, where there was a gate valve which kept the water from either system from flowing into the other. The valve connecting the two systems of water being defective, the drinking water was polluted, and the holder of the accident insurance policy, uninformed of this condition, drank several times from the system of pipes supposed to convey only drinking water. The insurance company contended that his death was not caused by "external, violent, and accidental means" for which indemnity was provided, but the Supreme Court held otherwise. This case, an account of which has been published by the New York State Department of Health in its *Health News*, has, of course, caused a flutter in the insurance world. The *Mutual Underwriter* points out that under these conditions accident insurance companies will have to revise their policies and definitely exclude bacterial diseases from the lists of accidents qualifying for compensation. It is argued that it would be as consistent to sue under an accident policy for pneumonia caused by accidentally catching cold and, indeed, to sue for any other disease not contracted intentionally. According to this line of argument, accident policies will have to become life insurance policies, and this would mean that the premiums for accident policies, so-called, would have to be increased considerably. It will be interesting to see if this judgment in the American courts will affect accident insurance in this country.

Croonian Lectures

ON THE

RÔLE OF FATS IN VITAL PHENOMENA.

BY J. B. LEATHES, F.R.C.P. LOND., F.R.S.,
PROFESSOR OF PHYSIOLOGY, UNIVERSITY OF SHEFFIELD.

LECTURE III.*

MYELIN FORMS OF LECITHINE.

THERE is a phenomenon that was described three-quarters of a century ago by Virchow, known to all of us at least from description, and generally referred to as the myelin forms which are exhibited by lecithine and mixtures in which lecithine is present. This phenomenon has been but little studied in recent years, and now that physical chemistry is contributing so much to our understanding of unhomogeneous systems and the colloidal state, it is timely that attention should be turned to it again. It is more than likely that the result will be to throw new light on the physiological importance of fats. It is so long since great expectations were aroused by the recognition of the wide distribution of lecithine in the composition of all forms of life, and so long that their realisation has been waited for in vain, that they are seldom even referred to now. But since through the work of McLean, of Parnas, and of Levene, material of greater purity is comparatively easy to obtain, a revival of interest is to be expected.

I have for many years been in the habit of making with students crude preparations of lecithine from yolk of egg or the brain, a streak of which on a glass slide under a drop of water showed the outgrowth of buds that develop into twisting cylindrical forms like the mycelium of a fungus. But lately with purer preparations, and especially with that given me by Dr. Levene, I have observed these outgrowths more systematically, taking photographs of their appearance after different intervals of time, and using various solutions as well as distilled water. And in order to obtain records that can be compared with each other I have especially made use of photographs taken every half-minute over a period of two hours on kinema film ribbons, which when developed can be projected at a convenient rate, about 10–15 a second. A cavity slide is used, and a minute streak of the waxy material is put in the centre of the cavity, so as to show a well-defined edge under a 2-inch objective. The first photograph of this edge is now taken; then two or three drops of water or some solution are put on so as to fill the depression in the slide, a cover-glass put on, and as quickly as possible, generally about 1½ minutes after contact with the liquid, the series of photographs is started. The magnification used on the film is about 40. On projecting the film an idea is obtained of the nature and activity of the process which is set up on contact with the solution that is very much more reliable and distinct than that which is given by direct observations through the microscope extending in each case over hours.

For showing at these lectures a number of such films was prepared; for presentation in print, from some of these films the first photograph and five at intervals later, the same intervals in each, are reproduced in a group of six from each of the selected films. This is a far less satisfactory way of presenting the changes that develop in the time, but still gives some idea of what the film shows. The six photographs in each group are arranged in order, the first three on the left with the first at the top of the column, and the fourth at the top of the right-hand column.

The first photograph in each group shows the edge of the film before it was moistened; the second the same edge 2½ minutes after being moistened, the third 9 minutes, the fourth 17, the fifth 33, and the sixth 57 minutes. No photograph is reproduced in this series from those taken in the second hour, except two in Fig. 2, to which reference will be made below. In some cases the solution applied set up changes which caused the edge of the streak to move right across the field; when that occurred the slide was moved so as to bring it back to a position that would allow it to be observed for longer.

The series of photographs in Fig. 1 is fairly typical of what occurs when distilled water, recently boiled and cooled, is put on. No intentional movement of the slide was necessary. But it looks as if some slight unintentional movement had occurred between the taking of the fourth and the fifth picture, on referring to the film about 20 minutes from the beginning of the experiment. At the time when this film was taken it had not been discovered that some vibration was transmitted to the concrete floor where the microscope and camera were set up when a motor was running in another room a little distance away. The later films were taken only when the motor was not in use. But the error introduced in this case is not material for the purpose, and from experience in many similar experiments with simple water may safely be said to be only slight. The character of the protruding outgrowths, the rate at which they appear, and even allowing for the probability of a slight movement of the slide, the rate at which the edge advances across the field is typical for pure water, when compared with the rates observed with some of the solutions to be referred to later.

Fig. 2 shows the effect of putting on dilute ammonia (N/100) instead of distilled water. The second picture, only 2½ minutes after the ammonia was put on, shows that the budding protrusions had reached a distance 8 mm. (= 0·2 mm. unmagnified) from the original position. It had advanced to the edge of the field in 22 minutes, 5 minutes after the fourth picture, in absolute measurement about 0·5 mm. In the course of two hours, during which the slide was moved three times to keep the edge in view, the total advance was about 1·2 mm.; the fifth and sixth pictures in this figure were taken later than in the case of the other figures, 15 minutes apart near the end of the second hour. They show swollen bubble-like formations at this stage and the curious concentric wrinkles in the surface which are very common with some solutions. No photographs are reproduced from the films taken with sodium and potassium hydrates in the same concentration as the ammonia, N/100. They show similar forms, similar markings on the surface of the globular outgrowths, and similar (though not quite so rapid) rates of growth and movement, to those shown by the action of ammonia.

Fig. 3 shows an effect very different from those given by these three bases, when lime-water is used in the same strength. The edge of the preparation remains perfectly sharply defined throughout the experiment, and in fact for as long as it is observed: there is no indication of buds or protrusions. There is a zone at the edge more transparent than the centre, which to the naked eye looks chalky and opaque. But all the free budding outgrowth of myelin forms is stopped.

The natural suggestion occurs here that this difference between the action of calcium hydrate and the hydrates of ammonium, potassium, and sodium would be shown too if baryta were substituted for lime-water. But the film taken with baryta water, N/100, from which the photographs in Fig. 4 are reproduced, shows that baryta does not give the same result; the edge of the lecithine streak advances and is broken up by the formation and detachment of globular masses. It looks, therefore, as if the action of calcium was something peculiar to this ion and not shared in common with other dibasic cations. (Cf. too Fig. 16 below.)

---

* Lectures I. and II. appeared in THE LANCET of April 18th and 25th respectively. Lecture IV. will appear in a subsequent issue.

Figs. 5, 6 and 7 are from films taken to show the effect of acids, hydrochloric, sulphuric, and acetic, each in N/100 strength. They resemble one another in the freedom and rapidity with which cylindrical outgrowths are formed, though Fig. 5, where the acid was hydrochloric, shows this difference as compared with the action of water alone in much the most marked degree. The region of contact with the acid in this case when the film is projected shows the most astonishing liveliness; the writhing movements of the coiled cylindrical processes can perhaps be imagined even from the isolated photographs. The slide had to be moved twice in the first hour and the advancing edge was even so off the field from the thirty-first to the sixty-fifth photograph, for 17 minutes, that is to say; having travelled at one point 0·5 mm., 20 mm. in the photograph, in 16 minutes. The fact that the action of sulphuric acid, though generally similar, has never been seen to produce such activity as hydrochloric acid suggests that, since the hydrogen ion was present in about the same concentration in these two cases, the effect is in part due to the properties of the anion as well. Acetic acid produces a less vigorous action than the other two acids.

FIG. 1.

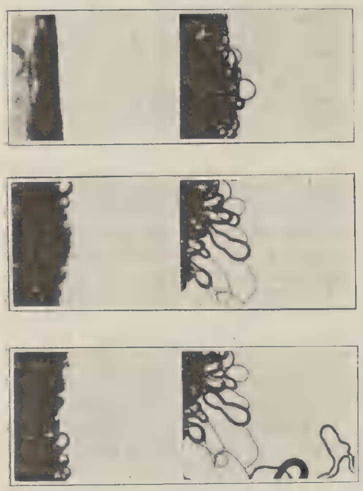

FIG. 2.

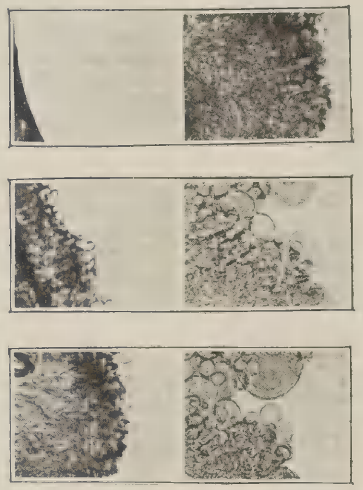

FIG. 3.

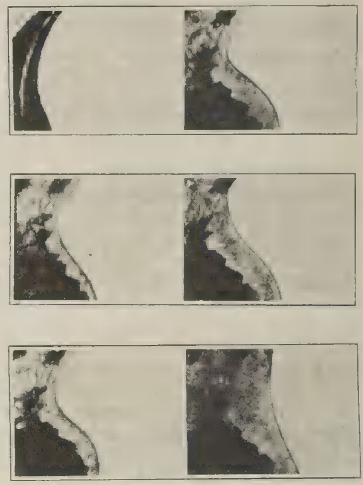

FIG. 4.

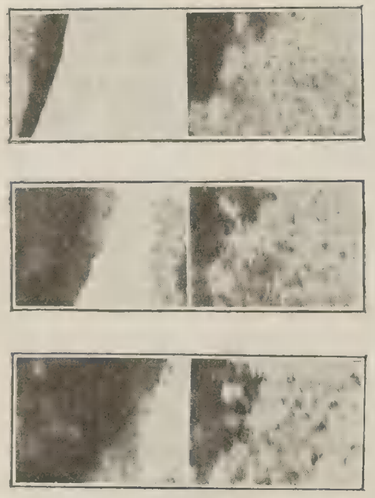

FIG. 5.

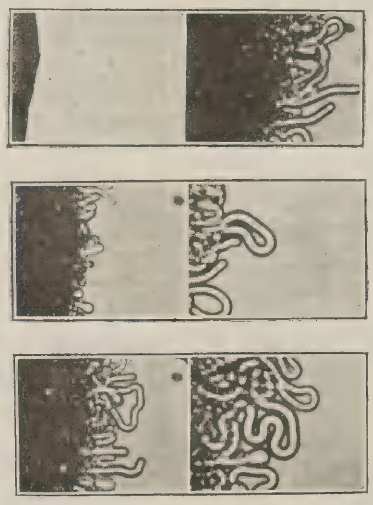

FIG. 6.

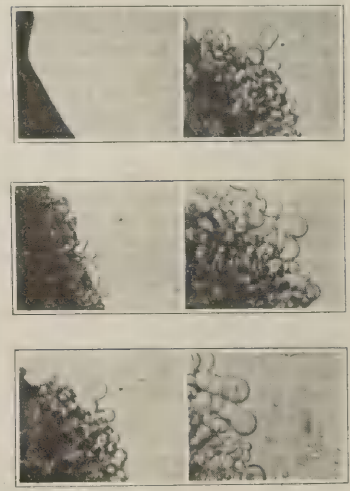

The three next figures, Nos. 8, 9, and 10, are from films taken to show the influence of concentrated solutions of the salts ammonium sulphate, sodium chloride, and calcium chloride. The solutions which were saturated in each case were brought to a neutral reaction (pH 6·6 in the case of the first and last, 7·1 in the case of the sodium chloride). This series was suggested by the way in which the lecithine streak in some of the solutions grew and spread out. Without for the moment discussing the nature of the whole phenomenon, it seemed clear that it must involve the incorporation of water in the lecithine; and it was of interest to see how far this was interfered with by a high osmotic pressure in the fluid. It may appear surprising that neither the swelling of the mass nor the outgrowth of buds and protrusions from the surface was entirely stopped either by saturated ammonium sulphate or by saturated sodium chloride solution. The budding from the surface is with both solutions distinct in the first ten minutes, though it proceeds slowly afterwards; and the same may be said with regard to the swelling. It is almost inconceivable that this involves the extraction of water from solutions of such concentration, and yet it is not easy to suppose that in the process of imbibition other molecules are as readily taken up as those of water. Clearly they are not taken up as readily;

the question is whether they are taken up at all, and at any rate at first sight it appears as if they must be; but whether their presence does anything more than embarrass the action of the water, and whether such effect as is produced is produced by the water in spite of its companions it is at present impossible to say.

FIG. 7.

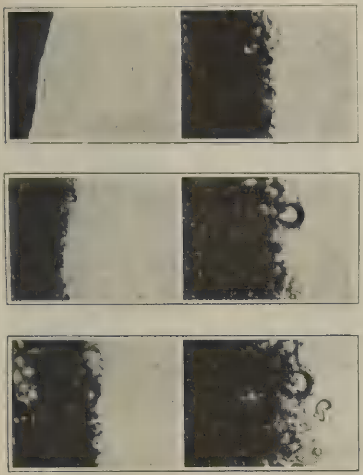

FIG. 8.

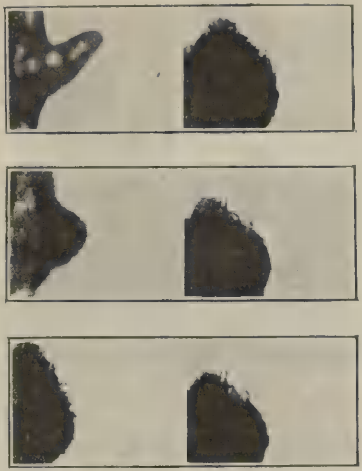

FIG. 9.

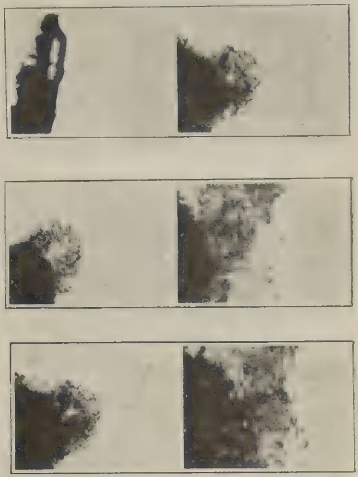

But one thing is obvious: in Fig. 10 the action of calcium chloride in high concentration is very different from that of the other salts to which reference has been made. There is no budding of myelin forms: a semi-transparent border appears at the edge of the lecithine after nearly half an hour, and apart from this there is hardly any indication of swelling. It looks as if something was freezing up the action that otherwise so constantly occurs between lecithine and water with which it is in contact, much as is the case with calcium hydrate, as shown in Fig. 3.

Two other groups of photographs are shown in Figs. 11 and 12, which are meant to lead to another line of thought. That lecithine is insoluble in water is proved by the fact that it gives a permanent monomolecular film on water and dilute acids. There must be an interface, therefore, where water and lecithine meet, and substances which concentrate at the water surface may be expected to appear at this interface: it is of interest to see what is the effect on the behaviour of lecithine when this happens.

FIG. 10.

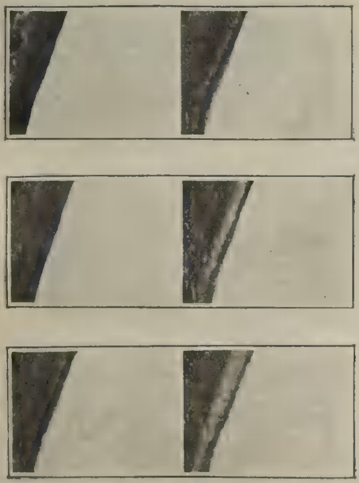

FIG. 11.

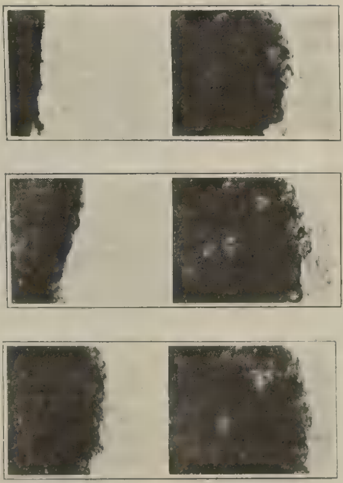

FIG. 12.

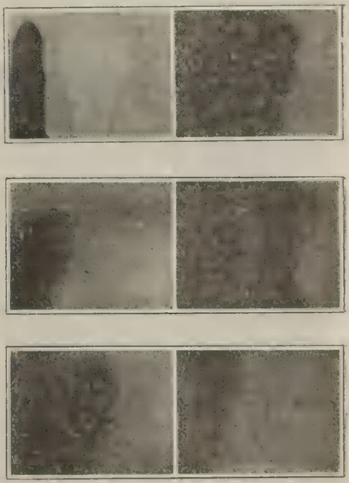

In Fig. 11 the fluid put on the slide was egg white filtered and diluted with about four volumes of a sodium phosphate solution so as to contain about 2½ per cent. of albumin and have a neutral reaction (pH 7·2). The fact that the phosphate solution allows the budding process to go on freely and unhindered can be seen from the final result, after a much longer period for action it is true, which is shown in Fig. 17 below. So it is clear that the fact that the budding process is very much restrained by the solution here used must be ascribed to the egg white which it contained and not to the phosphate. In comparison with water alone (Fig. 1) the myelin forms are here very modest though not entirely suppressed. The solid film of egg-albumin which Ramsden has shown to be formed at the surface of its solutions appears to be formed at the surface in contact with the lecithine and to restrain the profuse growth of myelin buds without altogether arresting their formation in spite of its solidity. It is certainly permeable to water in any case: just as the skin on heated milk formed in the first instance in the same way thickens and becomes conspicuous only when evaporation through it causes it to thicken. The lecithine swells and takes up water through the albumin film very noticeably. Two other films were prepared, photographs from which are not here reproduced, in which solutions containing the same concentration of egg white, but in addition a slight excess of hydrochloric acid in the one case and of ammonium hydrate in the other: these showed that the exuberant action of the acid and the ammonia (Figs. 5 and 2) were still more conspicuously restrained. They serve therefore to confirm the account given here of the action of egg white in repressing but not altogether arresting the phenomenon that we are studying.

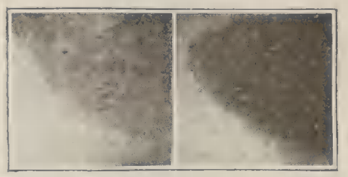
Water. Ammonia.



Potash. Soda.

Fig. 14.

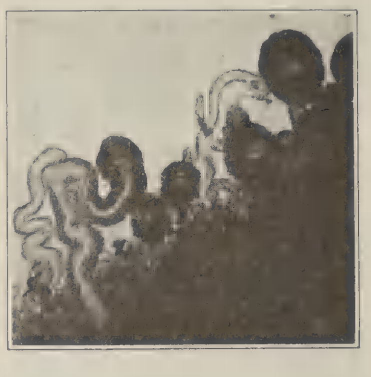


Fig. 15.

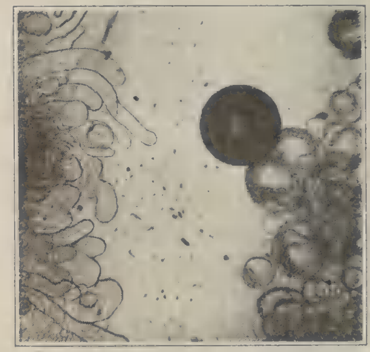

In Fig. 12 are six photographs taken at the same intervals of time as those in the earlier figures though not selected from a continuous series of 240 that go to each of the kinema films. They are, however, comparable with those as they are presented here. The solution here was one of saponin in water (1 in 2000; pH about 4). The effect of the film of saponin concentrated at the interface seems to be very similar to that of egg white.

Theory of Formation of Myelin Forms of Lecithine.

The study of myelin forms in lecithine which I have attempted to sketch in with the help of the kinema projector rests upon a hypothesis regarding the way in which they arise, which may or may not be capable of proof but is this. Lecithine is a fat containing two fatty acid radicals instead of three, one of them certainly unsaturated, the other probably saturated; in place of the third there is phosphoric acid condensed by one of its hydroxyl groups with the glycerol and by a second with a basic alcohol choline, the third hydroxyl group being free. And it behaves when spread in a monomolecular film on water as a fat, at any rate as a fat containing unsaturated acid radicals. The artificially saturated derivative, hydrolecithine, behaves as a saturated fat except that the substitution for the third fatty acid chain, with its paraffin properties, of the group containing phosphoric acid and choline, with affinities for water in both the free acid hydroxyl group and the free basic one, causes the two fatty acid chains to be assigned an area in the film nearly as great as that taken up by the three in tripalmitin: the very high pressure necessary in order to reduce this area shows that the group consisting of glyceryl cholyl phosphoric acid is not readily distorted so as to allow close packing of the fatty acid chains.

But though lecithine is a fat and in a film behaves as one, lecithine in bulk behaves very differently from a fat or oil in contact with water. The "surface-tension" of oil against water is such that the number of molecules of either which are allowed by the attractions of other molecules in their neighbourhood to remain in the surface is kept as small as possible, that is to say, the surface area is kept as small as possible. A drop of oil suspended in water remains spherical. With lecithine it is just the other way. The number of molecules of lecithine in contact with water tends to increase and to become as large as possible; that is why the surface is protruded into the water and the myelin forms appear. The attraction exerted by water on that part of the molecule of lecithine by which it differs from a simple fat is so great, that the molecule is drawn to and held by the water more strongly than it is by the other lecithine molecules in its

Fig. 17.

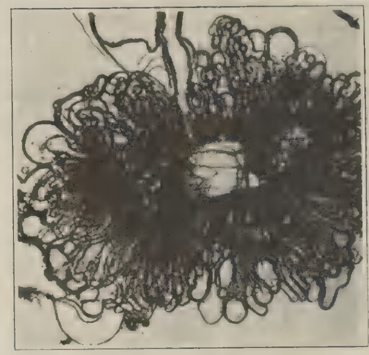

Fig. 18.

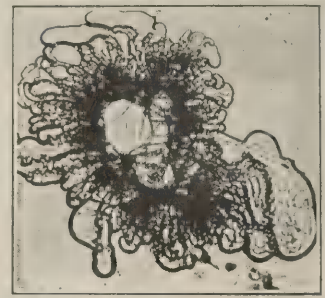

neighbourhood. This attraction prevails over the attractive forces between the paraffin chains, partly because these cannot be packed so close as in a triglyceride. The cohesion between the lecithine molecules is consequently weakened at a water surface, and the surface tends to grow and not to be kept small: if the term surface-tension must be used, the surface-tension is negative.

The conception seems to imply that the attraction of water for the polar group composed of glyceryl cholyl phosphoric acid can make itself felt beyond the first rank of molecules which consists of those actually in contact with the water. According to some the range of molecular attractions is too small for this to be possible. In that case it becomes necessary to suppose that kinetic activity must bring molecules temporarily within range of the action of the water in numbers greater than the average number allowed to remain in the surface; and once within the range such molecules are not then able to escape. It should be remembered, too, that in a monomolecular film of lecithine on water the film is expanded and the molecules are not in close contact with each other. Unsaturated fatty acids and oils also give expanded films, but then in them, in the first place, the simple glyceryl radical is not so strongly bound to the water, and in the second place, the cohesive forces between the fatty acid chains which can be brought closer together are far stronger than those between these chains in lecithine in which they are kept further apart by the large polar group to which they are attached. But however we are to picture it, the number of lecithine molecules in contact with the water tends to grow rapidly and so the myelin forms arise.

FIG. 19.

No. 3. Hæmoglobin, 40 hrs. No. 6. Hæmoglobin, 90 hrs.

FIG. 20.

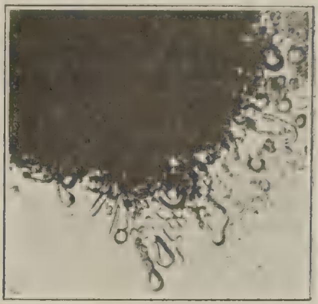

FIG. 21.

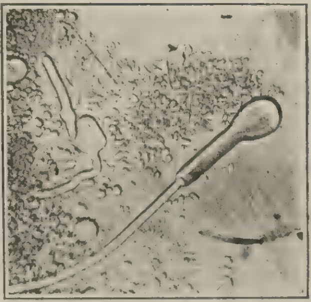

FIG. 22.

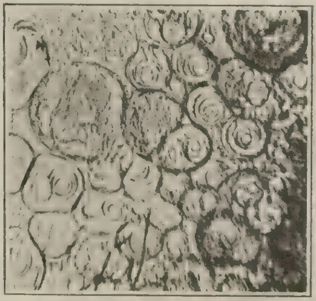


It must be pointed out that hydrolecithine shows no such activity at a water surface, not even when observed on a hot stage heated to 65° C. or more. So that the unsaturated acid chain in lecithine must be retained in order that the phenomenon may be observed. It is this chain, too, that causes lecithine to give an expanded film, while hydrolecithine gives one that is condensed. And yet the presence of the unsaturated paraffin chain is not by itself sufficient to account for the growth of the surface, since oleic acid and olive oil, which give expanded films, do not give myelin forms.

But while the lecithine molecules are pushing out into the water, water molecules are being drawn in among the lecithine. It seems necessary to suppose this because of the growth of the lecithine in volume, because of appearances that suggest alignment of molecules in the lecithine, not only at the external surface but also beneath it within the myelin forms;

and, indeed, the attraction of water and lecithine being reciprocal and the paraffin chains not as close to one another as in a simple glyceride, it seems to follow that water molecules driven by kinetic activity between the lecithine molecules will be detained by their affinity for the group that draws them. Part of the phenomenon then appears to be of the nature of imbibition; imbibition, however, hampered by the long paraffin chains and limited to those regions or strata where the hydrophile groups can congregate.

In two words, therefore, the hypothesis is that myelin forms are due to surface growth and localised imbibition. With this provisional conception of the general nature of the phenomenon, the study outlined above has been directed on three lines: (1) The influence of the presence of various ions in the water; (2) the influence of osmotic pressure; (3) the influence of substances that may be supposed to concentrate at the interface. There remains something to be said under each of these heads and also something on a fourth point, the effect of the presence of cholesterol mixed with or dissolved in the lecithine.

(1) *The Influence of Various Ions.*—In Fig. 13 photographs are shown of the appearance of lecithine 24 hours after being brought into contact with water, with dilute ammonia, and with soda and potash (N/100 in each case). The action of the alkaline fluids differs from that of water in the greater tendency for spherical shapes to arise rather than elongated cylindrical forms; and also in the wrinkled markings parallel to the surface which are seen also in Fig. 2. There and in Fig. 15 these latter were produced in ammonia. In Fig. 13 they show most distinctly in the case of soda, and in Fig. 14 they were also formed under soda. In some cases it looks as if they led to the peeling off of superficial layers or fragments of layers, in others to the formation of spiral clefts.

Such characteristics common to the influence of ammonium, potassium, and sodium hydrates suggests at first that the hydroxyl ion in some way activated and modified the process. But the fact that calcium hydrate has no such effect seems to make a difficulty; while if the action of the alkaline fluids be ascribed to the monobasic cations a difficulty is created by the fact that the dibasic cations—calcium, barium, and strontium—when compared with one another produce different effects. In the left-hand column of Fig. 16 photographs are reproduced of lecithine streaks in weak solutions (N/100) of the hydrates of these three metals. The calcium hydrate was washed in a mortar with three or four changes of water before the solution was prepared. The strontium hydrate was washed by decantation twice: the baryta water prepared from a stronger solution that had been in stock some time. It appears that strontia and baryta water both allow the outgrowth of myelin forms with a freedom which is not allowed in lime water. Repetitions of this experiment with other solutions of baryta and lime have given results all pointing in the same direction, though most of the forms have been generally spherical and not twisting cylinders. The photographs in the right-hand column are set there for a comparison to be made later, when they will be explained. To test the possibility of small quantities of soda or potash present in the alkaline earths as impurities being responsible for the outgrowth in solutions of barium and strontium hydrate, a series of mixtures of lime water and soda (both N/100) in proportion varying from 1 to 9 down to 9 to 1, were prepared and compared with both the soda and the lime water alone. These showed that it was not a case of the presence of small quantities of lime preventing the appearances characteristic for soda, but rather of the presence of soda preventing those characteristic for lime water. The formation of buds, and a mass of spheroidal forms was conspicuous when there was more lime water than soda, even with four times as much, while with equal quantities of the two the appearances shown in Fig. 14 were obtained after 24 hours. Relatively small amounts of soda, possibly the amounts that may be extracted from ordinary glass vessels, may cause myelin forms to appear in lime water or baryta, and possibly strictly pure baryta would not give them. But however that may prove on further investigation, there is no such "precipitation" of lecithine by lime or baryta as to prevent the myelin forms appearing, and a Ringer's solution with calcium gives appearances essentially the same as those given by Ringer's solution prepared without calcium.

The film from which Fig. 10 was prepared shows that the strong solution of calcium chloride obtained from a bottle of pure crystals which had partly deliquesced gives a result similar to that with lime water in appearance. A similar solution of magnesium chloride gives a similar result. But both these solutions diluted to 1/100 of this strength allow a very free outgrowth of myelin forms, mostly but not entirely spherical.

The effect of different reactions on either side of the neutral point was also tested, using ten phosphate mixtures of pH ranging from 6·3 to 7·7. All showed myelin forms freely growing at first and finally a remarkable reticulation of the central parts of the mass. Fig. 17 is a reproduction of a photograph taken after five days where the reaction was that of the blood pH 7·3. Very similar appearances are seen in Fig. 18, another of the same series at pH 7·5, and in others not here reproduced.

(2) The *effect of high osmotic pressure* in the aqueous phase shown in Figs. 8 and 9 was discussed in connexion with them. And this is illustrated, too, by the action of strong solutions of the chlorides of magnesium and calcium just referred to.

(3) The *effect of adsorbed substances*, illustrated by Figs. 11 and 12, is further illustrated by the appearance of lecithine exposed for 24 hours to dilute gelatin solution (Fig. 19, No. 4) where the growth of myelin forms, which had at first been free, was after a short time almost completely arrested. By way of contrast with this, the coiled and twisted cylindrical protrusions formed under glucose solution (0·1 per cent.) in the same time (Fig. 20) make this arrest of growth in gelatin more conspicuous. But in a drop of human blood serum (Fig. 19, No. 1) their formation is fairly free; and with a solution of hæmoglobin obtained by laking washed blood corpuscles surface growth is obtained as luxuriant as with any fluid tested (Fig. 19). So that proteins do not all act as egg-albumin; hæmoglobin, so far from repressing, actually appears to promote the development of myelin forms.

Influence of Cholesterol on Lecithine.

Lastly, with regard to the influence of cholesterol, in all the experiments, excepting those used for kinema films, on the same slide and under the same drop of fluid a streak of lecithine at one side of the cavity and at the other one of lecithine containing a quarter of its weight of cholesterol was set up, and in this way any differences resulting from the presence of the cholesterol could be observed. In Fig. 15 the edges of the two streaks, that on the right containing cholesterol, had approached so that both appeared in the same field; the fluid here was ammonia N/100. The two edges appear, also in the same relative positions to each other, under dilute hæmoglobin solution in the two lowest photographs of Fig. 19 which are from the same preparation, that on the left after 40, that on the right after 90 hours. In Fig. 16 each pair of photographs was taken from the same slide, the right-hand ones from the lecithine containing cholesterol, the left from that containing none. Similarly, Fig. 18 can be compared with Fig. 17. Figs. 21 and 22 are also from lecithine containing cholesterol. It is too early to attempt a definition of the effect of cholesterol. But it does not at any rate hinder either surface growth or swelling. In some cases, as in lime water, it promotes the appearance of myelin forms, and generally it increases the regularity of the shapes.

THE TECHNIQUE OF SUPRAPUBIC PROSTATECTOMY.

FROM THE CLINIC OF PROF. HUGH CABOT,
UNIVERSITY OF MICHIGAN, ANN ARBOR, U.S.A.

BY J. BASIL HUME, M.B. LOND., F.R.C.S. ENG.,
CHIEF ASSISTANT, ST. BARTHOLOMEW'S HOSPITAL;
LATE INSTRUCTOR IN SURGERY IN THE
UNIVERSITY OF MICHIGAN.

THE general management of cases of suprapubic prostatectomy has remained almost unchanged in England since the operation was first introduced by Freyer, with the single exception of the modification of the "open operation" described by Sir John Thomson-Walker, and by Judd, of the Mayo Clinic. While the technique devised by Prof. Cabot may not differ greatly from that practised by individual surgeons in England, yet the whole procedure stands as an example of successful scientific surgery, based on sound experimental and pathological work, and establishes the importance of pre-operative drainage of the bladder. It was my good fortune to work for a year with him, and this article describing and explaining his methods may be taken as a token of my very sincere gratitude.

Pre-operative Drainage.

On admission to hospital bladder drainage is instituted in all cases as a routine measure. This is done either by the indwelling catheter or by suprapubic cystotomy, and is irrespective of there being urinary infection or marked residual urine for the following reasons. Any degree of prostatic enlargement sufficient to produce symptoms, will ipso facto have produced hypertrophy of the bladder wall, and consequent on this some thickening and congestion of the mucosa. At this early stage the "back pressure" will not be enough to impair the kidney function. But the bladder mucosa will have lowered powers of resistance, and experimental work has shown that though infection cannot be produced in the normal bladder, yet when urinary obstruction or overdistension is present organisms introduced will always cause infection. Further, when the pressure is suddenly released the congestion of the mucosa is increased, and actual petechial hæmorrhages may occur. It is axiomatic that when prostatectomy is performed micro-organisms enter the bladder from the surface of the body, either at the time of operation or shortly afterwards. In a congested bladder we have the "prepared soil" for the production of inflammation. Drainage will relieve the pressure and the congestion, and may further act by producing some degree of active immunity.

When much residual non-infected urine is present the so-called "back pressure"' is transmitted to the renal pelvis, producing varying degrees of hydronephrosis. The papillary ducts are unable to empty readily into the renal pelvis, and the "back pressure" is transmitted to the whole of the glomerulo-tubular system. The kidney becomes congested and renal function is impaired. This becomes apparent, first, as a deficiency in the excretory function of the kidney, and later by an actual retention in the blood of urea and other nitrogen waste products.

It is this type of case, with from 6 to 10 oz. of uninfected urine, and clinically a good "operative risk," which is responsible for the high mortality amongst cases in which bladder drainage is not carried out. Some marked disturbance of renal function may result from the sudden lowering of pressure, and congested renal tissue is again a "prepared soil" for circulating organisms, or for those ascending by the lymphatics from the bladder infected at operation.

If the residual urine is infected, but the patient's general condition good and his renal function tests satisfactory, the case is usually a better operative risk than a patient in a similar condition but with uninfected urine, because in the former case he has acquired an active immunity to such organisms throughout his urinary tract. Some estimate of the patient's general powers of resistance may apparently be obtained by examination of the cholesterol content of the blood. This, with the blood-urea estimation and the phenolsulphonephthalein excretion may form the renal "tripod of tests"—the term suggested by Mackenzie Wallis for the pancreas.

Renal Function Tests.

In Prof. Cabot's clinic two tests of renal function are employed, the blood-urea and the phenolsulphonephthalein. These are considered in conjunction with the general physical condition, the blood pressure, and the volume of urine secreted in relation to the fluid intake in determining the patient's fitness for operation.

The *blood-urea examination* indicates the degree of retention of the nitrogen metabolites; 0·2 per cent. is taken as a normal value and 0·4 per cent. as a high normal.

The *phenolsulphonephthalein estimation* is a test of the efficiency of renal excretion, and was devised by Rowntree and Gerharty. It is based upon the specific selective power of the renal epithelium to excrete even small doses of the dye, and is capable of accurate quantitative estimation. That it has not come into more general use in this country may be due to a misconception of the technique. The test is performed as follows: The patient takes from 200 to 400 c.cm. of water half an hour before the test; 1 c.cm. of a solution of phenolsulphonephthalein, containing 6 mg. of the dye to the cubic centimetre, is injected intravenously and the time noted. (A catheter is first placed in the bladder if an indwelling catheter is not being employed.) The catheter is allowed to drip into a white kidney basin or a cup containing sodium hydroxide solution and the time of appearance of the dye noted. The urine is then collected in a clean bottle for one hour from the time of appearance (not the time of injection as is sometimes the case) and a further specimen collected for the second hour. Enough sodium hydroxide is added to each specimen to make it strongly pink without precipitating the phosphates. The amount of dye excreted is estimated by comparison with a known standard in a colorimeter. An appearance time of from three to six minutes is normal and a total function for the two hours of 80 per cent. or over. The total function should be at least 50 per cent. before prostatectomy is performed. The appearance time alone does not give any very reliable information. Sometimes a small quantity of dye comes through fairly early in a damaged kidney. When the appearance time is long, but the total function is good, it means that the catheter is not in the lowest point of the bladder, or that a large post-prostatic pouch is present.

An interesting piece of evidence of the effect of "back pressure" on the renal function is shown by this test. When performed at the time of the first catheterisation of a patient with much residual urine satisfactory figures may be obtained. If it is repeated in three or four days a very marked drop will be noticed, and this has been ascribed to the decompressing of the kidney following the release of back pressure. This allows a great increase in the blood within the organ, and swelling and congestion take place, with a consequent diminution of the renal function. After this initial drop the renal function gradually increases, and unless the kidney has been severely damaged a good percentage will be obtained after a period of drainage. It is common knowledge that prostatectomy performed at the same time as retention is relieved, or in a case with much residual urine, is a highly fatal procedure.

Drainage by the Catheter.

A soft, red rubber catheter is introduced and tied into the bladder, the eye being at the lowest point at which it will just run. It is then connected by fine tubing with a bottle attached to the side of the bed. A rubber catheter is tolerated better than a silk web or gum-elastic one, though a mild urethritis will be produced even by its presence. This may be expected and has no bearing on the course of the case. The catheter is left in until the patient is ready for operation. A few days after its introduction a transient rise of temperature, from 100° to 103°, will occur, and last one or two days. This reaction is an almost constant one, and is due to the production of a mild grade of cystitis. In cases that are drained it is found that the cystitis following prostatectomy is much less marked than in the undrained ones. When the renal function tests are satisfactory such a case is usually ready for operation about one week after the reaction has subsided. About 40 per cent. of patients do not tolerate the indwelling catheter well, the usual reason being that the tip of the catheter is touching and perhaps ulcerating a projecting median lobe. They complain of pain or irritation and the catheter has to be removed. A small number of patients bleed, and here again catheter drainage is unsuitable.

When it is difficult to introduce a rubber catheter, it may be passed threaded over and stretched on a metal stylette, bent to the appropriate curve. If this fails a coudé or bi-coudé catheter should be passed and left in position for 24 hours, when the passage of a soft rubber catheter will probably be easy. If for any reason the indwelling catheter has to be removed, or if the patient is a poor operative risk, either clinically or by renal function tests, and prolonged drainage is likely to be required, the surgeon should proceed at once to drain the bladder by suprapubic cystotomy.

Suprapubic Cystotomy.

This may be performed either for drainage, as the first stage of the two-stage operation, when it is usually done under local anæsthesia, or as the first part of the single-stage prostatectomy after catheter drainage. It requires no detailed description though a few special points will be noted.

The bladder is distended in the usual way, and a mid-line incision made commencing one finger-breadth above the upper border of the symphysis pubis. This lower limit should not be transgressed. When the extraperitoneal, or perivesical fat, has been reached, the surgeon when incising or tearing through it should avoid any downward extension, in order not to open the loose cellular tissue of the retro-pubic space of Retzius. The separation of the bladder from the posterior aspect of the symphysis which is sometimes done may lead to infection of this space, adhesion of the bladder to the symphysis, and even to osteomyelitis of the symphysis. If the space is accidentally opened up it should be drained.

At this stage of the operation the lower limit of the parietal peritoneum will be seen as a fold on the surface of the bladder. It should be pushed upwards and gently stripped from the bladder with the finger. The bladder is next secured with tenaculum forceps or retaining sutures and incised in a vertical direction as high up as possible. A lower incision will tend to sink down behind the symphysis when the bladder contracts. The bladder is explored with the finger and the condition of the prostate investigated. Calculi, if present, are removed. A "de Pezzer" catheter is introduced, the mushroom end being just within the bladder, and the incision is sutured with catgut commencing below. The suture is at first through and through, but on reaching the catheter it is reversed and carried back to the lower end as an infolding suture through the muscle coat only. It is tied at the point of commencement. The abdominal wall is then closed in the usual way.

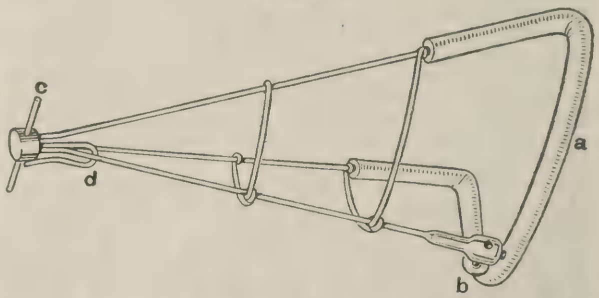
The patient having been returned to bed, the de Pezzer catheter is connected by tubing to a bottle at the side of the bed, and after the tubes have been filled with water, drainage is maintained by simple syphonage. If done for acute retention the bladder is, of course, not completely emptied, the catheter being clamped, and released at intervals for gradual evacuation. The bladder receives daily irrigation by alternate injection and aspiration of either boric lotion or 1 in 10,000 silver nitrate.

Prostatectomy.

It is, of course, unnecessary to state that the term prostatectomy is a misnomer. The hypertrophic nodules of gland tissue, whether they are believed to be derived from lobules of gland tissue or from embryonic rests, do not involve the whole gland, the remnants of which are compressed and form with the fibrous capsule the "surgical" or practical capsule from within which the adenomata are enucleated. (The enucleation of the adenomatous prostatic enlargement is essentially the same whether performed in one or in two stages.) The right forefinger is introduced through the internal sphincter to dilate it, and the mucosa of the prostatic urethra "cracked" immediately below. This is done along the line of least resistance, usually on the anterior or lateral wall, and the line of cleavage is found. The enucleation is then completed in the usual manner, assisted by a finger of the left hand in the rectum.

Great importance is to be attached to the proper control of hæmorrhage. Bleeding is usually very free from the prostatic cavity, and surgeons are so used to seeing this that some disregard what they would consider as very severe hæmorrhage in any other region. There can be no doubt that the amount of blood lost and the oozing of blood for several days afterwards lowers the patient's resistance greatly. Further, as the prostatic cavity becomes filled with clot, an excellent medium is provided for the growth of micro-organisms, and separation of these infected clots is liable to cause severe secondary hæmorrhage.

FIG. 1.

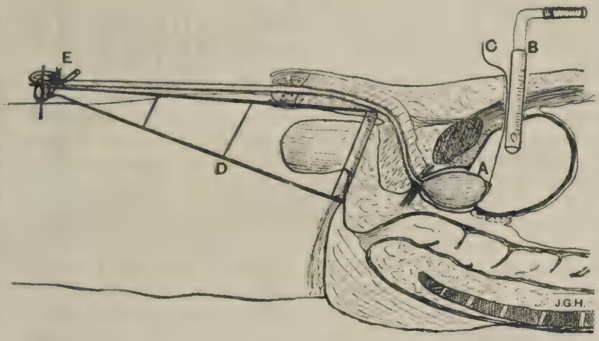


Cabot's Prostatectomy Splint. (*a*) Rubber-covered base. (*b*) Screw to allow of removal and replacement of rubber. (*c*) Cross-bar for attaching the tube. (*d*) Hook to attach loop of tape to anchor splint if necessary.

The method used for the control of hæmorrhage in the clinic was the hæmostatic bag of Hagner or Pilcher. As soon as all the adenomatous tissue has been enucleated a special sound (Hagner's) with an olive tip, or any well-curved sound, is introduced through the urethra and the tip made to appear in the incision. The tube connected with the bag is affixed to the olive tip, and the sound withdrawn carrying the bag with it, but leaving in the case of the Hagner bag a cord, and with the Pilcher bag the suprapubic tube, for the purpose of subsequent removal. Traction is made on the tube and the bag drawn down into the prostatic cavity carrying with it the mucosa and any lacerated tissue, thus preventing scar contracture at the internal sphincter and promoting the subsequent epithelialisation of the cavity. Air is then injected with a bladder syringe and the bag distended sufficiently to compress the cavity. The tube is then clamped and subsequently tied, the assistant maintaining steady traction on it throughout the operation. The bladder is inspected and all clot and debris removed. A large rubber drainage-tube is inserted and fixed in position with a stitch, the end being left long so that a tube can be connected for syphonage. This completes the two-stage operation, while the one-stage operation is completed in the way described under suprapubic cystotomy.

Dressings are applied and the end of the tube held by the assistant is attached to a cage, invented by Cabot, which maintains traction but still allows the patient to move. It consists of a tripod with a V-shaped rubber-covered base which is applied to the perineum. A large pad of cotton-wool is placed within the frame to support the scrotum. (Figs. 1 and 2.) Tension is released from the bag and the cage removed after 18 to 24 hours, though this may be done after 8 to 10 hours if much discomfort is caused. Should bleeding recur the cage can easily be replaced. About 24 hours after operation the air is released and the bag given an hour to collapse and then removed in the following manner: The drainage-tube is first withdrawn, and the portion of the urethral tube projecting beyond the meatus is cleaned with spirit lotion and then lubricated with K.Y. antiseptic jelly. Gentle traction on the suprapubic cord or tube will readily remove the bag. A de Pezzer catheter is introduced into the bladder, and any small clots removed by the injection and aspiration of boric lotion with a syringe. This also shows that the catheter is properly placed in the bladder for syphonage, which is then instituted, and should keep the patient quite dry. The scrotum is supported by a suitable suspensory bandage, as it appears that support tends to minimise the chances of epididymitis. This complication was rare in the clinic, and bilateral vasectomy was not considered necessary.

FIG. 2.



Median sagittal section through the pelvis, illustrating the application of Cabot's prostatectomy splint, or cage. A, Hagner bag in prostatic space. B, Drainage-tube with glass connexion and tube to collecting bottle. C, Cord to bag. D, Cabot's cage in position. E, End of tube doubled back and ligated, attached to cross-bar. The scrotum is supported on a large pad of cotton-wool.

The subsequent care of the patient is as follows: Daily injection and aspiration of the bladder with boric lotion, and the urethral injection of 15 c.cm. of a 1 per cent. solution of mercurochrome. This procedure aims at introducing an antiseptic into the prostatic space where infection is most likely to commence. All patients are put on extra fluids, and on 30 gr. of hexamethylene a day from the time of admission. The de Pezzer is replaced by a smaller catheter after four or five days, and at the end of eight to ten days a temporary clamp is applied to it for a short time and the patient instructed as the bladder fills to try to void per urethram. This is repeated twice and for longer periods on the next day and the patient usually succeeds in passing a small quantity of urine. The following day the catheter can be removed, and the patient instructed to void hourly, the suprapubic dressing being changed as required. In 24 to 48 hours the patient should be dry. If difficulty is experienced the probable cause is that the bladder has been markedly atonic and has not yet recovered its muscle tone. In this case a catheter (soft rubber) should be passed and tied in, and the wound will close rapidly.

The technique here described has been practised by Prof. Cabot for many years, and the clinic mortality is under 4 per cent., although the majority of the operating is done by his assistants. It is the principle underlying the procedure, rather than any special detail, that it is my hope this paper may elucidate.

THE PROBLEM OF THE
PHLYCTENULAR CHILD.

BY L. H. SAVIN, M.R.C.S. ENG.,
FORMERLY HOUSE SURGEON, ROYAL EYE HOSPITAL, S.E.;

AND

T. W. PRESTON, M.R.C.S. ENG.,
RESIDENT MEDICAL OFFICER, CITY OF LONDON HOSPITAL FOR DISEASES OF THE HEART AND LUNGS, VICTORIA PARK.

THERE is a great body of opinion that phlyctenules are due to tubercle. Prof. C. Pirquet, of Vienna, for instance, says in a private communication:—

> "In phlyctenular conjunctivitis we found regularly a positive tuberculin test; therefore, already in the last 15 years we considered it a tuberculous manifestation."

Fuchs states:—

> "In a great number of patients . . . . there are changes which are certainly tuberculous, most frequently appearing under the form of scrofulous lesions of the glands and bones and not infrequently also of pulmonary tuberculosis. But even in those patients who otherwise show no clinically demonstrable evidence of scrofula or tuberculosis, the examination with tuberculin (by subcutaneous injection or cutaneous inoculation) proves with rare exceptions the presence of latent tuberculosis. . . ."

An eminent ophthalmologist notifies every phlyctenular child as a case of tubercle to the authorities. Under the circumstances we thought our phlyctenular cases would offer a rich field for the study of tubercle. We have been disappointed. We examined very carefully a series of 50 consecutive, unselected cases, all with phlyctenules, though not all in the same stages of the disease. Twenty-two cases were in the very earliest stage with slight pyrexia, photophobia, excessive lacrymation, and with noses running, probably from the increased flow of tears down the nasal duct. We find that the temperature, at first 99·5°–100° F., falls to normal in a few days.

Case Records.

Out of a series of 50 consecutive phlyctenular cases 20 were males and 30 females; the average age was 10·43 years; 22 were febrile and 22 afebrile; the Pirquet reaction was positive in 18 and negative in six; the chest was apparently normal in 44 cases (doubtful in six); bones were normal in all but one, who was the subject of tuberculous disease; the glands in 28 instances appeared normal and were enlarged in 21 (five of these being tuberculous); the appetite was good in 39, poor in eight, and fair in three cases; the bowels were regular in 40, loose in three, and constipated in three cases. There was a history of previous measles in 31 cases, of whooping-cough in 19, of German measles in three, of scarlet fever in five, of diphtheria in two, of chicken-pox in 12, of pneumonia in three, of fits in four, and of rickets in four. Information was obtained regarding 383 living and 129 dead relatives of our 50 children. Out of the 50 families 24 members had died of tuberculosis and nine were suffering from it. The average number living in each home was 5·8, and the average number of rooms in each was 3·6. Twelve of the cases were verminous, seven had otitis, 22 enlarged tonsils, 24 coryza. In nine instances other members of the family had phlyctenules.

The following cases seem of sufficient interest to be reported more fully:—

CASE 2.—A boy aged 15. Phlyctenular since the age of 10. Had spent various periods away in the country. He had a high-domed palate, huge tonsils, and pus in the right antrum. The tonsils and adenoids being removed and the antrum drained, the phlyctenules disappeared.

CASE 6.—A woman aged 25. Pregnant. Phlyctenules for the first time in her life. Seen on 21/8/24. Fine baby delivered on 22/8/24. When doctor called next day the phlyctenules had disappeared.

CASE 22.—A girl aged 12. Had a bad family history of tubercle. She had signs suggestive of early hilum tuberculosis and was admitted to Victoria Park Hospital for further investigation. Signs were very indefinite, but X ray showed increase of the right hilum shadow spreading into the middle lobe. She had no sputum but fæces were negative for T.B. Pirquet reaction positive. Wassermann reaction negative.

CASE 24.—A girl, aged 10, also had suspicious chest signs, and gave a positive Pirquet reaction. On being admitted to hospital for further investigation, however, no definite signs were found and X ray showed a normal chest. Fæces were negative for T.B. A sister also had phlyctenules.

CASE 25.—A boy, aged 6½, had a tuberculous hip, with abscess in thigh.

CASE 35.—A girl of 7, with right convergent concomitant strabismus and phlyctenules since 1922. A dirty, verminous child with impetigo, one of a family of seven living in two rooms. Big tonsils and enlarged glands in neck. At the base of the left lung the percussion note was impaired and there were coarse râles. Pirquet reaction negative. We suggest fibrosis with bronchiolectasis following whooping-cough.

CASE 39.—An ill-nourished boy, aged 10½, formerly had iritis. Pirquet reaction negative to two repeated tests.

CASE 40.—A girl aged 10. At a first examination a few suspicious chest signs were found, but careful investigations in hospital over a period of a fortnight, including an X ray of the chest and examination of fæces, were negative. Pirquet reaction positive.

CASE 45.—A girl aged 17. The phlyctenules always appeared three days before the menstrual periods.

CASE 50.—Had a rickety chest and enlarged septic tonsils. She had a family history of tuberculosis and a positive Pirquet reaction. She had signs in her chest suggestive of enlarged mediastinal glands and fibrosis, but there was no definite evidence of tuberculosis. Wassermann reaction was negative.

We are indebted to Dr. Scott Pinchin and Dr. F. G. Chandler for permission to publish those cases admitted to Victoria Park Chest Hospital.

Discussion of Results.

We will now proceed to a discussion of our results. We started our investigations under the impression that phlyctenules were a manifestation of tuberculosis, which would probably be fairly easy to demonstrate in our cases. Yet we find that in many phlyctenular children there is no evidence to be found of tubercle, either clinically or in the laboratory. Six children gave with the Pirquet tuberculin skin test a negative result. There was no doubt of the activity of our tuberculin, as in each case other children tested at the same time with the same sample gave positive results. Prof. Pirquet himself, in an examination of 193 apparently normal children between 10 and 14 years of age, found his test showed 81 per cent. were tuberculous. The average age of our own children was 10·43 years, and 18 gave a positive, six a negative, result. Other observers in the past have also obtained negatives with the Pirquet cutaneous tuberculin test.

Table Showing Number of Negative Cases.

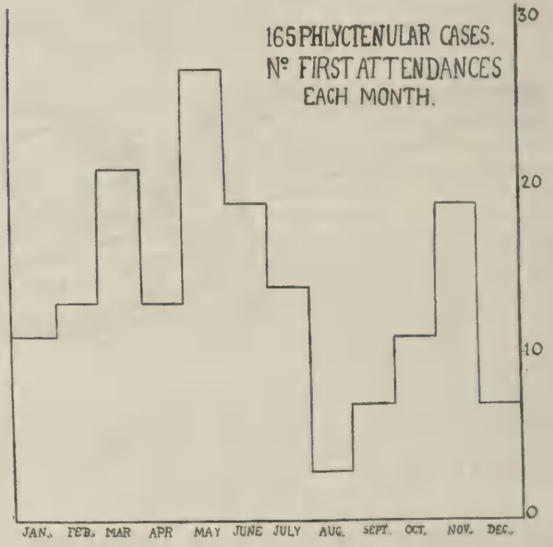
Observer.	Date.	Neg. cases.	Observer.	Date.	Neg. cases.
Ayrenx	1910	15	Derby	1908	5
Belensky Raskin	1911	8	Pyfer	—	8
Bruns	1912	40	Rosenbauch	1910	2
Davis and Vaughan	1912	12	Turien	—	4
			Weekers ..	1909	30
			Total		124

Bruns tried Calmette's ophthalmic tuberculin reaction on those 40 cases negative to Pirquet. He had 37 negative results. The tuberculin tests would therefore seem to show that tuberculosis is absent in many cases of phlyctenular conjunctivitis.

Incidence.

Tuberculosis is a disease without any very marked seasonal incidence. By the courtesy of Mr. W. J. Lindsay we are able to publish a graph showing the months of the year in which 165 cases of phlyctenular conjunctivitis first attended at the Royal Eye Hospital (Fig. 1).

FIG. 1.—*Seasonal Incidence Graph.*



We do not wish to lay very great stress on the marked seasonal variations, shown in Fig. 1, as we think they may be due partly to extraneous causes such as the hop-picking season, school holidays, &c. It would, however, be very interesting to compare a number of graphs of the same sort from different hospitals. We should be very grateful if any such were forthcoming.

In regard to age-incidence we found that the oldest patient in our series was 25, and the average age worked out at 10·43 years. This is consistent with the findings of other observers and cases of phlyctenular conjunctivitis in people over 30 are almost unknown. Tuberculosis occurs at all ages, and although certain organs are more liable to be attacked at different times of life, yet no type of tuberculosis is so limited to a particular period of life as would seem to be the case in phlyctenular conjunctivitis.

Tuberculosis in Relation to Phlyctenules.

Out of 512 relatives of our 50 cases a definite history of tubercle was obtained in 33 instances. An exhaustive inquiry into the family history of 50 normal control children gave 23 tuberculous out of 448 relatives. A strong family history of tubercle need not involve phlyctenules. We were privileged to examine the family histories and medical history sheets of the last 37 admissions into the West-square Orphans' Home. Of these 37 children, 20 had lost one or both parents from consumption. Yet since 1921 they have only had one phlyctenular case. This was a child admitted in May, 1924, from very bad surroundings. She came with phlyctenules already; but they cleared up shortly after admission to the institution. Miss Sharman, an alert old lady of 92, who founded the orphanage nearly 60 years ago and still manages it, states she has seen in all her experience very little eye trouble. In institutions where actually tuberculous children are treated, phlyctenules are not very common. At Victoria

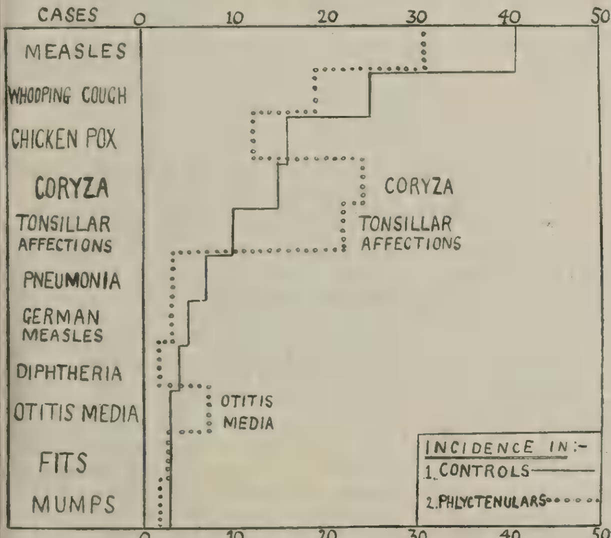
Park Hospital, for instance, among the notes of 240 tuberculous children, in 89 of whom tubercle bacilli were found in the sputum, we find no record of any phlyctenular case.

Phlyctenular conjunctivitis is a disease of the hospital class. Our honorary surgeons at the Royal Eye Hospital do not meet the condition in their private practices. Yet tubercle is no respecter of classes. Surreptitious inspection of a number of medical students showed several with marks of operations for glands in the neck. Phthisis is found in people of every social status. It seems probable, therefore, that while tubercle may be present in many phlyctenular cases, it is not an essential factor in the causation of the disease. It is not disputed that tubercle may be a predisposing cause; but there is little to prove that it is anything more.

Review of Series of 50 Cases.

We proceeded to a review of our series of 50 cases. In each of these we had exhaustive notes of previous illnesses, possible sources of sepsis, &c. But in considering these histories it was important to have a standard of comparison with the normal. We examined, therefore, 50 refraction children in a similar way as controls. The average age of our 50 controls worked out at 9·46 years, while our phlyctenular average was 10·43 years. In doing this we found certain common children's diseases were quite ruled out as possible causes of phlyctenules (see Fig. 2).

FIG. 2.



Comparison between previous illnesses of a group of 50 phlyctenular children and 50 control normal refraction children.

It will be seen that in the cases of measles, whooping-cough, chicken-pox, pneumonia, German measles, fits, and mumps, our control series of children had been quite as much affected as the phlyctenular. More phlyctenular children had suffered from running noses and ears, and many more suffered from, or had had removed, large tonsils and adenoids. At first we thought these increased proportions might be fortuitous, a misleading result due to the examination of insufficient controls. We examined, therefore, 50 more refraction controls for these special points, but were only confirmed in our findings that children with enlarged tonsils and adenoids and those susceptible to coryza were more predisposed than the normal to phlyctenules. We did not think that our cases were sufficient to enable us to decide whether otitis media was really a predisposing cause. In 21 cases in our series enlarged glands were palpated. Only in five cases did we decide these glands were definitely tuberculous. Our method was to palpate enlarged glands on several occasions running. The result was to prove that most of these enlargements were due to transitory causes such as tonsils, pediculi, and impetigo.

In nine of our cases there were other children with phlyctenules in the same family. Special attention was paid to these cases, as conditions were here presumably favourable to the disease. We found that these children were living in conditions of gross overcrowding. The average of these nine cases was 2·04 people to every room in their homes. We did not confine ourselves to taking particulars of bedrooms available, but counted indiscriminately for our average all rooms, sculleries, kitchens, &c., included. The inhabitants of the Waterloo neighbourhood are all rather overcrowded, so we decided to take control statistics. In the families of 50 healthy refraction children there worked out to be 1·446 people per room available. In our series of 50 phlyctenular children there were 1·56 people per room. Where more than one case per family was found the average was 2·04 people for each room available. It seems, then, that the more children are overcrowded the more predisposed they are to phlyctenules. We have already pointed out that phlyctenular kerato-conjunctivitis is seldom seen in Harley-street. Our cases were very largely drawn from squalid surroundings. This is shown by the large number of children who were verminous—12 out of 50. Squalid surroundings were found in one or two cases where we made domiciliary visits, which were rather distasteful and consequently soon given up.

Dental sepsis and intestinal toxæmia did not play an important part in our series. Only six had any irregularities of the bowels, and only eight loss of appetite. Malnutrition, we think, acts as a predisposing cause. It is a little difficult to summarise the diet of a large series of children, but in all there would appear to be too great an excess of carbohydrates. The following would be quite typical:—Breakfast: two slices of bread and margarine, some weak tea; dinner: potatoes and gravy (child will not take meat); tea: two slices of bread and margarine with more weak tea. This was the actual diet of a child 4½ years old. Rather an interesting sidelight upon diet was the statement of Case 39, when asked what he would have if he was going to order a luxurious feast. The child was no ascetic and he eagerly replied, "A lot of bread with some real butter, and a very large piece of cheese." Rather more ambitious was a girl of 8 who declared for a steak-and-kidney pudding and a pint of stout.

One child had nystagmus and spasmus nutans; no other children showed abnormalities on a neurological examination and all urines tested were normal.

Our investigations tended to discredit the theory that phlyctenular conjunctivitis is always an outward manifestation of "tuberculi-toxæmia." We now consider that the true ætiology of the disease is unknown. Many investigators have endeavoured to cultivate organisms from excised phlyctenules. Although some of the earlier workers claimed to find staphylococci or Koch-Weeks bacilli, the modern opinion seems to be that this was accidental contamination and that an early phlyctenule, before becoming secondarily infected, is sterile. Similarly, animal inoculation has been performed by many, but never with striking results. Our own inoculation experiments on rather a small scale were completely negative.

We are thrown back, then, on the theory that phlyctenular conjunctivitis is probably a manifestation of endogenous toxæmia, not necessarily tubercle. Further research is badly needed.

Treatment.

All our cases admitted to hospital cleared up very rapidly. We think surroundings have a great influence. Case 12, aged 11½ years, had suffered from phlyctenules eight years on and off. Away at Swanley Convalescent

Home, May, 1921–August, 1924, the eyes were quite well. Four days after returning home to the New Kent-road the phlyctenules returned. We do not consider tuberculin should be used unless the child gives a positive Pirquet skin reaction. Even then, if three injections of Tuberculin R (Rückstand) bring no improvement, we do not think it is worth continuing. Some cases certainly improve in a striking fashion after tuberculin injections. We are trying the effects of the injection of other protein solutions, but have not got sufficient results yet for publication. Prof. Pirquet, it is interesting to note, says: "As to the tuberculin treatment, we did a lot of it in past years (injections of small doses of old tuberculin), but in the last years we abandoned this treatment nearly entirely, being satisfied with the open air and nutrition treatment." He also points out that in his skin test other proteins often give reactions in tuberculous children, but not so regularly as tuberculin. Locally we are usually satisfied with frequent bathings and the application of 2 per cent. yellow oxide of mercury ointment. In cases of keratitis atropine is often necessary.

Conclusions.

Phlyctenular conjunctivitis is a disease of unknown ætiology but predisposed to by tuberculous infection (not always present), enlarged tonsils and adenoids, frequent colds, overcrowding, dirt, and malnutrition. There seems to be reasonable ground for attributing the cause to endogenous toxæmia (see Cases 2, 6, 45).

THE ALLEVIATION OF CHRONIC PROGRESSIVE DEAFNESS.

A RECORD OF ONE HUNDRED CASES TREATED BY THE ZÜND-BURGUET ELECTROPHONOIDE METHOD.

BY GEORGE C. CATHCART, M.A., M.D. EDIN.,
CONSULTING SURGEON TO THE THROAT HOSPITAL, GOLDEN-SQUARE, W.; LATE MEMBER OF THE SPECIAL AURAL BOARD, MINISTRY OF PENSIONS.

IN spite of the advance that aural surgery, in common with other branches of surgery, has made in recent years, otologists have to admit with regret that deafness, when it has become chronic, remains incurable.

Towards the middle of last century Sir William Wilde, the Dublin aurist, now chiefly remembered as the inventor of "Wilde's incision," summed up deafness and its treatment in an aphorism: "There are two kinds of deafness: one is due to wax and is curable, the other is not due to wax and is not curable." This is largely true still, and the reason is not far to seek; it is because we know so little about the ear. In his presidential address to the Otological Section of the Royal Society of Medicine in 1920, Sir Charles Ballance,[1] although he has written the completest work on the surgery of the temporal bone, was constrained to admit: "We are merely on the threshold of our knowledge of the ear"; and Dr. J. Kerr Love,[2] the leading authority on deaf-mutism, in his presidential address in 1924 said: "Outside of surgical treatment there has not been great advance in otology. We can hardly do more than we could do 50 years ago in the cure of deafness."

Chronic progressive deafness is of two kinds: first, that caused by a lesion in the sound-perceiving apparatus, called nerve deafness; and secondly, that caused by a lesion in the sound-conducting apparatus which may be either chronic otitis media or otosclerosis. For nerve deafness hitherto there has been no treatment. The late Mr. Hunter Tod, whose position as head of the largest ear clinic in the United Kingdom gave him a unique experience, said: "In a simple progressive nerve deafness nothing very much can be done."[3] Nor is the prospect more pleasing if we turn to the treatment of chronic otitis media. Sir William Milligan, than whom there is no greater authority, in a paper read before the Section of Otology in 1920,[4] asks: "What is the clinical course of chronic adhesive otitis media in so many of our patients?" and answers his own question by stating: "Slow but progressive deafness—perhaps some intermittent improvement—followed by a gradual loss of hearing, until finally a resort has to be made to some form of artificial aid or to lip-reading. I have painted a dismal picture, for in my opinion there has been no substantial progress in the treatment of adhesive catarrh during the past twenty years."

It may be urged that these writers take a gloomy view because they live in a dull, damp, dismal, and depressing climate and their patients, besides, live in gloomy cities where man does his best to prevent the sun shining by deliberately spreading a pall of smoke over the city. This not only lowers the vitality of the nervous system, which is bad for nerve deafness, but also engenders catarrh, which is bad for catarrhal deafness. Let us therefore cross the Atlantic and see what views are held in a sunnier climate concerning the second subdivision, otosclerosis, and also concerning tinnitus, which often causes more distress to the patient than the deafness. In a paper read before the California State Medical Society,[5] Dr. M. W. Frederick said: "I once asked an aural colleague what he did for people who applied to him for relief from noises in the head, and he told me he sent them to his enemies. This crystallises our attitude towards the otosclerotics. . . . There are some amongst us who can boast of hundreds of successful mastoid operations and count the number of favourably treated sinus thrombosis by the score, but not one of us has ever cured, or even relieved, a single case of otosclerosis."

The Zünd-Burguet Electrophonoide Method.

For many years I held the same opinion as these writers and had got tired of having to tell patients, after the classical remedies had failed, that nothing more could be done for them, when, a few years ago, an old patient, who had tried every kind of treatment for his deafness and tinnitus, told me that he had just heard of a new treatment which was being carried out by Dr. Helsmoortel, of Antwerp. On making further inquiries he found that the treatment had originated with a M. Zünd-Burguet, in Paris, and accordingly he went to see him. My patient, who was aged 43, had had otosclerosis for many years; a radical mastoid operation had been performed on the right side some ten years before, and he could only hear with a speaking-tube on each side. What troubled him most, however, was continuous tinnitus. The result of the treatment was at once unsuccessful and successful. The deafness was relieved but slightly and he still had to use his speaking tube, but the noises were so much decreased that life once more became endurable.

So impressed was I by this result and also by those recorded by Dr. Helsmoortel,[6] that I obtained an electrophonoide from M. Zünd-Burguet. This instrument reproduces the sound vibrations of the whole gamut of the human voice and thus gives a physiological stimulus to the ear. It contains three mechanical larynxes in which the vocal chords are replaced by vibrating platinum lamellæ; these are capable of producing in their desired intensity sounds resembling those of the human voice extending over five octaves and passing not merely through tones and semi-tones, but through all the vibrations between 80 and 3500. This is done by sliding platinum contacts along the vibrating lamellæ, the action resembling the movements of the fingers over the strings of a violin. It should be emphasised that the sounds produced are of varying quality and are variable at will. They are transmitted to the ear by modified telephonic receivers. A secondary current can be superimposed on the primary one which makes the sounds, and a vibratory massage of the whole auditory tract is produced. The complex vibrations produced by the electrophonoide act first as sonorous phenomena and secondly as dynamic phenomena, and it is to this double action that we must attribute the results obtained.

This instrument is a delicate physiological instrument, but, as all experimenters in physiology know, the personality of the experimenter bulks largely in the result of the experiment. Anyone who thinks that the instrument is an automatic machine and all that is necessary to get the results is to turn certain handles, will only succeed in ruining the instrument without benefiting his patient. There is not space here to discuss the theory on which M. Zünd-Burguet founded his treatment of so-called re-education, but those who wish to understand it should read the two books which he has published on the subject.[7]

Results of Treatment in 100 Cases.

I have had an electrophonoide in use for several years, and I now wish to put on record the result of treating patients suffering from so-called incurable chronic progressive deafness, many of whom also suffered from tinnitus. In order to find out the value of this treatment and also to obviate the fallacy that might exist by using other methods of treatment at the same time, I have taken 100 patients and treated them by the Zünd-Burguet method only. I feel justified, therefore, in stating that any benefit that has accrued to them must be due to that method and to that method alone. Every one of these 100 patients before coming to me had consulted two or more otologists of recognised standing, and many had consulted four or five, not only in London but in the provinces and abroad; in every case the deafness had been pronounced to be impossible of alleviation.

The treatment labours under two disadvantages. First, that it is not possible to tell from any tests made beforehand whether it will be successful or not. *There is a factor in deafness as yet unrecognised, the presence of which—or it may be the absence of which—determines the result.* Secondly, that as the deafness is chronic and progressive, and the improvement obtained after a full course lasts only six to nine months, in order to keep up the improvement another course is required. Sometimes, however, I have known the improvement to continue for one or two years without further treatment. The usual course of treatment consists of 30 sittings, but on account of this unknown factor it is necessary to give a preliminary course of 12 treatments; if considerable improvement occur it is worth while giving a full course; if there be no improvement it is not. The improvement must be considered in relation to normal hearing and not merely in relation to the amount of hearing the patient had previously; for instance, if a patient hear the ordinary voice at 6 inches or 1 foot and that distance be increased to 1 foot or 2 feet, even though the improvement be 100 per cent. or more, it still leaves the patient, for all useful purposes, as deaf as before; the improvement is in reality negligible, and it is useless to go on.

The tuning-fork tests afford no clue beforehand as to the possibility of alleviation. The watch and acoumeter I consider useless tests for any practical purpose in these cases and never employ them. The only useful tests are the tests made by the voice, as that is what these deaf people want to be able to hear. It is necessary, therefore, to compare the tests made by voice and whisper before and after the 12 treatments. We shall discuss the whisper first as the less important; indeed, I have been struck by the want of correlation between the improvement in the ability to hear the voice and the improvement in the ability to hear a whisper. The whisper used is one of constant strength; this is attained by taking a breath and forcing it out again, using only the residual air for the whisper. It may seem a work of supererogation to take a breath each time before forcing it out, but it is only by so doing that the whisper can be kept of constant strength, as otherwise one may begin to whisper sometimes with the lungs full, sometimes with them half full, and at other times with them empty, which would give a different result each time. I may mention an anecdote apropos of this. A deaf physician, a friend of mine, went with a deaf patient who was about to try a new treatment. The patient was tested by the otologist with a whisper so low that my friend could not hear it. After undergoing the treatment the patient was tested with a whisper so very much louder that my friend felt constrained to say: "It is indeed a wonderful treatment, Sir, because not only has it made my patient hear better, but it has made *me* hear better."

There remains, then, the voice, the only test that is of importance for these deaf people, as the whole aim and object of the treatment is to enable them to hear the voice when used in ordinary conversation. Some of my colleagues, albeit in quite a friendly way, have hinted that my results are too good to be true, and that, as in the story told above, I have used a louder voice when testing after the treatment than before. I shall therefore, at the risk of obtruding some personal details, say something on this point.

I have been compelled to study the subject of voice production more than most people, because until the age of 25 I had both a lisp and a stammer, and was besides unable to pronounce the letters "l" and "r," substituting "n" for both of them. I studied voice production and "visible speech" with a Mr. Jones, who was sent from America by Alexander Melville Bell and his son Graham Bell to start the first school of "visible speech" in Scotland. Further, I studied voice production and singing at Naples under the late Signor Scafati, the last of the old Italian *bel canto* school. I mention these facts to show that I have studied the subject and have, I believe, sufficient command of my voice and a sufficiently good ear to be able to keep the ordinary or conversational tone for testing.[8] For purposes of comparison, I may say that my conversational voice is heard by a normal hearing person at 80 ft., and my whisper at 20 ft.

The distance at which the voice and the whisper are heard by each ear is recorded before and after treatment. The measurements are all made by tape-measure and not by guess-work. The 100 patients come under three headings—namely: (1) 34 suffering from nerve deafness, (2) 33 suffering from chronic otitis media, and (3) 33 suffering from otosclerosis. No patients suffering from active suppuration in the middle ear have been included, nor cases of mixed deafness, nor cases of deafness due to syphilis, war injuries, or war neuroses. It will be observed that in some cases the tinnitus has ceased completely after treatment, although the deafness may not have been greatly alleviated; in others the tinnitus has not ceased, although the deafness has been alleviated.

In the accompanying tables the record of the left ear is given on the left of the column and that of the right ear on the right. A record is given first of the distance at which the ordinary conversational voice and whisper (W.) are heard by the left and right ear before treatment (B.T.) and then after treatment (A.T.) The second course of treatment has always been given six months after the first course unless there be a note to the contrary. The result after the second course is marked "2nd" and after the third course "3rd." In order to keep the cases in extended tabular form, so that they can be compared before and after treatment, I have had to save space by omitting histories of the cases, the records of the tests carried out after the 12 preliminary treatments, and also the results of the tests before beginning the second course. In a few cases the improvement had continued in the interval between the courses, and the hearing was better before beginning the second course than at the end of the first course ; but, as a rule, the hearing was not so good by a foot or so before beginning the second course.

Nerve Deafness.

Of the 34 patients comprised in this group 28 improved, including 15 males, whose ages ranged from 15 to 65, and 13 females, whose ages ranged from 9 to 77 ; six patients, including four males, aged 51, 51, 52, and 60, and two females, aged 51 and 52, did not improve. No. 2 had been advised to go to a school for the deaf and dumb, but after treatment was able to go to an ordinary school. No. 9, between the first and second courses, had a severe attack of influenza and acute otitis media of the right ear, for which paracentesis had to be done, but in spite of that the hearing has improved. No. 20 was tested after an interval of 18 months and was found to have improved considerably, while the tinnitus had not returned.

Nos. 29 to 34 did not improve after the preliminary 12 treatments.

Chronic Otitis Media.

In this group of 33 patients, 22 improved, comprising 10 males, whose ages ranged from 7 to 63, and 12 females, whose ages ranged from 22 to 60 ; 11, consisting of 5 males of ages 29 to 58, and 6 females, aged from 25 to 60, did not improve. Case No. 38 had been advised to go to a school for the deaf and dumb, but after treatment he was able to go to an ordinary public school. Cases Nos. 39, 47, and 55 were sent to me by Sir Charles Ballance ; some years before he had performed a radical mastoid operation, with grafting, on the right ear in No. 39 and on the left ear in Nos. 47 and 55. It will be observed that Nos. 39 and 47 could hear better in the operated ear, after treatment, than in the other ear.

Nos. 57 to 67 did not improve after the preliminary treatment.

Otosclerosis.

Of the 33 patients in this group, 18 improved; they comprised 4 males, aged 20, 35, 40, and 55, and 14 females, whose ages ranged from 27 to 62. Fifteen did not improve; they comprised 7 males, aged from 25 to 55, and 8 females, aged from 22 to 57. Cases Nos. 69, 72, 76, 80, and 81 had become worse after child-birth and had been told that they would become worse still if they had any more children; but Nos. 69, 72, and 76 have each had a child after the first course, and have not become worse. No. 68, although told that she would become worse if she had a child, had one after the first course and has not become worse. The importance of this may be realised when we find that Sir William Milligan,[9] in discussing otosclerosis and pregnancy, has gone so far as to raise the following point: "If in a case of advanced deafness where previous pregnancies have invariably increased the existing deafness, and where the patient is again pregnant, whether it is advisable or justifiable to induce premature labour." No. 71, tested after eight months, during which time she has been ill and confined to bed for two months, had only lost 1 ft. of the hearing in the left ear for the voice and 1 ft. for the whisper in the right, but the tinnitus had not returned. No. 83 returned for a second course, not because of deafness, but because the tinnitus, which had been relieved for three years, was beginning to trouble him again.

Nos. 86 to 100 did not improve after the preliminary treatment.

Conclusion.

I submit that my results show that this method of treatment, when properly carried out, affords the most substantial advance in the treatment of chronic progressive deafness of recent years, and that it deserves more serious consideration from otologists than it has hitherto received. Of the total number of cases, 68 per cent. have definitely improved after treatment. These comprise 81 per cent. of the cases of nerve deafness, 67 per cent. of the cases of chronic otitis media, and 55 per cent. of the cases of otosclerosis. The improvement in so large a proportion of patients, every one of whom had already been treated by the ordinary methods and pronounced incapable of improvement, cannot be lightly dismissed as a mere manifestation of suggestion or auto-suggestion.

As regards tinnitus, the records above show that this treatment not only alleviates it but often causes it to disappear completely. It is not an exaggeration, therefore, to claim that the electrophonoide treatment, when properly carried out, can and often does cure tinnitus.

Clinical and Laboratory Notes.

SUCCESSFUL COLLAPSE OF LUNG BY ARTIFICIAL PNEUMOTHORAX IN ADVANCED FIBROID PHTHISIS.

BY C. H. C. DALTON, M.A. CAMB., M.R.C.S.,
LATE HOUSE PHYSICIAN, CITY OF LONDON HOSPITAL FOR DISEASES OF THE HEART AND LUNGS, VICTORIA PARK.

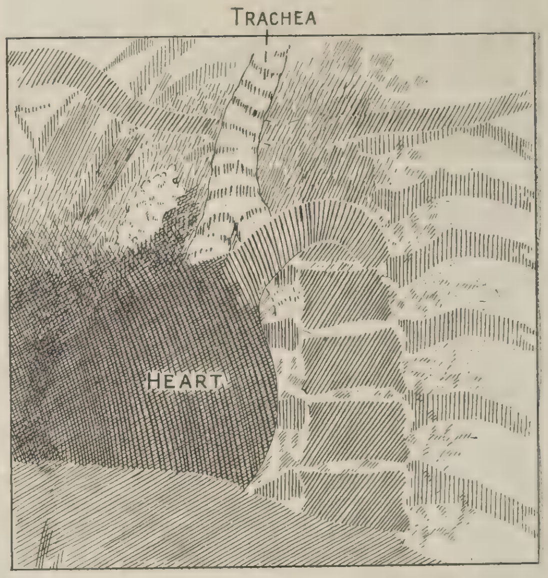
THE following case is of considerable interest, in that it shows that almost complete collapse of the affected lung was obtained in a very marked case of fibroid phthisis which, clinically, presented very little hope of this result being obtained.

The patient was a male, aged 22, and was admitted to this hospital on Nov. 7th, 1924, under the care of Dr. F. G. Chandler.

History.—Hæmoptysis in August, 1921; pleurisy and hæmoptysis in August, 1922. Treated at Brompton Hospital and at Godalming Sanatorium; in this hospital from July 18th to Sept. 8th, 1924; transferred to Whitwell Sanatorium, where he had repeated small hæmoptyses and lost weight

Condition on Admission.—Patient was well nourished; not anæmic. Signs of fibroid lung on right side, with large cavity in axilla; many fine superficial crepitations, especially at base; absent tidal movement; heart displaced very considerably to right. Left lung emphysematous; no signs of pulmonary tuberculosis. Tubercle bacilli were present in the sputum.

FIG. 1.



Tracing from skiagram, showing the condition before pneumothorax treatment was commenced. It shows the heart displaced completely into the right side of the thorax, along with marked displacement of the mediastinum.

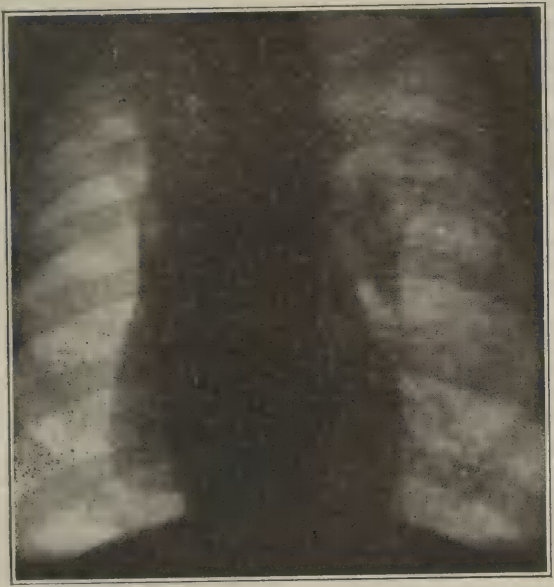
X Ray Examination.—Extensive fibrosis of the right lung; heart displaced completely into right side of chest (see Fig. 1); no signs of active disease in the left lung.

Operation.—I induced artificial pneumothorax on Nov. 14th, 1924, selecting a point situated 1 inch outside the nipple line in the second intercostal space for introducing the Riviere needle. Pleural fluctuations of − 6 + 2 cm. of water were obtained, and 400 c.cm. of air were introduced with a final reading of −2 +6 cm. of water. On the following day the initial fluctuations were − 2 +4 cm. water; 650 c.cm. of air were introduced and the final reading was −5 +1; it was probable that a considerable adhesion had been broken down during this refill. Collapse, as illustrated by Fig. 2, was obtained at subsequent refills, without difficulty.

It is observed that the heart and mediastinum, which were previously displaced to a considerable degree, have now been restored to their normal situation. Clinically, the patient is now making excellent progress.

In recommending the adoption of pneumothorax treatment in any individual case, Riviere[1] gives the following points as suggesting the possibility or likelihood of efficient collapse not being obtained owing to the presence of an adherent pleura or extensive adhesions: Long-standing widespread disease; extensive fibrosis with many fine superficial crackling râles; marked displacement of organs; absent tidal movement; a history of pleurisy.

FIG. 2.



Skiagram showing the right lung completely collapsed. It will be observed that the heart and mediastinum have been returned to their normal situation.

It is interesting to note that in this case all these points were present. I would observe further that the pleural space was found at the first attempt, and that at no time did the intrapleural pressure rise above −2 +6 cm. of water.

I am indebted to Dr. Chandler for his kind permission to publish this case.

SECONDARY SARCOMA OF THE PANCREAS CAUSING JAUNDICE IN A CHILD.

BY JAMES CROOKS, M.B., CH.B. EDIN.,
HOUSE PHYSICIAN, HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

THE interest of the following case lies in the clinical manifestations and in the unusual distribution of the metastatic growths.

On March 2nd, 1925, a girl, aged 10 years, was admitted to the Hospital for Sick Children, under the care of Dr. F. J. Poynton, to whom I am indebted for permission to publish this note.

History.—She had been ailing for two months, and had complained of headache. For a week before admission she had recurrent epigastric pain, and vomited twice.

Condition on Admission.—The patient was well developed and nourished, but was languid, pale, and puffy about the eyes. The abdomen was rather protuberant, but had no irregularity of contour; on palpation it was doughy, and the right subcostal region was full and resistant. The edge of the liver could be detected two fingers' breadth below the costal margin, and in the region of the gall-bladder an indefinite rounded mass could be felt. The spleen was not palpable. No evidence of disease of the heart or lungs was detected. Except for the absence of both knee-jerks, the central nervous system showed no abnormality.

While in hospital she continued to suffer from abdominal pains and headache. On the third day an icteric tinge appeared in the skin and conjunctivæ, and a small swelling suggesting bulging of the bone was noted over the lateral half of each supraorbital ridge. Next morning the girl passed an offensive clay-coloured stool, the fæces having been of a normal colour up to this time. Examination of the optic fundi showed swelling of the discs and striate hæmorrhages in the surrounding retinæ. The blood picture was unusual. Of 10,312 white cells 44 per cent. were polymorphs, 42 per cent. small lymphocytes, 8·5 per cent. large lymphocytes, 0·5 per cent. large mononuclears, 0·5 per cent. eosinophils, and 4·5 per cent. transitionals. A few myelocytes and normoblasts were seen. The red cells showed polychromatophilia and anisocytosis. The jaundice progressively deepened, and the stools remained clay-coloured. Attacks of epigastric pain increased in duration and severity, and the patient vomited after any food. The liver increased in size and the rounded swelling projecting below it was more readily felt. The bulgings over the eyes extended; that on the left, growing more rapidly, pushed the corresponding eye forward and downward, corneal ulceration resulting. Pressure over the shafts of the femora caused pain. The child died on March 25th, after three weeks in hospital.

Post-mortem Examination.—Both ovaries were found to be equally enlarged. They were 3 in. long by 2 in. broad, dark purple in colour, lobulated, and partly nodular and partly cystic. The pancreas was converted into a firm mass 6 in. long by 2 in. thick, which was attached by its right swollen extremity to the duodenum, where it surrounded the common bile-duct. On section it was white and cirrhotic in the centre, and hæmorrhagic at the periphery. The dark grey-green liver reached four fingers' breadth below the costal margin, and the gall-bladder was distended with dark viscid bile. Both the kidneys and adrenal glands appeared healthy. The thymus was large for the age of the child, hæmorrhagic purple in colour, and nodular. A lymph gland at the root of the right lung and another at the bifurcation of the trachea both showed metastatic enlargement. The left orbit was packed with tumour growth, which pushed forward the eye and spread to the frontal bone, causing the swelling over the supraorbital ridge. Tumour growth was present in the right orbit. There were deposits of new growth over the anterior surface of the fourth and fifth dorsal vertebræ, on the internal aspect of the left ramus of the pubis, and on the outer surface of the calvarium. There was a recent extensive subdural hæmorrhage over the vertex of the brain. Histologically very little gland tissue was found in the ovaries. It was replaced by sarcoma of the small round-cell type. The blood-vessels being ill-formed, there was much hæmorrhage. The pancreas was extensively invaded by sarcoma, small groups of acini being widely separated by masses of neoplasm. The thymus showed metastasis of the same type of growth, and the tissue of the lymph gland from the mediastinum was almost entirely replaced by it. Sections of the other tumour masses described also revealed small round-celled sarcoma, while those of the spleen, kidneys, adrenals, and mesenteric glands proved these organs to be healthy. An interesting point was that the liver showed definite early unilobular cirrhosis; the portal tracts were broadened, the small bile-ducts contained bile casts, and in the liver cells were granules of bile-pigment. There was no evidence of metastatic growth in the liver or lungs.

The conclusion was that sarcoma of the ovaries was the primary disease. Sarcoma of the ovary in girls is bilateral in about half the cases.[1] Obstructive jaundice, a rare condition in a child of this age, presenting as it did all the features of the same condition caused by carcinoma of the head of the pancreas in the adult, was due to secondary sarcoma in the pancreas.

Medical Societies.

ROYAL SOCIETY OF MEDICINE

SECTION OF MEDICINE.

A meeting of this Section took place on April 28th, Dr. Robert Hutchison, the President, being in the chair.

Metabolism and the Sympathetic System.

Prof. E. Leschke (Berlin University) read a paper on this subject, in which he discussed some of the problems connected with the regulation of metabolism by sympathetic centres in the diencephalon. Until quite recently, he said, the profession concentrated upon the influence of the endocrine glands as the causative agent in the production of these disturbances, and when he first put forward the view that such troubles as diabetes insipidus, dystrophia adiposogenitalis, and some forms of glycosuria had a nervous rather than a glandular origin, he was severely criticised. Research during the last few years, however, showed that there was justification for following the line of Claude Bernard, but in the inter-brain instead of the medulla. The diencephalon was, however, very inaccessible for investigation, and to reach it the same technique as for hypophysectomy had to be employed. The difficulty was increased by the close proximity of the pituitary body. Sometimes in diabetes, &c., the pituitary was very carefully examined, but the diencephalon was not regarded as sufficiently important to examine. Karplus and Kreidl, in 1909, obtained clear evidence of the presence of sympathetic centres in this region, and found that its irritation resulted in pupil dilatation and palpebral retraction, as well as vasomotor changes and sweating. Aschner, in 1912, after stimulation of the hypothalamic region, got glycosuria, polyuria, and contraction of uterus, rectum, and bladder. In the same year the author demonstrated the presence of temperature-regulating centres in the diencephalon—i.e., in the tuber cinereum. After irritation of the hypothalamic region there was found to be a diminution of protein metabolism.

Prof. Leschke abandoned the theory of pituitary causation of the conditions named because neither experimental hypophysectomy nor complete destruction or atrophy of the pituitary gland in the human caused polyuria. He had seen disappearance of diabetes insipidus after encephalitis, which was a cerebral, not a glandular disease. The frequent occurrence of diabetes insipidus after skull injuries was easily explicable, as the infundibular region, fixed to the sella turcica, was one of the most exposed parts of the brain to shock and counter-shock. The persistence throughout life of polyuria, in many cases with nervous troubles, and the absence of true pituitary symptoms favoured the theory which located the cause in the diencephalon. Moreover, in some cases even large doses of pituitrin failed to increase urine concentration. Diabetes insipidus seemed to him to be an interesting example of the autonomic nervous regulation of metabolism. Disturbance of this regulation led to polyuria.

With regard to dystrophia adiposo-genitalis, he did not think the posterior lobe of the hypophysis had much influence on either growth or metabolism; but destruction of the anterior lobe nearly always caused one of Fröhlich's symptoms—i.e., genital atrophy. But all the classical phenomena of Fröhlich's syndrome could be experimentally caused by a mere lesion of the diencephalon. He said he believed that the diencephalic centres always played the foremost part in dystrophia adiposo-genitalis, but admittedly the pituitary body exerted a great influence on the function of those centres. Cases of diencephalic origin seemed the most resistant to any form of therapy. The sympathetic centres regulating metabolism and sexual development were closely related but not identical.

In diencephalic obesity the cause was not a lowering of basal metabolism, and in these cases it was necessary to make a functional diagnosis of metabolism—i.e., at rest and after meals of different kinds. These obese cases showed a tendency to oxidise sugar insufficiently, and to change it at once into a fatty deposit, and the respiratory quotient was high. These patients showed a disturbance of the vegetative nervous balance, with more marked irritability of the para-sympathetic part. A variation of pleuriglandular insufficiency with troubles of sympathetic innervation showed a peculiar pigmentation of the skin, which he termed "dystrophia pigmentosa." It might seem wrong to associate the diencephalon with diabetes now that its pancreatic origin had been proved by the success of insulin therapy, but all glandular activity was under the regulating control of the sympathetic nervous system.

In conclusion, Prof. Leschke said there was a close relation between endocrine glandular activity and sympathetic nervous regulation, and he hoped that by continuing this combined method of research—experimental, clinical, and pathological—a better and more complete understanding of the physiology and pathology of the vegetative nervous system would be arrived at.

Discussion.

Dr. Parkes Weber said he had seen a man 40 years of age whose whole body was covered with small blackish pigment nævi and who had peculiar cushion-like soft parts at the ends of his fingers and toes and ulnar deviation of the fingers. But there was no typical dystrophia adiposo-genitalis. He regarded that case as allied to Recklinghausen's disease, and held that there was tuberose sclerosis of the brain, as for some time there had been a progressive hemiplegia of the right side of the body.

Dr. W. Langdon Brown said he was inclined to agree with Prof. Leschke's conception of the hypothalamus as the head ganglion of the sympathetic nervous system; but he suggested it was possible that the pituitary gland was a mechanism through which the hypothalamus acted—namely, through its posterior lobe. Pituitrin was a powerful antidiuretic which would hold up excessive output of urine for as long as 16 hours. He thought it unlikely that this glandular structure should be placed so close to the hypothalamus unless there were a functional relationship between the two. Pituitrin would even act on the denervated kidney, and he suggested it was put into action through the nervous system. One of the great difficulties in pituitary gland cases was the very partial grouping of the symptoms. Prof. Leschke's suggestion that many of the regulations of the output of water were regulations in the balance between the tissues and the blood was along the present trend of physiology. He had seen a patient for diabetes insipidus, and no evidence of pituitary lesion was found. Some months later she was sent because she had cerebral symptoms, and there were obvious signs of cerebral—probably pituitary—tumour. Yet there was only a slight tendency to polyuria. Ultimately she died, and there was found a tuberculoma of the pituitary body. The case showed that as the lesion advanced in the pituitary diabetes insipidus became a less marked feature. In diabetes too much had been made, he thought, of the pancreatic theory. Allen's work showed that if hyperglycæmia was persistent it would ultimately damage the cell-ions. He did not think all cases were pancreatic in origin, but if hyperglycæmia were allowed to persist they would become so. Diabetes should be regarded as a symptom-complex.

Hypoglycopyresis.

Dr. Otto Leyton read a paper bearing this title. It opened with an argument against the practices of naming diseases after men or according to the most prominent symptoms, the chief objection to the latter being that the most prominent symptom of a disease might be absent in a particular case. A nomenclature based on the morbid causal changes in the tissues was much to be preferred. In 1917 he pointed out that the introduction of small quantities of certain bacterial poisons depressed the carbohydrate metabolism profoundly. When the onset of diabetes mellitus was insidious, there occurred a stage when there was neither polyuria nor glycosuria, but only a slight diminution in the efficiency of carbohydrate metabolism, and this stage he called hypoglycopyresis. There was a close simile between this and hyperthyroidism, as in a mild case of the latter there might be no symptoms unless the patient had an emotional orgy, while in early hypoglycopyresis there was neither polyuria nor glycosuria unless the patient had a carbohydrate orgy. Concerning the question of how the condition could be recognised if there were neither polyuria nor glycosuria, the method he had adopted of recognising deficiency in the carbohydrate metabolism was based on the work of Woodyat and Sansum, who gave intravenous injections of glucose and determined the amount the normal person could receive without developing glycosuria. Dr. Leyton's only modification was that instead of depending on the glycosuria, since renal thresholds differed in various persons, he took samples of blood and assumed that if the sugar in it remained below 0·2 per cent. when the individual was receiving 0·8 g. of dextrose per kilo body-weight per hour for two hours, the carbohydrate metabolism of such person was normal. If he could not burn or store 0·7 g. per kilo body-weight per hour, the carbohydrate metabolism was depressed; but such a person would not be likely to suffer from glycosuria. Dextrose was injected intravenously because oral administration was fallacious. Only the purest dextrose in sealed tins should be used, and it should not have been kept exposed to the air; also distilled water which had been autoclaved directly after distillation should be employed.

Dr. Leyton related several instructive cases. The paper was not discussed.

SECTION OF OTOLOGY.

A MEETING of this Section was held on May 2nd, Dr. J. KERR LOVE, the President, being in the chair.

THE MASTOID EMISSARY VEIN.

Mr. ARTHUR CHEATLE submitted a contribution entitled the Mastoid Emissary Vein and its Surgical Importance. In illustration of his subject he showed a number of specimens and many photographic slides. He said this small vessel had received but little attention from English anatomists, and still less from aural surgeons in their published works, yet its clinical importance on occasion loomed large. In most of the 1500 skulls examined in this connexion the emissary vein was single and small, originating on the outer edge of the lateral sinus groove, just below the bend, and having a short course in the substance of the bone, in an upward and backward direction, and opening on the surface just behind the upper posterior edge of the base of the mastoid. A branch of the occipital artery passed through the same canal. It was not uncommon for this vein to be absent, nor for it to be unilateral. Its diameter might be that of a mere thread, that of a wax match, or it might be one-quarter, three-eighths, or half an inch. Where it was over one-eighth of an inch in diameter it must increase the size of the external jugular vein. The emissary vein might be single at its origin and double at its exit; or double at both origin and exit; or double at origin with three points of exit. The vein was always in the substance of the bone; the canal was never surrounded by cells nor running freely across them. The length of its course might be one-sixteenth to three-quarters of an inch, and its exit might be low down in the digastric fossa, or even entirely behind it. In the lower animals it was frequently associated with the petrosquamosal sinus, but only in the human when it was very large. In the large series of skulls examined there were two only in which the lateral sinus came to an abrupt end, emerging through an enormous mastoid foramen, with complete absence of the lower part of the lateral sinus.

Surgical Importance of the Vein.

There was a risk of opening this vein at its exit in making incisions, or in stripping up periosteum in various operative procedures; also in the treatment of lateral sinus thrombosis, or cerebellar abscess, and in doing decompression. Usually, bleeding from it was trivial, and could be easily controlled, but in cases where the vein was of large size wounding of it might be dangerous. In those instances he had suggested the use of a muscle plug. The vein might constitute a channel for the conveyance of septic thrombosis, and it might be infected from the lateral sinus, which was, indeed, inevitable when the vein was very large. Or this sinus might be secondarily infected after operation for mastoiditis. Sepsis could spread from this vein to the diploë, causing local inflammatory signs in unexpected parts of the skull. If the sepsis extended down the occipital and external jugular veins it would be necessary to ligature and excise the external jugular.

Discussion.

Dr. DAN MCKENZIE spoke highly of the industry displayed in this research, and pointed out the importance of actually cutting specimens, as contrasted with mere examination, in order to gain the needed familiarity. In an emergency, with no antiseptic wax to stop dangerous bleeding, he suggested the use of a plug of ordinary toilet soap, which he had found to be sterile.

Dr. LOGAN TURNER spoke of the great variation in structure encountered by the surgeon practising otology. In a report he had read of a case of fatal cavernous sinus thrombosis and meningitis, the process of infection was found post mortem to have extended from the occipital vein through the mastoid emissary vein, to the lateral sinus, and thence through the superior petrosal to the cavernous sinus.

EXHIBITION OF CASES.

Bilateral Mumps Deafness.

Mr. NICOL RANKIN reported the case of a girl, aged 10, who, three and a half months ago, had a pyrexial attack and some transient vertigo, followed by ringing and thumping in both ears. A fortnight later she suddenly became deaf on the left side, and next day on the right. At this time she was found to have mumps. Vestibular tests showed a normal ocular response, but no vertigo, though prolonged rotation caused vomiting.

Several members stated that they had found pilocarpine for this condition disappointing.—Sir WILLIAM MILLIGAN said that in some of the cases of the kind which he had seen he thought there was a localised basal meningitis.

Sudden Bilateral Nerve Deafness.

Dr. MCKENZIE showed a girl, 10 years of age, who woke up one morning two years ago with almost total deafness on both sides. There was no vertigo, nor any other apparent illness, and the ears had not discharged. Mumps occurred a year after the deafness commenced. The Wassermann test was negative.

The PRESIDENT thought the condition was probably a neuritis of the eighth nerve, though he did not know why it should affect the cochlear branches.—Mr. CHEATLE regarded the case as a functional one; probably the child had been in association with deaf people. He advocated putting the child into new surroundings and treating her with faradism.—Sir JAMES DUNDAS-GRANT agreed with Mr. Cheatle's view, but he did not doubt the deafness. The mother stated that the child had had a fall on the day preceding the onset of the deafness, striking the back of her head.—Sir **William Milligan** thought the suddenness of the onset in this case excluded the neuritis idea. His view was that the diagnosis rested between some vascular change and a hysterical condition. He suggested X ray examination, to search for bone damage as a result of the fall. Auto-suggestion might be a useful form of treatment.

Radical Mastoid Operation Performed by Nature.

Mr. **Archer Ryland** showed a woman, aged 38, who had suffered from chronic middle-ear suppuration, and had a cholesteatoma; the process had resulted in decay of bone and the complete performance of the radical mastoid operation without surgical interposition. When he saw the patient the whole cavity had been epithelialised.

Sir J. **Dundas-Grant** said the case enforced the view he had put forward that when the lining of a cholesteatomatous cavity was homogeneous, well attached, and shiny, it should be conserved, as it served the purpose of a skin-graft.

Corrigenda.—Dr. Langdon Brown writes: "I am sorry to observe several rather serious inaccuracies in your report of my opening remarks in the debate on Endocrine Therapy at the Royal Society of Medicine (The Lancet, April 4th, p. 739). The statement that 'The oral method was very uncertain except in a few cases of pituitary administration,' would exclude thyroid extract which I gave as the classical example of successful administration by the mouth. In the sentence 'Parathyroid had a great function as a katabolic agent; if its normal secretion were diminished there was an accumulation of waste tissue in the body,' *thyroid* should be read. The next sentence relates to parathyroid, though I did not claim it would probably produce a 'great' rise in the calcium content of the blood. Nor did I say that adrenalin was of value as a local anæsthetic, but that it was used for its local effect on blood-vessels, as in local anæsthesia, meaning that it prevented too wide diffusion of the local anæsthetic, in this way. In saying that pituitary extract is valuable in diabetes, unless the word 'insipidus' is added the reference might be to diabetes mellitus. I did not claim that 'many [diabetic patients] were able to return to normal life without the continuance of insulin.' I said they were keeping free from glycosuria with a normal blood-sugar; but they continued to diet, which is not returning to a normal life."

Dr. Harold J. Phillips informs us that in the report of the British Congress of Obstetrics and Gynæcology (The Lancet, May 2nd, p. 921) the remarks ascribed to Prof. M. H. Phillips were made by himself.

Reviews and Notices of Books.

FRACTURES AND DISLOCATIONS.

By **Philip D. Wilson**, A.B., M.D., F.A.C.S., Instructor in Orthopædic Surgery, Harvard Medical School; and **William A. Cochrane**, M.B., Ch.B., F.R.C.S. Edin., University Tutor in Clinical Surgery, University of Edinburgh. London: J. B. Lippincott Company. With 978 illustrations. Pp. 789+xv. 45*s.*

This is a work of international significance. The two names on the title-page assure it a respectful reception from the surgical public, but in America it represents more than individual opinions. We are told in the preface that the facts and views herein stated represent as faithfully as possible those of the staff of the Fracture Service of the Massachusetts General Hospital, Boston, Mass., and that this staff is composed of six surgeons, two from each of the two surgical services and two from the Orthopædic Service. The staff has arrived at practical unanimity on its special subject, and more than this, a conference of representative surgeons of wide experience from different sections of the United States and Canada, which met in Boston in 1922, accepted practically all the recommendations of the Boston Service and made additions to them which are here included.

In a foreword Dr. Daniel Jones, chief of staff of the Massachusetts General Hospital Fracture Service, records his approval on behalf of that staff of the views expressed in this book. As to the British side, it is stated that "in respect to treatment a substantial agreement exists in the two institutions on opposite sides of the Atlantic." This work therefore comes to us with weighty authority behind it, and thus stands in quite a different category from works on fractures which represent the experience and methods of one surgeon only. Throughout the book the functional value of results is insisted upon, and the lessons learnt during the war are applied in as far as they are suitable to the conditions of civilian life. The futility of methods of treatment which secured maybe a perfect anatomical result as regards the bone, but left the patient crippled by adhesions and atrophied muscles, is now apparent to all. The modern surgeon realises to-day that the condition of the soft parts needs almost as much thought and care as that of the bones. The authors have tried to keep in mind the needs of the general practitioner, and therefore have stressed non-operative methods of treatment. They have, we believe, succeeded in indicating lines of treatment which are not beyond the reach of well-equipped practitioners.

The first three chapters are taken up with general considerations and the declaration of principles. The value of early active movements and gentle massage is recognised and the importance of the innovations (often misunderstood) of Lucas-Championnière is emphasised. The authors are strong advocates of the use of plaster-of-Paris, but caution readers against its use in an encircling form. If so applied it should be divided at least on one line. Traction is recommended in nearly every case of fracture in the continuity of a limb and skeletal traction by means of one or other form of "ice-tongs" is advocated in many cases, chiefly because of the freedom which it allows for massage and passive and active movements of neighbouring joints. For compound fractures, débridement is recommended as even more useful in civil than in military surgery. Plating operations and bone suture are rarely to be resorted to. A useful table of the methods of fixation to be used in injuries of the various regions is appended to the third chapter. In this the Thomas splints occupy an important place, as was to be expected. There are 16 chapters on fractures and dislocations of the various regions of the body. Each chapter begins with a consideration of the normal anatomy of the part, illustrated by a plate or plates from standard works on anatomy, and followed by a discussion of the nature and mechanism of the injury and a statement of general principles as applicable to that particular region. The evidence of X ray plates is largely relied upon for diagnosis. The method of treatment which has been found most successful by the authors is then described. Few if any statistics of the relative frequency of different fractures and dislocations are included. The subject of dislocations is treated perhaps too briefly, little stress being laid on their anatomical varieties or on the various methods appropriate to their relief.

A severely practical tone is adopted throughout the book, which is copiously illustrated, largely by photographs and reproductions of X ray plates. The illustrations of cases undergoing treatment by traction, splinting, and other methods leave much to be desired, as is so often the case in books of this sort. It is no doubt desirable that the actual treatment used should be accurately represented, but the mass of irrelevant details which assert themselves in a photograph to the obscuration of more important matters, could well be spared. Diagrammatic drawings faithfully representing the essentials of the photographs would be more valuable as a means of instruction to the reader. We commend the suggestion to the authors for adoption in the second edition, which will no doubt soon be wanted, for the book should make a wide appeal.

Side-lights from the New Psychology.

By Evelyn Saywell, L.R.C.P., L.R.C.S. Edin. London: The Scientific Press, Ltd. 1924. Pp. 100. 3*s.* 6*d.*

This book, addressed to nurses, gives enough of the essentials of modern psychology to help in the understanding and handling of nervous patients and children. It follows to a great extent the teachings of Jung and suffers from that avoidance of difficulties which seems inevitable in books of this nature, though the author is perhaps right in thus making easy the path of the reader. Her separation of psycho-neuroses into central nervous system types and sympathetic nervous system types, however, would have been simpler and more in accord with clinical observations if she had applied it to symptoms and not to patients. There is little attempt at instruction in formal psychotherapy; in fact, Dr. Saywell leads up to the conclusion that the psychological aim of nurses and parents should be to look after their own ideas and adaptations before accepting the responsibility of guiding children. In the handling of a nervous child the treatment of the parent is often the first necessity, and for such an occasion there are some home truths on p. 73, beginning with a reference to "the deadly power possessed by the adult for hindering the development of children. . . ." It remains doubtful whether the method of self-analysis described on p. 94 can produce results. This is a useful little book; it is a pity that the title gives no indication of its nature and aims.

Instinct, Intelligence, and Character.

By Godfrey H. Thomson, Ph.D., D.Sc., Professor of Education and Head of the Teachers' Training Department, Armstrong College, Newcastle-on-Tyne. London: George Allen and Unwin. 1924. Pp. 281. 10*s.* 6*d.*

The lectures that make up this book were delivered by the author as Visiting Professor of Education at Columbia University, New York City, and they embody what is most useful in psychology as applied to education. Stimulating rather than dogmatic, the author nevertheless rarely leaves us in doubt about his own views, which are freely supported by experimental results, though full weight is given to those theories that are incapable of experimental proof. The reader will, apart from the technical aspect of the subject, obtain a sound idea of the progress that psychology has made from the purely intellectualist standpoint of Herbart to the study of sentiments and instincts from the psycho-analytical point of view. The subject is made interesting and intelligible to the general reader without any sacrifice of range or accuracy; success of that kind is rare in a book on psychology, and this work should find a circulation beyond those whose interests as educationists lead them to read it.

The Medical Annual, 1925.

A Year-Book of Treatment and Practitioners' Index. Bristol: John Wright and Sons, Ltd. 1925. Pp. 600. 20*s.*

This well-known annual, which now appears for the forty-third time, will be as welcome as ever. Almost every member of the medical profession should find it of use. To some it is the means of keeping them abreast of recent knowledge when time and leisure do not permit of more than a rapid glance at the medical weeklies, while to others it will be the reference book which enables them to turn up original papers on particular subjects, a sort of card index of the year's progress. As usual, the editors, Dr. Carey Coombs and Prof. Rendle Short, contribute an introduction in which they survey the tendencies of contemporary medicine. They refer to recent work on the injection of foreign protein for certain disturbances such as migraine, epilepsy, and asthma; to the administration of chlorides in tetany; to the surgical invasion of the field of cardiology with the operations for angina pectoris. At the same time they discuss the trend of opinion on subjects which have been described for the first time in previous editions. For example, they point out that massive doses in radiotherapy appear to be on the wane, that hilus shadows are beginning to be looked upon with suspicion, and that thoracic surgery continues to develop. As usual, this volume contains many excellent plates, and new ones include two of wax models prepared from cases of typhus. The publishers announce that a general index for the ten years 1915–24 will shortly be ready.

Sir Edwin Chadwick.

By Maurice Marston. London: Leonard Parsons, Ltd. 1925. Pp. 186. 4*s.* 6*d.*

In a small volume of 186 pages, one of the "Road-maker Series," Mr. Maurice Marston has retold, concisely and clearly, the story of Sir Edwin Chadwick's battling for reforms in sanitary and Poor-law administration during the mid-nineteenth century period. An account of his "life and doctrine" appeared in The Lancet in lecture form on April 19th and 26th, 1924, and it is unnecessary to relate at length the details of his contest for his "sanitary idea" against indifference, apathy, and even the actively hostile opposition of obscurantist and enraged bumbledom.

Mr. Marston, in seven chapters, traces the evolution of reforms in the Poor-law, in public health, and in the factory system, inspired by Chadwick, to the influence which the utilitarian radicalism of his master, Jeremy Bentham, had upon his apt and willing disciple. He claims that Bentham imported principle into legislation by creating a creed, and that while he overthrew paternalism he gave undue regard to *laisser faire*. We are not sure that the author's political predilections may not have gone too far in claiming that Chadwick, as Bentham's pupil, "connected individualism with collectivism" or the beginnings of socialism. Anyway, to Chadwick must be attributed the inauguration of central control and inspection in matters of sanitation, factory life, and Poor-law administration; and while the interests he offended and the incompetents on whose toes he trod hounded him from office in 1854, he survived till 1890 to see "the multitude make virtue of the faith they once denied," and to enjoy the encomiums of Lord John Russell, of Gladstone, of John Stuart Mill, of Florence Nightingale, and of the great Lord Shaftesbury. According to the last named, the antagonists of Chadwick included the Parliamentary agents, the civil engineers, the College of Physicians, the local authorities, the Treasury officials, the water companies, and the Commissioners of Sewers—a truly formidable combination. Yet the judgment of history is that of Sir John Simon, who, in his "English Sanitary Institutions," declares that the public health reforms of the early Victorian epoch were "directly due to the labours of one eminent public servant, Sir Edwin Chadwick." Having claimed his hero as a collectivist, an anti-capitalist, or even a socialist, the author, in his final chapter, calls Chadwick a "reactionary." The charge is based upon his attitude towards bacteriology; yet even the latest developments of that science are emphasising the potency of soil in relation to the seed, and the influence of environment in the warfare against disease. There is still much to be learnt from the old sanitarians, of whom Chadwick was the foremost and the greatest.

The book of Mr. Marston's is ably put together and forms a worthy addition to an attractive series of biographies. We think the author is mistaken in stating that Chadwick stood as a Parliamentary candidate for the University of London, and in 1848 he was made a Companion—not a "Commander"—of the Bath. It was not until a year before his death, at the age of 89, that he received the K.C.B. Recognition of his services was tardy and grudging, but all can agree with Mr. Marston that "now that we are in a position carefully to examine his work and his ideas it is possible to estimate how much gratitude the country owes to the man who left a profitable career at the Bar for an unremunerative position as administrator of reforms for the public welfare."

Elementary Morphology and Physiology.

For Medical Students. By J. H. Woodger, B.Sc., Reader in Biology in the University of London. London: Humphrey Milford. Oxford University Press. 1924. Pp. 528. 12*s.* 6*d.*

This useful and interesting volume differs from many handbooks for the commencing medical student by the wideness of its outlook—even psychological as well as anatomical and physiological—and by the comparatively small space assigned to the usual "types" and their structure. It can be read, therefore, by anyone possessing some knowledge of fundamental biology, as well as by the intending candidate for the preliminary scientific examinations at the outset of a medical career. The student must expect to have to study as well as this book one or more practical text-books such as the late Prof. Milnes Marshall's "The Frog," where all necessary details concerning that animal are to be found. With this warning the text-book before us may be recommended and, indeed, it needs no justification, so thorough is its elementary treatment of essentials. It may, perhaps, be a little difficult for the average beginner to read easily, but is well worth a little extra attention. A special feature of this text-book demands appreciative notice. The majority of the illustrations are original and have been drawn from the author's own preparations. Not only is this so, but other figures are from original sources and not mere replicas of well-known hackneyed illustrations.

Forensic Medicine and Toxicology.

Forensic Medicine. By Sydney Smith, M.D. Edin., D.P.H., Principal Medico-Legal Expert, Egyptian Government, Professor of Forensic Medicine in the Royal Schools of Medicine and Law, Cairo, &c. With an Introduction by Prof. Harvey Littlejohn, F.R.C.S. Edin., F.R.S.E., Professor of Forensic Medicine, University of Edinburgh. London: J. and A. Churchill. 1925. Pp. 498. 21*s.*

Lectures in Medical Jurisprudence. By William Nunan, B.A., M.D., Police Surgeon of Bombay, Professor of Medical Jurisprudence, Toxicology, and Mental Disease, Grant Medical College, Bombay. With an Introduction by Major-General A. Hooton, C.I.E., L.R.C.P., M.R.C.S., D.T.M., I.M.S., Surgeon-General with the Government of Bombay. Bombay: D. B. Taraporevala, Sons and Co. 1925. Pp. 162. 5*s.*

Works on forensic medicine and toxicology by authors who have practical experience of these subjects in the East are always welcome. India especially and many other Eastern countries afford excellent opportunities for the study of these subjects, not only as regards the quality of the material available, but also the quantity. Further, each country provides special problems from a medico-legal aspect, so that records in writing of various workers serve to broaden our viewpoint of the subject. Probably the total number of deaths from arsenic in this country in a year would not be more than 20–30, whereas the deaths in India alone number hundreds in a year.

The first of these books is a most valuable contribution to the literature of the subject. Dr. Sydney Smith has dealt with his subject thoroughly, but concisely, so that the volume is of moderate dimensions. The fact that he has drawn largely from his own experience serves to render the book more valuable, and the copying of obsolete and often inaccurate statements from other books is avoided. The volume may be recommended to students and practitioners in this country, for although most of his material has been collected in Egypt, the legal procedure pertaining to this country is recorded. The work is divided into 28 chapters and 5 appendices, of which 21 chapters are devoted to forensic medicine and 7 to toxicology. Of the appendices the two more important ones deal with chemical analysis and the examination of weapons and projectiles, and the final appendix discusses some of the special problems of forensic medicine which occur in the East. The book is profusely and helpfully illustrated. That the index gives only the principal reference to the various subjects is to be deplored, since often secondary references are important. Dr. Smith is to be congratulated upon a work which is a survey and a treatise. Prof. Harvey Littlejohn has written a graceful introduction in which he points out Dr. Smith's good fortune in the possession of a medico-legal institute. He expresses the pious hope that one day London will possess a similar institute under the auspices of the Home Office, where all the necessary experts are housed under the same roof. Such an institution would greatly aid the administration of the criminal law, and would be of special benefit to the medical student.

The writer of the second volume, Dr. Nunan, has not only had great experience of his subject, but, like Dr. Smith, has been called upon to teach the subject to students. This work represents the publication of his lectures and makes no claim to be a treatise on forensic medicine. To obtain a real insight into the subject it would be necessary to read between the lines to a considerable extent. The average length of a chapter or lecture is less than ten pages of ordinary octavo, and each could be delivered in some 30 minutes. The material here included is sound, but insufficient in detail, and it is probable that Dr. Nunan's students receive a good deal of extra information when he digresses from his manuscript. Many important medico-legal subjects are not touched on, such as rape, divorce, identity of dead, professional obligations, malpraxis, examination of seminal stains, &c. One or two misprints occur and a few rather more important errors, such as the description of hæmin crystals as being whetstone in shape, and the statement that the guaiacum test will produce a blue colour with no coloured substance except blood. However, in the main the material, as far as it goes, is sound and is simply expressed. Dr. Nunan has had extensive personal experience, and is evidently a careful worker. The book is without an index.

Medical Pathology and Therapeutics.

Traité de pathologie médicale et de thérapeutique appliquée. XXVII.: Diagnostics de Laboratoire. I.: Introduction, Méthodes Usuelles de Laboratoire appliquées au Diagnostic des Maladies. Par MM. les Profs. Letulle et P. Pruvost. Paris: A. Maloine et Fils. 1924. Pp. 730. Fr.60.

The appearance of this volume marks a further step towards the completion of the great series devoted to medical pathology and therapeutics now appearing under the editorship of Prof. Emile Sergent. Therein are considered the general principles involved in the investigation of disease by laboratory methods. Few details of technique are given; it may be the intention to include these in a further volume, for, as it stands, this volume contains insufficient in the way of technical detail to make it of service to the laboratory worker, while it comprises much that cannot be of great interest to the pure clinician.

In almost every section of the volume there is evidence that the author could not quite make up his mind for whom he was writing. Apart from this fundamental defect, it is an amazingly good work; no branch of laboratory diagnosis escapes the notice of the author and many of the sections are exceptionally good. This is particularly so in regard to a number of matters which are usually dealt with rather casually in English works—and for this reason the volume should be of particular use to British workers. Moreover, the author has a keen eye for the non-essential, and never includes matter merely because it has figured in books of the same sort in the past. Thus there are excellent sections on the anaerobes and the spirochætes, but only half a page is devoted to the staphylococci—after all, everything that matters about the staphylococci, so far as medicine is concerned, can easily be said in that space. One of the best sections is that devoted to the examination of the fæces; for some peculiar reason this particular line of investigation seems always to be more competently dealt with in French than in any other language. The section devoted to the examination of the blood by chemical methods serves to show the divergences between present-day French and English teaching in this respect. The very small extent of the section devoted to bacteriology will horrify that class of medical practitioners for whom the apotheosis of therapeutics is an emulsion of micro-organisms.

JOURNALS.

JOURNAL OF PATHOLOGY AND BACTERIOLOGY. Vol. XXVIII., No. 2. Pp. 133–396. April, 1925.—Experimental Soot Cancer, by R. D. Passey and J. Carter-Braine (London). An extract of soot consisting mostly of the ether-soluble bases is very efficacious in producing carcinoma of the skin in mice. Further fractionation of the preparation restricted the carcinogenetic factors to the higher boiling-point fraction.—The Influence of the Fat-soluble Accessory Food Factor on the Initiation of Soot Cancer in Mice, by R. D. Passey and J. L. Woodhouse (London). No perceptible effect.—Evidence that Anaerobes Tend to Produce Peroxide in the Presence of Oxygen, by J. W. McLeod and J. Gordon (Leeds). As in many experiments on the metabolism of bacteria, the quantities of substances involved are so small that it is difficult to reach certain conclusions, but evidence accumulates that anaerobes are anaerobic because they kill themselves with peroxide if oxygen is present. The peroxide is the natural result of bringing a reducing mechanism into relation with oxygen. All bacteria have reducing mechanisms of one kind or another; many protect themselves from the resulting peroxide by producing catalase as well.—Estimation of Urea in Blood by Hypobromite, by F. S. Fowweather (Leeds). Sufficiently accurate for clinical purposes as the author contemptuously says.—Factors Influencing the Flocculation Test for Syphilis, by H. F. Watson (Edinburgh). Fresh heated serum must be used and the results are obtained more quickly if the tubes are shaken.—Arthritic Muscular Atrophy, by A. E. Beryl Harding (London). The acute wasting of the relevant muscles in arthritis has always been something of a mystery; it certainly cannot be explained by disuse alone. The condition can be readily reproduced in rabbits in which an arthritis has been achieved by chemical trauma followed by streptococci.—The Growth of Branching Forms of Bacilli, by A. D. Gardner (Oxford). Long branching Y-shaped forms are found in the stage of rejuvenation of many bacilli (*B. coli*, typhoid, dysentery, cholera, &c.); they grow into normal bacilli at all three free ends simultaneously.—Adenomyoma of the Stomach, by M. J. Stewart and A. L. Taylor (Leeds). See THE LANCET, April 18th, p. 830.—The Investigation of Phytopathogenic Bacteria by Serological and Biochemical Methods, by R. St. John-Brooks, K. Nain, and Mabel Rhodes (London). The curator of the National Collection of Type Cultures has investigated a number of described species of bacteria supposed to cause plant diseases by the methods familiar to the human pathologist. They are readily grouped by these tests; some species fail to establish their individuality.—The Correlation Coefficients of the Urine with Special Reference to Cancer, by C. Powell White (Manchester). Nineteen quantitative determinations on each of 100 samples of urine, 50 from cases with and 50 from cases without cancer, provides the material on which the author exploits what seems to be a novel method of trying to find out which constituents of the urine are excreted together. Statistical crude and partial correlations show, e.g., that sodium and chlorine are associated with water while sulphate is not, that urea is correlated chiefly with creatinin, phosphoric acid, and potassium, &c.—The Renal Circulation Rate in Experimental Oxalate Nephritis, by J. S. Dunn, J. H. Dible, N. A. Jones, and B. A. McSwiney (Manchester). Within normal limits by the technique used.—Diphtheria Antitoxin in the Blood of Normal Horses, by A. T. Glenny (Beckenham). Many horses, but fewer in recent years, which have never been immunised show a certain amount of antitoxin in their blood, are resistant to comparatively large doses of toxin, and produce antitoxin exceptionally well; the source of infection has not been traced.—The Relation Between Dosage and Death Time, by A. T. Glenny (Beckenham). With diphtheria toxin the relation was found to be: (log no. of M.L.D.) (time in hours −10) = 12.—The Time of Combination of Diphtheria Toxin with Living Tissues, by A. T. Glenny and Barbara E. Hopkins (Beckenham). A Schick dose of toxin given intradermally will produce its effect even if 10,000 times its equivalent of antitoxin is injected intravenously 15 minutes later.—The Antigenic Effect of Intravenous Injection of Diphtheria Toxin, by A. T. Glenny and C. G. Pope (Beckenham). More effective than has been supposed.—The Combining Power of Diphtheria Toxin and Toxoid with Antitoxin in Relation to their Antigenic Efficacy, by A. T. Glenny, C. G. Pope, and Hilda Waddington (Beckenham). The authors traverse much classical ground in the light of recent knowledge of skin testing by Schick's method and of Ramon's method of in vitro titration of toxin and antitoxin. The flocculation method gives for the first time a measure of the combining power of a mixture of toxin and toxoid, and it is this that has the nearest relation to antigenic value. Toxin made almost atoxic by treatment with formaldehyde is highly efficient in causing an animal to produce antitoxin.—The Effect of Serum-Sensitiveness and Precipitin Formation on the Efficacy of Diphtheria Toxin in Promoting Antitoxin Production, by A. T. Glenny, Barbara E. Hopkins, and Hilda Waddington (Beckenham) is dealt with editorially in our present issue.—The Titration of Diphtheria Toxin by the Flocculation Method, by A. T. Glenny and U. Wallace (Beckenham). The fact discovered by Ramon that mixtures of diphtheria toxin and antitoxin flocculate at the neutral point makes it possible to evaluate the strength of a toxin or antitoxin in a few hours without using any animals. In some cases a second zone of non-specific flocculation occurs.—Immunological Notes with Special Reference to Diphtheria Toxin and Antitoxin, by A. T. Glenny, C. G. Pope, Hilda Waddington, and U. Wallace (Beckenham). Individual guinea-pigs vary a good deal in their response to an antigen; young animals are less readily immunised than older ones and the route of injection and dilution of the injecta make differences. The antigenic power of toxin modified by formalin to the atoxic condition is improved by the addition of traces of fresh toxin. Modified toxins retain a little of their antigenic power after boiling. Very small doses of toxin may satisfactorily immunise a guinea-pig.—Group and Specific Agglutination, by F. W. Andrewes (London). The author showed previously that cultures of organisms of the Salmonella group consist of two sorts of bacteria sharply distinguishable by their agglutination reactions; in the one specific properties predominate, in the other the properties of the generic group. By absorption tests he now confirms this distinction and measures the amounts of the two agglutinable substances; in the group phase the specific element may be about 1 per cent. of the whole, in the specific phase the proportion of group elements may be even less. The facts are of fundamental importance in the identification and classification of bacteria by these methods.—The Pathological Classification of Goitre, by G. Scott Williamson and Innes H. Pearse (London). A new classification and interpretation of the various anatomical derangements of the thyroid, based on the authors' views of the structure of the gland and its functional changes, which cannot be summarised; all interested in the thyroid should study the original. —Ruptured Aneurysm of the Basilar Artery at Age 17, by J. B. Duguid (Aberdeen). Arteries apparently normal, no syphilis.—Unusually Large Cardiac Aneurysm, by T. Shennan (Aberdeen).—Case of Multiple Cystic Liver, by C. R. Burns (Otago). Without the usual cystic disease of the kidney.—Carcinoma of the Jejunum, by P. P. Lynch (Otago).

THE NATIONAL PHYSICAL LABORATORY.

The report of the National Physical Laboratory for the past year is a volume of 220 pages devoted mainly to accounts of the researches in progress at the laboratory. The opening pages contain the report of the Executive Committee, which is a general survey of the work undertaken and indicates lines of future investigation. It states that the past year has been one of good work and progress. Work for the Service Departments has been maintained on approximately the same scale as in previous years, while there has been an increase in the tests and investigations undertaken for business firms. The need for new buildings has again been pressed. Obviously the pressure of external requirements should not be allowed to interfere with the fundamental research and standardisation work of the laboratory, and it is therefore gratifying to note that the erection of a portion of the new Physics Building will begin this year.

Work in Various Departments.

The main portion of the volume is devoted to the reports of the various departments of the laboratory. These deal with researches and tests in all branches of physical science. The report of the superintendent of the Physics Department, Dr. G. W. C. Kaye, is perhaps of more immediate concern to the medical profession. The number of clinical thermometers tested was 698,665, a slight increase on the figure for the preceding 12 months, the quality of the instruments being well maintained. It was found that thermometers made of soda glass were more likely to develop defects than those constructed of lead (or Jena) glass, and a clause specifying the nature of the glass used for clinical thermometers has therefore been inserted in the regulations. A quick and simple method of distinguishing between soda- and lead-glass instruments is by X ray examination.

In the *radiology* section the number of radium preparations tested was 111, whilst protective materials dealt with numbered 155. It has been necessary to duplicate the apparatus for testing, by the alpha-ray method, the feeble radio-activity of mineral waters and low-grade ores. The number of X ray installations examined was 30 as against 27 for last year. The X ray departments of a number of hospitals have been inspected, and a marked improvement in the construction and in the protection afforded by new X ray apparatus is recorded. Research work is being continued on the all-metal vacuum pumps. It is hoped to modify the annular jet pump with a view to its operating against higher back pressures than 1 mm., a disadvantage in the existing models. In parallel with high vacuum research, preliminary experiments with large cathode X ray tubes have been carried out to determine the design of an X ray tube capable of taking heavy currents and of withstanding increased potentials. A research on the absorption and scattering of gamma rays has been carried out under the direction of Dr. A. E. Owen. Additional standard radium solutions have been made and data have been obtained regarding the absorption of gamma rays and the corrections which have to be applied to the observed radium content of radio-active solutions when measured by the gamma-ray method.

The work on *X ray protection* in association with the X Ray and Radium Protection Committee has been continued. Tests to determine the variation of the lead equivalent of protective materials with the wave-length of the radiation have been made. It was found that whilst the variation was inappreciable for lead glass and lead rubber, it might be considerable for materials such as barium plaster, and the report lays stress on the importance of stating the voltage at which the lead equivalent of a protective material is required.

Dr. Kaye reports that a considerable amount of work has been completed in connexion with *hygrometric measurements*. At the instigation of the Food Investigation Board, the behaviour of various materials when used as substitutes for hair in hygrometric instruments has been studied. An apparatus has also been constructed in the department for producing an air stream of a definite humidity, based on the fact that the aqueous vapour pressure over a solution of calcium chloride is a function of the concentration. The widespread interest in humidity control may be gauged by the fact that the department had inquiries for information from the industries of cotton, woollen, silk, tobacco, laundry, chocolate and confectionery, leather, fruit and egg storage, fish preservation, and mining.

Research in *sound* has been somewhat hampered by the lack of adequate accommodation. Nevertheless, progress has been made and preliminary measurements on the acoustic absorption of large-scale specimens have been carried out. The technique has been mastered of the photography of sound by the spark method and of water waves by the ripple tank method, the latter having already been used in connexion with the designs of the proposed new Parliament House at Belfast.

The *Electricity* Department, working in conjunction with the Industrial Fatigue Research Committee of the Medical Research Council, have carried out experiments to determine the relation between illumination and the accuracy and speed of working portions of linotype machines and of compositors' frames in a large printing works. The preliminary investigation showed that experiments cannot be conveniently carried out under actual working conditions, and it is proposed to undertake an investigation under laboratory conditions.

Research work for the *Dental Research* Committee of the Department of Scientific and Industrial Research has been continued in the Metallurgy Section. The alloys of the silver-tin system have been investigated and the results show that the constitutional diagram previously published for these alloys is incorrect. A beginning has also been made with the study of the silver-mercury system, dealing in the first instance with alloys rich in silver.

Projected Extensions.

Plans for the building and equipment of a high voltage laboratory have been developed and tenders have been invited. The proposal is to build a plant capable of giving 600,000 volts three-phase and 1,000,000 volts single-phase current. The behaviour of the newly erected plant for 1,000,000 volts in Paris has been of material help in coming to a decision as to the size of building necessary for the purpose. In the scheme of research for the present year, the Electricity Department will make measurements of very small amounts of power, one watt or less at several thousand volts, and comparison of the different methods of carrying out such measurements will be made. Work on the use of water resistances in the attempt to obtain reactance-free resistors, especially for high voltages, is also contemplated. For those using X ray plants the results of these investigations will probably be of considerable value.

The reader will find the report sufficiently detailed to allow him to understand the object of the various researches, the methods adopted, and the results so far obtained. The volume is indeed a valuable contribution to scientific literature.

For Infant Feeding

Horlick's Malted Milk—the Original—supplies all the elements of nutrition in Cereals and Milk in proper proportions and with the amylolytic conversion of starch, thus fulfilling the physiological requirements of Infants and constituting the characteristics of a proper diet in Infancy. It is dependable in all climates, free from pathogenic organisms, and affords a solution to the pure milk problem, as well as the prevention of those diseases often induced by amylaceous foods. Complete in itself and ready in a moment by briskly stirring the powder in water only.

Liberal samples free to Members of the Profession.

To secure the original, always specify HORLICK'S.

INTENSIVE PROPHYLAXIS
AGAINST

Hay Fever

MANY patients who are subjects of hay fever wait until almost the onset of the season before the question of inoculation against the disease is considered.

In order to deal with such cases an intensive prophylactic course is recommended, experience having proved it to be distinctly useful. Furthermore, it is a great advantage to be able to carry out a more or less complete prophylactic course extending over a fortnight only. A "safe" initial dose of "Pollaccine" is given in the first instance, usually between 10 and 100 units, preferably determined by the specific ophthalmic or cutaneous reaction, although, bearing in mind that the hay fever patient of average sensitiveness requires 50 units, these tests can often be dispensed with. The doses are repeated every day, or every other day, according to circumstances, and are increased by 50 to 100 per cent. each time, unless there is any contra-indication. If there is a reaction from any dose this will take place within a few hours, and may take the form of headache, urticaria, slight asthma, or general malaise; should this occur the succeeding dose must be either the same or smaller, according to the intensity of the reaction, and thereafter the increase in dose should be more gradual. In this way the dose may reach 500 units, or even more, although a point beyond which the dose cannot be increased without symptoms may be reached before 500 units can be safely injected. In any case, it should be the object of the physician to conclude the treatment before the expected commencement of hay fever.

Should any reaction be particularly severe it can be controlled by the injection of 5 minims of Adrenalin Chloride Solution.

Details of the treatment will be sent on application.

"POLLACCINE" is an extract from the pollen of Timothy grass prepared in the Inoculation Department of St. Mary's Hospital, London, W. (Director: Sir Almroth E. Wright), and supplied in various dilutions. Further particulars will be sent to physicians, on request, by the Sole Agents:—

THE LANCET.

LONDON: SATURDAY, MAY 9, 1925.

THE ISSUES BEFORE THE ROYAL COMMISSION ON HEALTH INSURANCE.

THE mass of evidence already laid before the Royal Commission on National Health Insurance is enormous—it is stated to exceed one million words—and it has been our care to summarise this evidence from week to week for the information of our readers. Certain broad issues are emerging, and a note on these may appropriately appear at a time when the representatives of the medical profession are giving their evidence before the Commission. The printed statement which Dr. R. A. BOLAM and his colleagues are expounding to the Commission is given in a very condensed form on another page. The emphasis and amplification of that statement, as Dr. H. B. BRACKENBURY reminded the members of the conference held at Westminster on March 12th, must be entrusted to those who sit in the witness chair and answer the questions of members of the Commission. We hope in due course to give a résumé of the oral evidence so taken. It is in any case important to remember that the proposals on behalf of the profession, considered as a whole, are rather an indication of the lines on which a national health insurance scheme should go forward than a suggestion that they are immediately practicable, financially and administratively.

Let us deal first with the big question whether the dependants of the insured are to be dealt with under an insurance scheme. The evidence of the approved society witnesses fails to reveal any clear demand for such a drastic step at the present time, although the principle receives a very wide blessing, and it is felt that the dependants are not receiving adequate treatment—a fact which more than one of the speakers at the conference of medical representatives was prepared frankly to recognise. Opinion in the medical profession on the question of the inclusion of dependants in the insurance scheme is divided, with the result that the evidence on their behalf is in the nature of a compromise. No one is likely seriously to quarrel with the first fundamental principle set out in that evidence that the medical provision under the National Health Insurance Acts should be available only for those persons who would be unable to obtain it without the help of the insurance scheme. And it is well to let it be known, through the Royal Commission, that, in conformity with that principle, the general practitioners of the country are prepared to provide a medical service for the dependants of insured persons below a certain income limit. But, frankly, it seems to us that the application in practice of an income limit for manual workers, who constitute the vast majority of the insured population, is full of the difficulties which were set out by Mr. E. B. TURNER at the conference to which we have referred. These difficulties were, we believe, felt to be insuperable in 1911, and there is little reason to suppose that the authorities would find them any more ready of solution at the present time. The Insurance Acts are hardly likely to be revised so as to apply an income limit to the insured persons themselves when they are engaged in manual labour, and the question, so far as the dependants of the insured are concerned, will almost certainly, therefore, be found to be that of treating all or none. A scheme for the treatment of all the dependants at the present time is not, we believe, within the region of practical politics.

Witnesses before the Royal Commission have been very definite in deprecating any increase in the weekly insurance contributions, and any remote possibility of such a step for purposes of health insurance developments has disappeared with the introduction by the Government of a contributory scheme of pensions to include widowed mothers and orphans. Developments under the National Health Insurance Acts must, therefore, be found within the existing finances of the scheme. The valuation results which have been recently declared show, we are given to understand, surpluses considerably exceeding those which were revealed in the 1918 valuation. The societies which are fortunate in the enjoyment of these large surpluses have been unanimous in displaying reluctance to any system of pooling, whereby the less fortunate societies can participate in the additional benefits which will flow as a result of these surpluses. The objections of these societies to pooling arrangements can quite well be understood in view of the emphasis which was laid in 1911 on the opportunity which societies would have in selecting members, and on the facilities which would be afforded to insured persons to join societies for their own particular trades and occupations, and generally to enjoy freedom of choice in the selection of societies. Moreover, the societies were to enjoy the fruits of their good management. He would be a particularly bold man who would claim as due to good management the very substantial surpluses now being declared. Societies, presumably recognising that there are other factors in the situation, have in most cases intimated their willingness for some extension of the scope of medical benefit to be of a national character, a portion of the funds being set aside for this purpose, thus in effect reducing the possibility of large future surpluses. The new benefit for which there is almost an insistent demand is a national scheme of dental treatment. It will appear from the evidence of the British Dental Association and other dental bodies, which we shall shortly publish, that the dentists feel equal to maintaining a national service. Inasmuch as there is great force in the argument that a service which would leave a large part of the dentist's bill to be met by the patient would fail just where the most needy members of the community are concerned, nothing less than a complete service free of cost to the patient could well be considered by the authorities. The estimates of the cost of such a service, which vary from 5*s.* to 6*s.* 6*d.* per insured person, seem to be based on a wholly insufficient volume of experience. In particular, the suggestion in the British Dental Association's evidence that the demand rate would appear to be 5 per cent. of the persons entitled to the free treatment appears to us to be quite inadequate when considered in conjunction with the picture which is drawn of the unsatisfactory state of the mouths of the people of this country. It may well be that an extension of medical services in the direction of consultant and specialist treatment and the provision of clinics and laboratory facilities for all of which there is a substantial, though secondary, demand from those who speak for insured persons, may prove much more susceptible of realisation than the more costly scheme of dental benefit. The inclusion of antenatal and maternity services within the scope of medical benefit to the extent recommended in the evidence of the medical profession should also be capable of realisation within the limit of the funds available.

Reviewing the position as a whole, we are forced to the conclusion that until the official witnesses are again before the Commission to demonstrate, as we presume they will be called upon to do, which of the numerous proposals are possible of fulfilment, judgment must to some extent be suspended. We may at least, however, congratulate the medical profession on having their case so skilfully handled as it is in the document which is being expounded this week to the members of the Royal Commission. For the rest, as we have said, we must wait for some further indication of what is financially and administratively practicable, and the official evidence, at least, is likely to be prepared in the fierce light and the chilling atmosphere of finance.

THE RECEDING CHIN.

Orthodontics, or the treatment of irregularities of the teeth and jaws, is a comparatively modern development of dental science. It has made great strides and is attracting an increasing amount of attention from dentists. Much ingenuity has been devoted to the construction of delicate appliances for correcting irregularities of the teeth. Much attention has been given to the many complex factors concerned in the ætiology and pathology of irregularities of the teeth and jaws. The type of irregularity associated with the receding chin is characteristic and easily recognised. It is customary to group irregularities of the teeth in accordance with the deviation from the normal occlusion of the teeth when the jaws are closed. The normal occlusion is such that each tooth interdigitates with two other teeth in the corresponding jaw. Thus, the lower first molar normally meets both the upper first molar and the upper second premolar, and so on. In effect, all the mandibular teeth are slightly in advance of the corresponding upper teeth. The typical superior protrusion of the upper incisors and canines, which is accepted as the customary English type in the Continental comic papers, is generally associated with a normal molar occlusion. In contradistinction to this type of irregularity, there is a class of malocclusion in which the lower molars are posterior to their normal position. The lower first molar instead of meeting the upper molar and second premolar, meets the upper first molar and the anterior third of the upper second molar. Varying degrees are met with, but such a degree may be taken as the average extent of this irregularity. The remaining anterior teeth share in this displacement, with the result that the lower incisors instead of being just behind the upper incisors, occupy a place much posterior to the normal. This gap becomes accentuated by the lower lip getting behind the upper incisors and pushing them out. To a casual glance such a case may seem to be typically one of superior protrusion, but a closer study will reveal the fact that it is the lower jaw which is primarily at fault. The displacement of the lower teeth is not a local irregularity of the teeth in a normal mandible, but is due to a defect of growth of the bone itself. Since the chin is merely the anterior end of the mandible, together with its superficial soft tissues, it follows that in these cases the chin shares in the lack of growth and is on a plane posterior to the normal, thus giving to the facial contour that appearance of a receding chin which is popularly associated with feebleness of will-power. Technically, this irregularity is known as "post-normal occlusion," while in recognition of the fact that it is primarily a defect of mandibular growth it is often spoken of as mandibular retrusion.

Irregularities of the teeth are common and appear to be much on the increase. Of the various types of malocclusion, post-normal occlusion represents a considerable percentage of the cases met with in dental practice. The ætiology is obscure. A view which held ground for a long time, and still has its adherents, is that it follows on nasal obstruction which, in its turn, is chiefly due to adenoid vegetations. Latterly, there has been a tendency to seek its cause in some more deeply-seated defect of growth occurring at a much earlier period of life. A. Keith and G. G. Campion[1] have suggested that both defective growth of the jaws and adenoid vegetations may alike be the expression of some deficiency of endocrine secretion. R. W. Weinburger[2] has suggested that the irregularity may be due to some antenatal condition. Certain it is that the irregularity may occur very early in life, long before the permanent teeth come into place, and when the mechanical effects of nasal obstruction could hardly become operative. Considerable success has been attained in its treatment, with results which are not only apparent in the arrangement of the teeth, but also in the alteration of the facial profile. By means of a special kind of plate it is possible to throw the lower jaw forwards so that the molar teeth meet in their proper position. At first only a habit of biting forward is induced, but gradually the new position becomes an anatomical one until a time arrives when the individual can no longer cause the teeth to meet in their original position. The sequence of changes which occur in bringing about this result have not been fully worked out, but it seems probable that actual changes occur in the ascending ramus and condyle. Such a result cannot be guaranteed in every case, but in a sufficient proportion of cases the improvement in appearance is so gratifying as to make the attempt well worth trying.

Since the handicap of resting under the stigma of weakness of character because of this defect of bone growth is very real, there is an additional reason for trying to remedy this irregularity of the teeth. Indeed, the social and economic aspect of post-normal occlusion may be more important than the purely dental aspect and affords, perhaps, the strongest justification for undertaking treatment. The individual of strong character, or who is favoured by fortune, may be able to survive the handicap of a receding chin, but to many a lesser person it must often prove a real hindrance in the stress of competition. Though it would seem highly irrational to correlate weakness of will with this physical defect, it would be rash to assume that there is nothing in this popular prejudice. Just as the adenoid child is thought to be stupid because he is deaf and eventually, because he is neglected, may actually become stupid, so the individual with post-normal occlusion, being regarded as weak, is treated as such and may end up by becoming what his fellows assume him to be. It is conceivable that if the view of Keith and Campion is correct, that the condition may represent an endocrine deficiency, there might be a true correlation of mental defect due to the latter condition. Perhaps the true explanation of the widespread impression may go back to the beginnings of civilisation. The prognathism of primitive man and his ape-like forbears carried with it an appearance of ferocity. In time, as man became more civilised, this impression of animal power associated with massive jaws became transmuted into an impression that a strong jaw represented strength of will and decision. It can be easily understood that the opposite condition of a receding chin should be assumed to represent an absence or diminution of those virile qualities of mental decision which unconsciously we have come to associate with a strongly marked chin.

INTERFERENCE IN IMMUNITY RESPONSES.

BY the laws of chance and human good fortune a man seldom has two infectious diseases simultaneously. But one attack by a parasite generally leaves his apparatus of immune response in a condition which is different from its natural state in the sense that it is more facile and more easily roused to action by a second invasion; the effect of one infection, in short, may last till he is subjected to a different one. And to have two infectious diseases at different times is very common. The question of their influence on one another has been a good deal debated and in general along two lines of thought. On the one hand, it is possible that an immunity mechanism which has had experience and practice in responding to, e.g., the typhoid bacillus, will, when subsequently stimulated by, e.g., the paratyphoid bacillus, respond better than it would if it had never experienced anything of the kind before. And how far the first antigen would influence the response to the second would presumably vary with their relationships; close alliance, such as typhoid and paratyphoid, would probably influence the second response favourably, while remote similarity, such as typhoid and diphtheria, might well be without any result. There are many animal experiments which show that this is so and non-specific immunisation can be realised in a variety of ways. In human experience there appear to be no quite clear facts, but the general resistance of urban, as compared to rural, populations when exposed to the same infections under the same conditions illustrates the same phenomenon. On the other hand, we have to consider what would happen if the body is stimulated simultaneously by two antigens. If the two are sufficiently unrelated, we should expect little or no mutual influence, on the assumption that the mechanisms aroused are not the same. But if the two stimulate the same cells in the body it might well be that the tissues, especially at a first attack and in an untrained state, might fail to respond as well to each as if they had had only one to cope with at a time; in other words, the two antigens might interfere with one another. Such interference is known with typhoid-paratyphoid vaccines compared with preparations containing typhoid bacilli only, though whether it is of any practical moment is doubtful, and an interesting case of interference between antigens which are seemingly more dissimilar than these bacilli is described by Dr. A. T. GLENNY, Miss B. E. HOPKINS, and Miss H. WADDINGTON in the last number of the *Journal of Pathology and Bacteriology* (vol. xxviii., p. 305). If a rabbit is injected with horse serum it forms horse precipitins in its blood; if it is injected with a mixture of diphtheria toxin and horse antitoxic serum it forms diphtheria antitoxin; if it receives the toxin-antitoxin mixture while it is forming precipitins in response to an injection of normal horse serum it fails to produce antitoxin. It might be thought that this was due in some way to both the injections containing horse serum, that the precipitin perhaps carried out of action the antitoxin and with it the toxin and the stimulus. That this is not the explanation is shown by the fact that if a rabbit is responding actively by precipitin formation to an injection of cow or goat serum, it equally fails to respond to a toxin-horse-antitoxin mixture by antitoxin production. Non-toxic preparations of diphtheria toxin act as good stimuli in rabbits by themselves without any mixture of antitoxic serum, but these toxoids are without effect in animals which are producing precipitin to horse serum. Presumably, therefore, the whole attention of the mechanism of response may be occupied by one antigen, and there will be no effective excitation if a second comes along at that time. It would presumably be a bad thing to catch diphtheria and tetanus within a few days.

◆

FORECASTING THE MENTAL DEFECTIVE'S CAREER.

ONE of the responsible tasks falling upon certifying officers of special schools for the mentally deficient is that of estimating the probable future social adaptability of the children, and in particular the occupations for which they may be suited. In his presidential address, now reprinted, to the School Medical Officers' Group of the Society of Medical Officers of Health Dr. J. W. Fraser, of Hull, describes an interesting investigation he has carried out to determine "the value of intelligence tests in the prognosis of the future careers of mentally defective children." Four groups were distinguished—those employed and earning more than £1 per week, those earning less, those unemployed, and those in institutions. His figures show no definite evidence of relation between the intelligence quotient calculated at any one age and the after-career, but where the quotient was calculated for several years in succession, some relation has been established between its fluctuations and the after-history. Dr. Fraser is not unmindful of the fact that intelligence is by no means the only factor in success, but his conclusion, shortly summarised, is that in the case of boys, where there has been an average annual gain of half a year in mental age and a terminal intelligence quotient of 50 or more, if the character is stable, and there is some manual capacity, the prognosis for the future is fairly good. In the case of girls the figures are inconclusive because so many girls were kept at home and had to be reckoned as unemployed. Success in the case of boys was found to be more sure if they were allowed to leave at 14, and in the case of girls retention at school until 16 was a fatal bar to employment at a remunerative occupation. It may, of course, be suggested that it is usually the best cases who are released from school attendance at 14, the cases, therefore, who are more fitted for employment; but it is well known to all certifying officers that the retention of children in special schools until 16, which is legally compulsory, is a handicap against their obtaining employment, and it can only be justified where there is definite provision for older scholars in trade schools, which should preferably confer no stigma of deficiency upon their pupils. Dr. Fraser was much impressed by the fact that only 7 per cent. of his cases were earning enough to keep themselves, and very rightly urges the importance of the provision of more institutions in which each inmate should carry out profitable work proportioned to his capacity.

THE LATE SIR CLIFFORD ALLBUTT'S BEQUESTS.—Sir Thomas Clifford Allbutt, Regius professor of physic in the University of Cambridge, left estate of the gross value of £56,963. His will contained the following bequests: to the Fitzwilliam Museum, Cambridge, his portrait by Sir William Orpen, and on the death of his wife a quantity of antique furniture and drawings and paintings by noted artists, including Landseer, Crome, Romney, Rossetti, G. F. Watts, J. M. W. Turner, and Fripp; to Gonville and Caius College, Cambridge, three silver and gilt drinking horns or cups (known as Swedish cups), requesting that his name as donor should be engraved thereon; and, subject to private bequests, the ultimate residue of his property to Gonville and Caius College, Cambridge, for Clifford Allbutt Fellowships for medical research or otherwise for the benefit of the said College in the discretion of the Master and Fellows, provided that no part thereof be used for building; £50 each to the British Medical Benevolent Fund and the Medical Charitable Fund for the West Riding of Yorkshire.

Annotations.

"Ne quid nimis."

THE BATEMAN APPEAL.

WE have kept this appeal open because subscriptions have continued to come in, but they are arriving only by driblets, as will have been seen by the acknowledgments. We hope that before closing the appeal some total will be reached signifying to a more marked extent that the medical profession have realised how vitally important to their interests the revision of Dr. Bateman's sentence was. Dr. Bateman was found by a jury to have been guilty of malpraxis meriting a term of imprisonment. When the account of the case was published in THE LANCET it became evident that the issues had not been properly put before the jury, for such tragedies were known to have occurred previously with no question of malpraxis arising, while due value had not been given to the testimony of clinicians. The sentence was accordingly quashed. For the medical profession at large the situation was now seen to have been an extremely serious one, implying that a practitioner in the course of his duties might be involved in a trial where the verdict will lie in the hands of persons quite unable to appreciate what has happened. This is the situation in which Dr. Bateman found himself, while his extrication from it has left him a sorely damaged man. The costs of the appeal were largely defrayed by THE LANCET, and only a small further sum has been received as yet to indemnify him for the loss of practice, to say nothing of his mental anguish.

JEJUNOSTOMY FOR PERITONITIS AND OBSTRUCTION.

IN THE LANCET of April 25th we published a paper by Mr. Seton Pringle in which he advocated jejunostomy in certain cases of diffuse peritonitis. This paper was read before the Royal Academy of Medicine in Ireland and gave rise to an interesting discussion. Jejunostomy is a measure which has been employed for some considerable time now, but has never received very general recognition or been practised extensively, yet it would appear to be a valuable method of treatment in properly selected cases. Patients in whom the operation is particularly called for are those suffering from diffuse pelvic peritonitis, where the inflammatory process affects two regions of the alimentary canal—the pelvic colon and the pelvic coils of ileum. The result is that there is set up a paralytic ileus in the two places concerned. Mr. Pringle believes that the onset of death is accelerated by absorption from the distended bowel above the obstructed areas, especially by the absorption of toxic substances in the small intestine. If these can be drained away from the body, the natural immunity reaction of the patient may be just sufficient to pull him through. He therefore advises that when the abdomen is opened and serious diffuse pelvic peritonitis is found to be present, a high enterostomy above the level of the umbilicus should be performed as a primary procedure. In the past many surgeons who have adopted enterostomy as an adjuvant measure have performed it only when, after the original operation, the patient's condition has become progressively worse. Under these circumstances it is frequently found that the enterostomy does not drain away the intestinal contents, or only begins to do so after two or three days if the patient survives this period, when the need for such evacuation no longer exists. The operation under these circumstances has been performed too late, for the paralysis of the pelvic coils of the intestine has extended upwards to the previously unaffected regions. It would seem quite clear that jejunostomy, if it is to be performed in such cases, should be done at the first operation. It would certainly seem a method more advisable than the ileo-colostomy with cæcostomy recommended by Mr. Sampson Handley. This latter is rather a serious intervention in a patient suffering from such a grave illness.

The advisability of performing jejunostomy for intestinal obstruction is not so evident. Advocates of the method declare that lives will be saved by performing a jejunostomy through a small laparotomy wound without exploration of the abdomen in late cases of intestinal obstruction. Series of cases have been published in support of this view. Jejunostomy is certainly a valuable therapeutic measure when the obstruction is due to a local peritonitis, such as occurs after appendicitis, but it is doubtful whether it could be carried out in a large number of cases of mechanical obstruction, such as that by band, without disaster occurring. The danger run is that the constricted portion of intestine may become gangrenous and perforate into the peritoneal cavity. Although it is true that once obstruction is relieved by jejunostomy there is a tendency for the congested gut at the site of the obstruction to shrink and so be relieved from pressure, yet it would seem too risky to rely upon this as an invariable issue. In the discussion on Mr. Pringle's paper several surgeons related their experiences of the operation, and the general conclusion was that in early cases of septic pelvic peritonitis jejunostomy was a valuable therapeutic adjunct, but that when the inflammation had spread upwards to the abdominal cavity results were not likely to be good.

THE ROYAL ACADEMY.

THE 157th exhibition of the Royal Academy of Arts was opened to the public on Monday last and provided a large number of beautiful things for inspection. And these things are of high level, well arranged, and well hung.

We believe that there is no doubt among those whose official business it is to know that achievement in landscape painting has become definitely of a higher standard and of more varied scope in this country during the last 20 years or so, and there are notable pictures in this exhibition by Mr. George Clausen, Mr. Arnesby Brown, Sir D. Y. Cameron, Mr. Lamorna Birch, Mr. Rex Vicat-Cole, and Mr. Philip Connard which would do honour to any collection of contemporary art. It must also strike an ordinarily observant visitor, as presumably it has struck expert critics, that our general sense of colour as a nation has become larger and truer. Time was when the general idea, for example, of the colour of a nude was that it should be pink or brown, according as to whether the subject was young or old, fair or swarthy; and even in medical journals we have seen some ridicule expended upon that real vision of the artist which was attempting to bring before our eyes the infinite number of direct and indirect tints, reflections, and gradations which are revealed on the bare surface of the body, when subjected to the influences of environment. The man who should now suggest that a green shade suggested putrescence would not be thought funny; everyone would know that he was merely convicting himself of a lamentable lack of observation, and he would have the public against him instead of for him. We have learnt in recent times to see with far more accuracy, and to identify as the truth what we were wont to consider pictorial fallacies. Indeed, we can imagine visitors to the exhibition this year finding that in certain canvases the artists have given us what they think is as much as we are likely to be able to appreciate, and have to that extent defaulted from the real.

The medical portrait is a frequent feature at Academy exhibitions for obvious reasons. A fair number of medical men attain to official positions when a presentation portrait becomes inevitable, and having done so, they have generally acquired the right to wear robes of a sort which by themselves would compel the artist to take an interest in the work. There are, however, this year only two or three pictures which come under the category. Among them is a portrait of Dr. Matthew Hay, by Mr. Charles Sims, one of Sir Humphry Rolleston, by Mr. George Henry, and one of Sir Donald MacAlister, by Mr. Maurice Greiffenhagen. The portrait of Dr. Matthew Hay is on the wall that bears the Sargent portrait of the Marchioness Curzon and Sir William Orpen's cryptic "Man versus Beast." The subject wears scarlet and puce robes to which the artist, as a brilliant colourist, has done full justice. The rather fixed gaze of the eyes is open to criticism, but it is a striking performance. Mr. Henry's presentation of Sir Humphry Rolleston is quiet and dignified. It is essentially a pleasant picture. A characteristic expression of the subject has been faithfully rendered, and the general effect of the dark blue robe is restful and yet important. Of a very different category is the portrait of Sir Donald MacAlister. This is a genuine *tour de force* in reds, only the face being shown and the shoulder line swathed in the scarlets and pinks of the Doctor's gown. The face is presented to us absolutely full, and the colouring is almost harsh in its boldness, while not a stroke has been inserted that does not in some way help to bring out the force and intellectual ability of the man. The picture has, of course, been painted by an artist who has had every opportunity of knowing his sitter personally; it is not entitled "A Presentation Portrait," and many would like to know what is to be its destination.

ARTIFICIAL UNILATERAL PHRENIC NERVE PARALYSIS.

THE difference between artificial and "natural" unilateral phrenic nerve paralysis is like that between an artificial and a "natural" pneumothorax. The artificial lesions are almost painless and free from discomfort, whereas when morbid conditions cause either phrenic nerve paralysis or a pneumothorax, the patient is in a parlous state. It is interesting to note in the paper published by Sir Charlton Briscoe in THE LANCET of Feb. 21st, that he finds that "most patients with phrenic paralysis are too ill for prolonged examination, and cannot tolerate the supine posture for any length of observation." The question may be raised: Is the phrenic paralysis per se or are the morbid processes causing pressure on the phrenic nerve responsible for the patient's critical condition? It is noteworthy in this connexion that artificial paralysis of one phrenic may not only fail to embarrass the patient, but may even relieve him of a sense of discomfort in the affected side by virtue of section of certain sympathetic filaments running in the phrenic. In a paper published by Dr. C. A. Perret, Dr. C. A. Piguet, and Dr. A. Giraud, in the *Presse Médicale* for April 11th, an account is given of the present position of artificial phrenic nerve paralysis in the treatment of pulmonary tuberculosis. Therapeutic experiments in this field have done much to throw light on the innervation of the diaphragm by the phrenic nerve. A few years ago the surgeons who performed simple division or resection of a short section of the phrenic in the neck were surprised to find how little the diaphragm was affected thereby. Subsequent investigations have shown that several nerve filaments may join the phrenic below the neck, and that if the phrenic is divided in the neck, and its distal end is pulled out slowly so that the filaments joining it lower down can be included in the resected portion, almost complete paralysis of the diaphragm ensues. This process, known as exairesis or evulsion of the phrenic, has been performed by the authors in two cases with considerable success, whereas they did little good in the three cases in which they performed simple phrenicotomy. In one of the cases in which exairesis was performed, and 15 cm. of the nerve was resected, the diaphragm was seen two days later to have ascended a hand-breadth and to be completely immobile. Yet there is no record of any great distress or pain, and, as Mr. H. Morriston Davies pointed out in THE LANCET of Feb. 28th, this freedom from pain and respiratory distress would seem to be the rule rather than the exception. Exairesis is evidently a valuable means, in carefully selected cases, of limiting the movements of the lung and thus giving it that rest which is so essential to the healing of tuberculous lesions. It is, of course, the basal lesion which is most suitable for this treatment, and it is well, as pointed out by the authors of the French paper to which we have already referred, that the disease should be of a fibrotic character with a natural tendency to healing.

THE HARVEY MEMORIAL AT HEMPSTEAD CHURCH.

FROM 1657 to 1883 the body of William Harvey lay in the vault of the Harvey Chapel in Hempstead Church, Essex, whence it was removed in 1883 and re-interred in a marble sarcophagus, provided by the Royal College of Physicians of London, within the church. It is now proposed to rebuild the tower of the church as a further memorial, at a probable cost of £5000, of which £450 have been contributed locally. The parish is small and chiefly agricultural, and it is hoped that laymen as well as the members of the medical profession will contribute. The old tower fell in 1882 and of the five bells the tenor was shattered; the other four escaped injury and are hung in the churchyard. The original tower was a four-sided edifice, somewhat severe in style, in four stories with a battlemented top and two windows with tracery. Times are hard and taxation is high, but medical men of all nations should feel it a duty to erect a tangible memorial of one of the great men of their profession, and we earnestly hope that the scheme may materialise. There is no need to emphasise at this date the importance of Harvey's discovery; suffice it to say that the whole of modern medicine depends upon it. And for those who are Churchmen the restoration of a church tower is an act of grace. Subscriptions may be sent to Dr. Sidney Phillips, Royal College of Physicians, Pall Mall East, to Mr. A. W. Ruggles-Brise, hon. treasurer, Spains Hall, Braintree, or to the Rev. T. P. Conyers Barker, Hempstead Vicarage, Saffron Walden, Essex.

PHTHISIS AND INDUSTRIALISM.

WE have already referred[1] to the first and second Harben lectures for 1924, delivered by Prof. E. L. Collis. The publication of these has been completed in the May issue of the *Journal of State Medicine*. The first two were devoted to determining whether, and, if so, in what way, the rise of industrialism in different countries has influenced the prevalence and age-incidence of phthisis. The lecturer claimed the influence to be profound and, from its study, looks upon the occurrence of the disease as a reflection of the existence of malnutrition in early adult life and wear-and-tear in later life. The third lecture deals with the question whether an alteration in age-incidence, such as has taken place for phthisis, might not be a manifestation exhibited when epidemics of infection wax and wane. The records of measles, enteric fever, whooping-cough, diphtheria, influenza, and particularly of scarlet fever are examined. Influenza provides evidence of an interesting occurrence: previous to 1918 the mortality from this disease had displayed a normal curve. Then suddenly, in 1918, the curve altered and came to possess a remarkable peak in early adult life coinciding with the peak for phthisis mortality which had been growing higher and higher at that period of life as food scarcity became more pronounced. The suggestion is made that the similar phenomena thus exhibited by the two causes of mortality occurring at the same time and under similar conditions had a common origin. Only in the case of scarlet fever is a definite move in age-incidence to later years of childhood found to have occurred in the past half-century, while the mortality both from this disease and from phthisis has been falling. When, however, the age-incidence of attack during the rise and fall of epidemics of this disease was closely examined (for this purpose five years admissions to the Glasgow Fever Hospital were employed), no evidence of any significant difference in age-incidence was found; in other words, no support was forthcoming for the view that the move over 50 years is epidemiological rather than social.

---

[1] THE LANCET, April 25th, p. 880.

The evidence produced in this lecture is at best only evidence by analogy; it has clearly been collected at the expenditure of much time and trouble. But whether, if sound, it really helps to assure us that the fall in phthisis mortality is not a mere dip in a long wave which must inevitably rise again is doubtful. Prof. Collis clearly holds an optimistic view and seeks for foundations for his faith. Possibly others with access to other records will examine them and publish their results, for the matter is one of practical significance in efforts to eradicate tuberculosis. In any case, the effort shown in these lectures to interpret vital statistics in the light of social conditions is to be welcomed.

THE ALLEVIATION OF DEAFNESS.

IT is acknowledged by all otologists that the results of the treatment of chronic otitis media, otosclerosis, and nerve deafness have hitherto been disappointing. Only a few weeks ago Dr. J. Kerr Love,[1] President of the Section of Otology of the Royal Society of Medicine, said:

> "Outside of surgical treatment there has not been great advance in otology. We can hardly do more than we could do fifty years ago for the cure of deafness. We are only beginning to try to prevent deafness, and the consequence is that the management of chronic deafness is largely in the hands of the empiricist and the quack."[1]

Any new method, therefore, which afforded a chance of the improvement of chronic deafness would be welcomed. Up to the present the treatment of deafness by so-called re-educative methods has not been received with general approval by otologists either in this country or abroad. There have been, it is true, a few enthusiastic protagonists of the method, such as Dr. J. Helsmoortel, of Antwerp, who published in 1913 a pamphlet on his successful results, and Dr. A. Raoult,[2] of Nancy, who reported in 1913 good results in 35 cases. At a meeting of the Scottish Otological Society in June, 1914, the late Dr. W. G. Porter [3] reported favourable results in a few cases, but the outbreak of war left unredeemed his promise to report further. The method of treatment has laboured and labours under several disadvantages. When it was first introduced into this country it was in the hands of medically unqualified persons. The instrument most commonly employed, the electrophonoide, was sold at what appeared to be an extravagant price; though we are willing to believe that when the intricacy of the mechanism is considered the price is not an extravagant one. It is impossible to give a prognosis regarding the possible success with any deaf patient until a preliminary course of treatment has been undergone. Even after a full course of treatment the improvement in the hearing is not usually permanent; in favourable cases it may continue for two or three years, but more commonly, even according to its most enthusiastic advocates, it does not last for more than six to nine months, when a further course is necessary. The method has, therefore, had to bear such adverse comments as that of Dr. Dan McKenzie, that "the impression exists that in the camp of re-education the smoke of the incense burned to the Golden Calf is just a little too plainly discernible." Dr. A. A. Gray [4] has dismissed the electrophonoide method as negligible because of the results in three of his patients who were treated by it; in two there was no improvement, and in the third the improvement was so slight as to be of no importance. In this country the most important study of the method previously published has been that of Mr. F. F. Muecke,[5] who reported in 1914 that his experience with re-education had not been satisfactory. He treated 36 cases; one was cured (a case of neurasthenic deafness); in three there was definite improvement; ten improved but relapsed later; and 22 remained in statu quo.

The article by Mr. George C. Cathcart in this issue of THE LANCET has, therefore, some importance as being the first categorical summing-up in favour of this method of treating chronic deafness to be published in this country. The instrument he has employed is the "electrophonoide" of Mr. Zund-Burguet, who, we believe, is a teacher of the deaf in Paris. The principle of this instrument is explained in the article, and the treatment apparently consists in vibration of the tympanic membrane, vasodilatation of the vessels of the tympanic membrane and the middle ear, and stimulation of the nerve-endings in the internal ear, by vibrating ear-pieces which convey sounds corresponding to the registers of the human voice. Mr. Cathcart makes the very definite statement that of his 100 cases of chronic progressive deafness, selected only in the sense that each had been examined and dismissed as incurable by two or more fellow otologists, 68 per cent. have improved after treatment with the electrophonoide. Making every allowance for possible error, this is not a statement that can be gainsaid wholly by such a suggestion as that "the improvement in the mental condition is produced by such an imposing apparatus."[6] In face of Mr. Cathcart's figures and his restrained presentation of the case in favour of the method, the treatment of chronic deafness by mechanical "re-education" does indeed appear to deserve some serious consideration by otologists.

THE ENDOCRINE FACTOR IN CHRONIC ARTHRITIS.

EXPONENTS of the septic-focus theory of the ætiology of chronic arthritis can point to a long series of cases which have been markedly benefited, if not completely cured, by the removal of some hidden source of toxicity. Opponents of this theory can indicate an equally large army of sufferers who continue in the same condition despite ruthless extirpation of teeth, tonsils, appendix, and every other potential lurking place of bacteria. A possible reason for this discrepancy is put forward by Dr. A. K. Thompson in the *Boston Medical and Surgical Journal* of April 2nd. He points out that focal infection may lead directly to an arthritis, but that it may also produce an endocrine disturbance which causes joint affections in its turn. If this interference with the endocrine system has been induced, the removal of the primary focus will have no effect on the arthritic condition, which is maintained by the failure of the internal secretions. Various observers have noted the association between arthritis or rheumatism and modifications of the thyroid function, either of defect or of an incomplete Basedow's syndrome. Lancereaux and Paulesco have recorded remarkable success through the administration of thyroid in chronic rheumatism. Dr. Thompson divides arthritis into three groups. In the "isotrophic group" he includes all cases which are not manifestly atrophic or hypertrophic; for these the method of treatment by removal of foci, immunisation, shock-therapy or medication, is firmly established. The atrophic group corresponds closely to "rheumatoid arthritis" and is the form most commonly encountered. A derangement in calcium metabolism is probably a potent factor. The vasomotor phenomena of this group have been associated by MacAlister with perversion of the thyroid, and there is, according to Dr. Thompson, distinct evidence of endocrine dysfunction, either hyper- or dys-thyroidism, or the presence of endocrine foci of sepsis. The hypertrophic group corresponds with what is usually known in this country as "osteoarthritis," and signs of hypothyroidism have been noted in almost all cases. Metabolism is subnormal and there appears to be a hypertrophic diathesis with inability to disperse lime salts properly. The administration of thyroid extract is of particular value in this type of case. There are probably few chronic disturbances of the body which do not in some measure affect the endocrine system, but the therapeutic possibilities of Dr. Thompson's conception are of great interest to the practitioner. Any way of relieving, if not of curing, the painful and disabling joint conditions which are constantly being presented to him is worth serious attention and experiment.

HUXLEY.

Thomas Henry Huxley was born at Ealing on May 4th, 1825, and when he died at Eastbourne on June 29th, 1895, he had been for 20 or 30 years about the best known scientific man in England. With his many fundamental discoveries in zoology and with his many distinctions in other fields, the fact that he was a qualified medical man had little to do. The profession may, however, pride itself on the memory that almost the only regular teaching he ever received was as a medical student at Charing Cross Hospital—a memory revived annually in the Huxley Memorial Lecture—and that it was an appointment as a ship's surgeon in the navy which gave him his practical start in life and the chance of exploring the wonders of the ocean, which he did to such good effect that he was elected a Fellow of the Royal Society at the age of 25 and received a Royal Medal in the following year; in 1881 he became President.

Huxley was in the first place a distinguished comparative anatomist with a bent for philosophical generalisation, and at the same time a horror of letting his imagination run in front of the facts of structure which were before him. For 25 years he worked in that doubting period of biological thought when, among Lyell and Scrope's uniformitarianism, Cuvier's archetypes, Oken's idealism, and the accurate examination of structure by Johannes Muller and his companions, the world was groping its way to the realisation of the broad truth which Darwin drove home in the "Origin of Species." And in the cumulative development of knowledge which led up to the revolution of 1859 Huxley played a prominent part with such contributions as his recognition and delimitation of the Hydrozoa as a natural group and his work on the theory of the vertebrate skull. Once Darwin had provided a mechanical conception of how evolution worked, Huxley was persuaded where the philosophy of Lamarck and Herbert Spencer had failed to convince him. He became one of the most active protagonists of the new doctrine, and his own work, now largely palæontological, centred round it. In the second place Huxley was for 31 years an inspiring professor of natural history at the Royal School of Mines, and when he got facilities at South Kensington in the early seventies he introduced the method of practical class-teaching with types of animals and plants which has been everywhere imitated with such success. As a memorial it would have been appropriate if the "Huxley and Martin" of those early days had not been replaced so largely by the almost equivalent "Marshall and Hurst." And, in the third place, Huxley was a good citizen who felt it laid upon him to rebuke error and propagate truth, and the last third of his life was mostly occupied with his public duties. It is in some ways a little unfortunate that the general public knows him best by his controversial activities. He had a hatred of dogma and privilege and pretence which seems now rather over-fierce, and it is hard for us to be enthusiastic over his polemics with Mr. Gladstone and the Duke of Argyll about the literal truth of Genesis. He hit harder than is customary nowadays, and when he said that you could always remember which side of the heart the mitral valve was on by reminding yourself that bishops were never in the right, he had perhaps forgotten that his first paper to the Royal Society was communicated by the Bishop of Norwich. But our very difficulty in fully sympathising with his position simply means that he and his fellow workers in the cause of freedom of thought succeeded, and it is in large part their work which has led to the broad-minded toleration which makes such controversies impossible in this country—though not in America—at the present day. There was a time when Huxley's name could hardly be mentioned in genteel society; he was a declared agnostic and perhaps he declared it rather loudly. But in calmer days it is not difficult to see peeping out of his writings a rather wistful longing that the intellectual discipline which he had imposed on himself would let him believe a few things which he could not prove. "To do justly and to love mercy and to walk humbly with thy God" was his epitome of an ideal religion.

ONE HUNDRED OUTBREAKS OF FOOD POISONING.

FOOD interests everyone, whether admittedly or not, and food poisoning has a very particular interest. Early in 1921 the Ministry of Health invited the coöperation of the Medical Research Council in investigating outbreaks of food poisoning on lines arranged by the Ministry in consultation with Dr. W. G. Savage, medical officer of health for Somerset. The special report[1] before us gives a plain record of 100 consecutive outbreaks, taken without selection, the large majority of which occurred in the years 1921–23. The problems involved are numerous and complicated, and in spite of the special laboratory facilities provided at Weston-super-Mare and the collaboration of Mr. P. Bruce White working whole-time in the bacteriological laboratories at the University of Bristol, the main features of the subject have not essentially changed since Dr. Savage's report to the Local Government Board in 1913. The present report is practically confined to serious and extensive outbreaks of food poisoning, but only for the reason that records of slight outbreaks are scarcely ever published and are but rarely brought before the public health authority at the right time. On the one hand, the special laboratory itself suffers from the inadequate material sent to it. On the other, all the reported outbreaks of food poisoning are not necessarily such, even when so described in the verdict of a coroner's court. A miner, for instance, who died in the Bishop Auckland Infirmary with symptoms regarded as typical of botulism, was stated in the verdict to have died of poisoning probably caused by tinned tomatoes. Later inquiry elicited the fact that on the day previous to eating the tomatoes he had suffered from stiffness of the neck, which gradually developed into the classical picture of tetanus. Nevertheless, the case was widely circulated in the press as one of botulism. Four children taken ill in a Manchester family, three of whom died, were supposed to have been poisoned by tinned treacle. Evidence, however, pointed to death from some infection, the nature of which could not be fully determined. Idiosyncrasy plays but little part in food poisoning. Contrary to the common supposition that one man's meat may be another man's poison, Dr. Savage and Mr. White state quite definitely that in all the outbreaks they investigated the infectivity rate was high and in general all who ate the incriminated food were made ill.

---

[1] Medical Research Council. Special Report Series No. 92. Food Poisoning: A Study of 100 Recent Outbreaks. By William G. Savage, M.D., B.Sc., and P. Bruce White, B.Sc. H.M. Stationery Office. 1925. Pp. 112. Price 2s. 6d.

Of the 100 outbreaks here recorded 66 were due to members of the Gaertner group of bacilli, which the authors now prefer to call the Salmonella group. Four others were due to the dysentery group, 8 were outbreaks of cheese poisoning, 7 of undetected bacterial origin. In no case was any strain of the colon bacillus found responsible for an outbreak. The Salmonella group, therefore, takes the lion's share in the attacks. Concerning the vehicle of infection, canned meat and canned fish accounted for 29 cases in which Salmonella toxins were the cause of poisoning, made-up meat for 10 and other forms of meat for 6 of the 28 cases in which the living bacillus was responsible. Bacilli, the report states, may remain alive but dormant in canned foods for indefinite periods. Great uniformity was recorded in the symptoms of bacterial food poisoning; diarrhœa, vomiting, and abdominal pain being very constant, eye symptoms quite rare. In outbreaks due to undestroyed toxin the attack follows rapidly, two to four hours, after ingestion and the acute effects may pass off within 24 hours or less. Case-mortality is low apart from the 100 per cent. mortality of the one recorded attack of true botulism at Loch Maree in August, 1922. The mortality from living Salmonella strain is put down at 1·2 to 1·3 per cent., although such attacks must always be considered potentially dangerous to life. Death from Salmonella toxin is much more uncommon. There was no death from the eight cheese outbreaks. Milk, although so favourable a medium for the growth of Salmonella bacilli, shows a singularly low case-mortality, less than 0·2 per cent., in fact. As to the path of infection, in outbreak after outbreak the authors could not get beyond the certainty of infection with Salmonella strain. They assert that there is no evidence that such bacilli are natural inhabitants of human or any animal intestines. Habitat outside the animal body, though possible, is mere hypothesis; and extremely few outbreaks of food poisoning in the literature can be ascribed with confidence to infection from a human source. All the available facts suggest contamination of food, originally bacterially sound, with bacilli derived from outside the food. Evidence was obtained of infection of brawn from the mould in which it was made, of meat pies from tank water, of cockles from contaminated sea water; but the authors frankly confess themselves as signally unsuccessful in obtaining proof exactly how and where the specific infecting bacilli originated. Rat or mouse is a possible source; the fly theory is unlikely inasmuch as flies are ubiquitous and multiple outbreaks of food poisoning never have occurred. Of 16 outbreaks of canned meat, of which the place of origin was obtainable, in all but one the meat was packed in South America.

The report concludes with an important section on the means for prevention; first and foremost diffusion of more accurate knowledge of the true nature of food poisoning, leading to careful epidemiological and bacteriological investigation. The authors have been profoundly impressed with the unsatisfactory way in which many cases and many small outbreaks involving a death have been investigated. It should be legally recognised, they think, that made-up meat-foods require special supervision and control; such foods, that is, as brawn, potted meat, meat pies, and sausages, every person carrying on such a business should do so under licence in premises where bacterial contamination is unlikely or impossible. An appendix to the report contains details of all the 100 cases, many of which are reported here for the first time. The report will be a revelation to many how frequent and serious are these outbreaks. The reader will hardly fail to gain the impression that they are avoidable.

THE COLLEGE OF PHYSICIANS IN PHILADELPHIA AND ITS MEDICAL MEMENTOES.

We have received from Dr. W. W. Keen, the present custodian of a cabinet of medical mementoes now in the possession of the College of Physicians in Philadelphia, a pamphlet descriptive of the articles contained therein. The custodianship was founded by Robert Abbe, of New York City, an Associate Fellow of the College. Personal relics of great men, something which they have touched or worked with or worn or used, seem to bring us who live after them (though one of the articles in the cabinet was presented by a living donor, Madame Curie) nearer to the former owners than a picture or statue. The relics in question are the shoe buckles and watch of Benjamin Rush (1745–1813); an inkstand and a lock of the hair of Edward Jenner (1749–1823); a case of instruments used by Joseph (Lord) Lister (1827–1912), and some test-tubes of sterilised milk used by him in his earliest researches on fermentation, which, though exposed to the air, kept sweet for many years and are still unputrefied, though some are mouldy; a model of a crystal of tartaric acid made by Louis Pasteur (1822–1895); and finally a piezoelectrometer used by Madame Curie and her husband in their researches on radio-activity and presented by her. St. George's Hospital preserves with pride the hide of the cow from which Jenner took his first vaccine, and the Philadelphia College of Physicians may rightly boast of its possession of relics of scientific research of equal value. Dr. Keen, in a letter which we have received from him, asks for information about any articles of a similar kind belonging to William Harvey, André Vesalius, or Ambroise Paré, if such there be, as he is anxious, if possible, to add them to the contents of the cabinet.

DR. SAMUEL JOHNSON AND MEDICINE.

Of men of letters who have paid tribute to medicine not the least was Dr. Samuel Johnson, who numbered some of the most influential physicians of the eighteenth century, as well as some less distinguished, among his friends. An interesting account of Dr. Johnson's connexion with medicine and with those who practised it was given by Dr. Robert Hutchison at the social evening of the Royal Society of Medicine on May 4th, where he showed on the epidiascope a series of portraits of the lexicographer's medical friends. Although a victim of almost constant bad health, Dr. Johnson declared that illness was of little expense to him, thanks to the generosity of his physicians, a thought which he developed later into the statement that no estate had ever been raised by medicine. But Dr. Richard Warren, Lettsom, and Fothergill earned huge incomes—proportionately more than any physician earns to-day—therefore it must be supposed that not all distinguished patients paid their fees on Dr. Johnson's scale, who rewarded the services of Warren with a copy of "The Lives of the Poets." Johnson was fond of the society of doctors, and of the nine members of a little club he formed in 1749, three were medical men, one Dr. Richard Bathurst, "dear, dear Bathurst," "a good hater," and a "man after his own heart." Unfortunately, all three physicians came to a sorry end, but many of Johnson's later friends were most distinguished. Chief of them was Dr. Thomas Lawrence, a man of "strict piety and profound learning," William Heberden, "ultimus Romanorum, the last of the learned physicians," and Brocklesby, "a liberal friend." Johnson was, of course, acquainted with the illustrious Lettsom, who formed a very just opinion of Johnson's character—"not polite, but not rude, with a glance like lightning out of a dark cloud"; a more generous description than was given by Dr. William Cuming (one of the founders of the Royal Medical Society of Edinburgh), who described Johnson as "sententious, oratorical, and dogmatic, possessed of a feline malevolence—a most unamiable being."

That Dr. Johnson's own medical knowledge was not inconsiderable is not surprising in a man of such inexhaustible concern in all human affairs. Much of his medical lore was gained from Dr. James, the originator of James fever powder and the author of a medical dictionary, in the compilation of which Johnson assisted. And doubtless he picked up a good deal from his servant and companion, Robert Levett, who had been a waiter in a French coffee-house until some friends subscribed money to enable him to attend medical lectures at St. Bartholomew's Hospital. Levett was practising among the poor when Johnson met him in 1746, and his fees were often paid solely in bacon and gin. Johnson's medical views were surprisingly modern; he was a teetotaller in a hard drinking age and condemned polypharmacy in all its forms, although he was fond of prescribing for himself and for his friends—also perhaps a modern trait. On medical ethics he expressed opinions which he was well qualified to give, and fulminated against snap-shot diagnoses. Though he held that a patient should be told the truth on all occasions, he did not always like to hear it himself, but in his last illness he insisted that nothing be hid from him. He must have been a trying patient to nurse, yet he never feared the surgeon's knife; when Cruikshank the surgeon scarified his legs for dropsy, Johnson, considering the cuts were not deep enough, dug a pair of scissors into his calves, saying to Percivall Pott, "You would not have me, for fear of pain, perish in putrescence." Dr. Johnson had himself, the lecturer said, the necessary qualities of the physician; the lame, the halt, and the blind found a refuge in his house, although it must be admitted he had hardly the bedside manner. At the close of the lecture, the President, Sir StClair Thomson, asked Mr. Augustine Birrell, who was present, to propose a vote of thanks to the lecturer. Mr. Birrell, in a vivid speech, inspired by his love and admiration for the subject of the paper, said that having seen the portraits of these eighteenth-century physicians, he wondered that Johnson's life had not ended prematurely. The amazing thing about Johnson was the interest he aroused in all men—people talked about him during his life, were talking about him still, and would go on talking about him.

THE fund inaugurated a year ago to perpetuate the public services of the late Sir Malcolm Morris has now been closed and the money allocated in providing a bi-annual prize at St. Mary's Hospital, Paddington, to the final year's student best qualified in dermatology, and in endowing an annual public lectureship under the Chadwick Trust upon the preventive aspects of public health and upon dermatology in alternate years.

HUNTERIAN SOCIETY.—A Dinner Meeting of this Society will be held at Simpson's Restaurant, Cheapside, on Monday, May 11th, at 7.30 P.M. After dinner, at about 8.30 P.M., the annual general meeting will be held. When the business of the annual general meeting is concluded Mr. Morley Roberts will read a paper on the Life of Dr. Henry Gawen Sutton.

AN AMERICAN HEALTH CONGRESS.—In order to give health workers from every part of the United States of America a general view of the public health movement in its broadest aspects, the National Health Council at 370, Seventh-avenue, New York City, has organised an American Health Congress to be held at Atlantic City during the week ending May 22nd, 1926. Leading authorities on each phase of the public health movement, such as tuberculosis, cancer, heart disease, blindness, social and mental hygiene, public health nursing, preventable diseases, and positive health education for both children and adults, will present the latest and most authoritative findings and programme for the solution of these problems. In addition to the various associations under the National Health Council it is anticipated that leading health associations of Canada, Mexico, and elsewhere will coöperate in this congress.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CXXI.—THE TREATMENT OF EXCESSIVE LOSS AT THE PERIODS.*

II. WHEN THE UTERUS IS FIBROID, NORMAL IN SIZE, OR UNDERSIZED.

Fibroids.—Fibroids cause excessive loss at the periods, partly by increasing the size of the menstrual area, partly by augmenting the vascularity of the uterus, and partly by interfering with the retractility of its muscular wall. The amount lost bears no constant relation to the size of the tumours. One feature of fibroids is, however, pretty constant—namely, that they prolong menstrual life until well over 50 years. This is an important point to be considered when advising treatment. Menorrhagia due to fibroids should in nearly all cases be treated by removal of the tumour either by (1) myomectomy, or (2) hysterectomy, partial or total. Preservation of the uterus is desirable on several grounds, of which we may place first the potentiality for conception in a patient of child-bearing age. Beyond this, however, the idea of losing the womb is repugnant to most women, even though conception is no longer possible. Moreover, the removal of the uterus seems to hasten by a year or two the natural age-atrophy of the ovaries, so that the climacteric is hastened. A further point is that hysterectomy may have a psychological effect on the sexual attitude of both wife and husband, because desire is chekced by the fact that the sexual act has lost its main significance.

Myomectomy, then, is the operation of election, but conservation is only advisable under certain conditions. An important one is that the surgeon should see the patient before her health has been seriously injured by hæmorrhage; where a woman has been bled white, even the amount of blood lost at a normal period is too much for her, and the quickest way to restore her to health is to stop the periods altogether by hysterectomy. Moreover, when the tumours are many and large the operation becomes a more difficult one than hysterectomy. For these reasons surgery should not be delayed, since there is a period in the life-history of all fibroids, be they ever so large, so numerous, or so harmful in their effects when they could be safely removed without sacrificing the uterus. Generally speaking, myomectomy is the proper operation for patients under 40 years of age, and hysterectomy for those approaching 50, while for those of intermediate age the decision depends on individual circumstances. I believe that most fibroids begin to be formed in the later twenties or early thirties, much earlier than is generally thought. I base this view on the fact that though I have now performed myomectomy on many relatively young patients, only twice have I seen new fibroids form, and those very small ones. No rule as regards the size and number of the tumours can be laid down. Large tumours are often easier to remove than small ones. Much depends on their situation in the uterine wall. I have removed as many as 52 fibroids from one uterus, reconstructing the organ afterwards, so that six months later it felt on examination to be absolutely normal. Finally, I would again emphasise the importance of surgical interference as early as possible. When hysterectomy is necessary I believe the subtotal operation to be preferable whenever the cervix is reasonably healthy.

Radium has been advocated in the treatment of certain cases of small fibroids, but I strongly disapprove it. It is a blind proceeding and not unassociated with risk. Anyone who is familiar with the conditions found in a myomatous uterus after removing it knows how different they frequently are from what they were imagined to be before the operation; thus an enlargement held to be due to an interstitial tumour may be found to result from a pedunculated mass, accurately filling the cavity. Radium checks uterine hæmorrhage by destroying the endometrium, but it often destroys some of the musculature as well, and thus a fibroid may be caused to undergo necrosis, a dangerous thing. Moreover, small fibroids are those most suitable for myomectomy.

---

* The first section of this article appeared in THE LANCET last week.

X Rays.—The treatment of fibroids by X rays I heartily condemn. It is in effect a revival of the bad old operation of double oöphorectomy for fibroids; ablation of both ovaries led to an acute climacteric, and in a proportion of the cases the periods ceased and the tumour ceased to grow, or partially shrank. The price paid for this relief was an acute "change of life" with all the miseries which accompany it; worse than this in quite a number of cases neither the bleeding nor the growth of the tumour was checked. X rays effect a bloodless oöphorectomy followed by results exactly the same and exactly as variable as the old operation. I have now a number of times had to operate on patients after they had had both ovaries unavailingly destroyed by X rays. Moreover, I have seen irradiation followed by acute septic degeneration of the tumour and by severe X ray burning of the abdominal wall. It is, to my mind, a bad and retrograde procedure which appeals to the fearful patient as a means of escape from "the knife," though the physiological and anatomical alterations produced by it are in reality far more serious than those produced by hysterectomy, whilst the ideal surgical procedure of myomectomy cures without disturbing either function or normal structure.

Menorrhagia with a Normal-sized Uterus.

Patients with a uterus of normal size are more difficult to treat because the cause of the bleeding is more obscure. The conditions which cause an unenlarged uterus to bleed too freely are mainly two—uterine fibrosis and so-called endometritis.

Uterine Fibrosis.—Uterine fibrosis, which is not dependent on subinvolution, is a true inflammatory fibrosis and is typically seen in cases with a history of definite uterine infection. It may follow gonorrhœal, puerperal, and post-abortional infections. The uterus is not enlarged, but it is very hard and fibrous, whilst the endometrium is much reduced in thickness. The menorrhagia is often exceedingly severe, and to complicate matters a large proportion of the patients are quite young women who desire children and have none. Some have previously been operated on for inflammatory disease of the appendages. Curettage is quite useless, though many of these women have been curetted several times and have taken every known uterine styptic.

In such circumstances two courses remain: (*a*) to remove the uterus or (*b*) to use radium. I would, in most instances, remove the uterus, firstly, because it is a useless organ, and secondly, because in many cases it is still the seat of chronic infection. Radium has a better field here than when the uterus is enlarged and much success has been claimed for it. My own experience is that though it checks the bleeding or even stops it altogether for several months, not infrequently the menorrhagia presently recurs and a further dose is requisite. Repetition of the treatment is not without risk. I have seen several cases in which deep necrosis of the uterine wall was produced. My impression is that the first application of the radium produces a condition of low vitality in the tissues affected on which a second application may act with destructive effect. A further objection to radium is that its prolonged or repeated use causes atrophy of the ovaries in the same way that X rays do. This is a very disastrous thing if the patient is young.

So-called "Endometritis."—Cases in which no obvious change in the uterus or uterine wall can be discovered, and yet the woman bleeds too freely at her periods, are most difficult to treat, for we know little of the process of normal menstruation. Many of these cases are labelled as "endometritis," but there is no histological evidence of this condition. It seems reasonable to suppose that there may exist some abnormality of the function of the ovaries or of the glands correlated to them, and on this theory endocrine treatment has been extensively employed of recent years. The results obtained are very unequal, nor do they help us to formulate any scheme of administration. The various ovarian extracts now on the market, together with thyroid, pituitary, and mammary substances, should be tried, but as to which combination is likely to give the best results in any individual case we have no certain knowledge. These, together with the uterine styptics, constitute our first line of attack. It is noteworthy that some of these cases of menorrhagia get well of themselves after all treatment has failed.

Curettage achieves success sufficiently often to be well worth a trial. This failing, *radium* may be tried. Its effect is identical with that of curetting in so far as it produces superficial destruction of the endometrium, but it produces far more fibrosis than does the curette and hence its effect is more likely to be lasting. On the other hand, the dangers and drawbacks referred to above accompany its use.

In place of radium, or following the failure of radium, we have *abdominal hysterotomy* with curettage from above. The operation has the advantage of enabling the surgeon to obtain accurate knowledge of the condition of the uterus and occasionally reveals a definite though unsuspected cause for the bleeding like a small polyp, or a localised thickening of the uterine wall, which can be excised. Finally, we come to those distressing cases where, other treatment having failed and the patient being very anæmic, it is necessary to remove the body of an apparently normal uterus. X ray treatment should never be employed for reasons already given.

Menorrhagia with a Uterus Smaller than Normal.

A small uterus does not necessarily mean a small monthly loss; the most profuse and persistent menorrhagia may proceed from the undeveloped organ, possibly because the defective musculature is unable to close down upon and control the vessels of the uterine wall. Patients with this type of uterus are young and usually unmarried, and are therefore most undesirable subjects for any drastic steps. Endocrine treatment may first be tried in the hope of stimulating further development of the uterus, combined with ergot, styptol, hydrastine, and so forth. This form of menorrhagia may improve after marriage, whilst pregnancy is most desirable since it may result in cure; conception in an undeveloped uterus, though unlikely, is by no means impossible. Curettage should be tried, and radium may be employed seeing that if these measures fail it may be necessary to remove the body of the uterus. This step should not be delayed until the patient has passed into a profound anæmia, for then the risk of operation becomes very great. These cases of "terminal anæmia"—the end-result of severe and prolonged menorrhagia—are not so uncommon. The skin is dead white with a slight lemon tinge; the temperature may be 102° or 103° F.; the pulse is very rapid, up to 160, and "water-hammer" in type; the mind is alert and anxious, but not frightened; and from the vagina flows a steady stream of thin brownish-looking blood, usually with a very unpleasant odour. This state is invariably due to ill-advised persistence in palliative measures long after there has ceased to be any hope in them. Patients so ill will not stand a long operation; the surgeon must remove the uterus in 15 minutes or less in order to save more than a small proportion of them.

THE PROBLEM OF PROSTATECTOMY.

BY CHARLES A. PANNETT, M.D. LOND., F.R.C.S. ENG.,
PROFESSOR OF SURGERY IN THE UNIVERSITY OF LONDON;
SURGEON TO ST. MARY'S HOSPITAL.

THE enlargement which causes prostatic symptoms is most commonly benign in nature. It grows in a gland whose function is on the wane. It can be separated easily from its surroundings. It occupies a surgically accessible position. To begin with, the therapeutic outlook is good, but later, when the inevitable implication of the kidneys has occurred, the situation becomes serious and ultimately life-menacing. There may be no apparent signs of this grave change. The increasing inexorable demands upon the large reserve function of the kidney for ordinary physiological needs bring the patient imperceptibly to the point where he is unable to meet the smallest additional call upon his vitality. Any slight disturbance may precipitate a catastrophe; an operation will certainly do so. The root of all this trouble is the injury which the kidney cells suffer from having to secrete against unusually high pressure. After a certain stage the kidneys of a prostatic always show the changes of chronic interstitial nephritis and the alterations of form due to distension of the calices and pelvis. With this distension goes a distortion of the renal tissue, so that the collecting tubules may take a curved course to their mouths on the pyramids. This sinuous path, because the deformity has taken place gradually, is not accompanied by obstruction, but should the pressure in the kidney pelvis be suddenly lowered by catheterisation of an over-distended bladder, or by suprapubic cystostomy, the elastic recoil of the strained kidney tissue is liable to bring about an obstructive kinking of the collecting tubules, a suppression of urine to which the patient succumbs. At the critical stage of the disease it is dangerous to empty a distended bladder by any route unless it be done gradually. Symptoms of uræmia following rapid evacuation of the bladder have been banished by filling up the bladder again with fluid.

The retention of excretory products the result of the depression of the functional capacity of the kidneys would seem to exert a poisonous effect upon most other body tissues with disturbance of their activities. Cardiac degeneration diminishes the heart's power of response, so that failure may occur. Immunity reactions are enfeebled. There is a greater liability to succumb to infections. The hæmopoietic organs are insufficient, so that an anæmia appears. The removal by leucocytes of the shreddy necrotic walls of the cavity left after prostatectomy, the increased katabolism accompanying a mild febrile reaction, may bring the amino-body content of the blood to a point where the kidneys are inadequate to excrete the urea formed in the liver; or the crippled activity of these organs may be further interfered with by a diminution of the volume of circulating blood from an unavoidable hæmorrhage. In both cases uræmia supervenes. In connexion with prostatic disease the doctor, therefore, has a four-fold aim: (1) To intervene before the obstruction has reached a stage when the kidneys will suffer damage; (2) to recognise how far the patient's health has been undermined by his urinary disturbance; (3) to bring about that temporary degree of recovery which will allow of effective treatment to be carried out with a reasonable amount of safety; (4) to remove the obstruction in such fashion that the immediate risk will be the least possible with ultimate restoration of normal urination.

Decision as to the Necessity for Operative Measures.

Putting aside urinary infection, to which these patients are particularly prone, the first consideration must be the degree of urinary obstruction which exists and whether it has reached such a point that damage to the kidneys is already taking place. The index of this is the volume of residual urine. The existence of urine in the bladder after the act of micturition means that the wall of this reservoir has become permanently stretched, so that, by muscular contraction, it is no longer able to obliterate its cavity completely. That urine can be drawn off by catheter after the failure of natural efforts to expel it is due to the fact that the point of the inserted instrument fixes the apex of the bladder so that the weakened walls are now able to contract closely round the shaft. The proof of this is the ability to withdraw more with a silver than with the less rigid rubber catheter. Now the urine, during micturition, is prevented from flowing backwards up the ureters by the sphincters at their lower ends and the oblique passage of these tubes through the bladder walls. When the bladder has been sufficiently distended, both these protective arrangements fail to act. The sphincters become useless. The ureters run perpendicularly through the bladder wall. They dilate and the kidneys soon have to secrete against unaccustomed pressure. The valve mechanism at the lower end of the ureters becomes incompetent when the residual urine amounts to from three to four ounces. Hence the rule that measures for the relief of prostatic symptoms should be undertaken when the residual urine reaches this amount. The volume of residual urine and the presence and degree of infection determine whether or not prostatectomy should be contemplated. There is no difference of opinion to-day. The advantages of prostatectomy over catheter life have been amply demonstrated; the greater expectation of life which it offers alone is sufficient recommendation. The one essential is that a true estimate of the general condition of the patient be arrived at, so that he shall not knowingly be subjected to a strain beyond his powers to resist.

Determination of the Ability of the Patient to Undergo Prostatectomy Successfully.

It may be said at once that such knowledge cannot be obtained from one test alone. Neither is it possible to say, when considering the result of a particular test, that above a certain value operation is safe, whilst below it disaster will follow. The reports of a number of tests must be brought into review. Those clinical features which are insusceptible of measurement as yet must be given their due weight. In short, the value of the general clinical impression must be acknowledged and indeed acted upon. Signs of imperfect elimination are thirst, a dry furred tongue, loss of appetite, sleeplessness, evidence of loss of weight, often a mental unfitness. The heart sounds may be feeble and breathlessness appear on slight provocation. The hæmoglobin content of the blood may be much diminished. If it be below 60 per cent. the risk of operation is great, for the amount of blood which will be lost during the operation cannot be foreseen, nor can it be always controlled easily. The blood pressure is often high. If it is above 170 or 180 mm. Hg, conditions are not favourable for operative intervention. The state of the kidneys can be judged in a number of ways. If they are much damaged the urine will be of low S.G., 1002–1004, and the patient will pass more than the usual quantity, sometimes three times as much. The quantity of urea in the blood is high. If the urea-nitrogen in the blood be about 20 mg. per 100 c.cm. operation is fairly safe, if it amounts to 25–30 mg. there is considerable risk, if it be over 30 mg. the prognosis is bad. Of the special renal function tests, the best is the urea-concentration test. Many surgeons pay much attention to the phenolsulphonephthalein test, some to the indigo-carmine excretion. Of them all it is difficult to be dogmatic in fixing the point which separates danger from comparative safety. Thus, generally speaking, in the first test the concentration of urea should reach 1·5 per cent. before prostatectomy can be considered, yet sometimes a patient can be carried through to safety with a concentration under test of only 1 per cent.; and whilst he should be deemed a bad surgical risk if he fails to excrete 30 per cent. of the injected dose of phenolsulphonephthalein in two hours, cases are recorded where the excretion of this dye has been far below this percentage, yet the individual has survived prostatectomy. The kidneys are to be regarded as seriously diseased should the excretion of indigo-carmine be delayed longer than 10 minutes after the intravenous injection of 5 c.cm. of a 0·4 per cent. solution.

Preparation of Patients Unfit for Immediate Prostatectomy.

It is a fortunate fact that the precarious condition due to urinary retention toxæmia can be relieved by draining the bladder under proper precautions. It is astonishing how this simple measure will in a few days alter the whole clinical outlook. Whether urinary function, blood pressure, or general well-being of the patient be taken as the criterion, a very pronounced improvement can be demonstrated; so much so that prostatectomy, which before would certainly have proved fatal, can now be performed with relative immunity. It can therefore be laid down that when the tests detailed above show that much sapping of the patient's vitality has gone on, or when an examination of the urine shows that there is a serious urinary infection, preliminary drainage should always be instituted. This may be done by an indwelling catheter or by making an opening above the pubes. In any case, as has been pointed out, relief of tension should be gradual if there is any considerable degree of retention. Suprapubic drainage is necessary when the infection is severe, when no instrument can be passed, when the patient's urethra is intolerant, or when drainage must be maintained for long. In other cases drainage by catheter has obvious advantages. It not only saves the patient an operation, but it renders subsequent operation more easy. Suprapubic cystostomy has not counter-balancing advantages. Drainage, however it is carried out, always has a pronounced effect upon the patient. For the first four to six days his kidney function will be found to be considerably depressed. He is less fit than before. That is why prostatectomy should never be performed without primary drainage unless the functional tests are extremely good. The kidneys should not be subjected to the insult of drainage combined with operation at one time. The period for which drainage should be maintained varies very much. After an interval, improvement of the patient's condition becomes evident to all tests. Usually this will take place in two weeks, occasionally months of drainage are necessary. Such remarkable recoveries take place in patients with extreme nitrogen retention, as proved by blood estimations when drainage is instituted, that to relieve a prostatic of his hypertrophied gland need hardly ever be regarded as a hopeless problem.

Choice of Radical Operative Technique.

Two points merit brief consideration—the route by which the prostate should be removed, and the method of anæsthesia. The suprapubic operation is performed almost exclusively in this country. It is simpler and gives a higher percentage of good results in less skilled hands. The perineal operation has certain advantages. Shock is less, hæmorrhage appears to be less and more under control. The danger of incontinence or recto-vesical fistula can be obviated by careful technique. Neither operation should be performed to the exclusion of the other. The suprapubic route is to be preferred when suprapubic drainage has been necessary, when the enlargement is of the ball-valve type, when cystoscopy has revealed the presence of a stone. In most other cases the perineal route can be followed, with less anxiety for the immediate future.

General anæsthesia by ether is satisfactory on the whole. Spinal anæsthesia makes enucleation easy, but would seem to add to the risk should much blood be lost owing to the drop in blood pressure caused by it. The perineal operation can be performed absolutely painlessly by trans-sacral combined with epidural anæsthesia. This is an excellent method when it can be carried out. Suprapubic operations have also been done under local anæsthesia, but the writer has no experience of this procedure. A reliable easy local anæsthetic method would certainly oust ether narcosis.

Results of Prostatectomy.

Statistics seem to prove that of those patients who survive the operation more than 80 per cent. are restored to normal health. Nevertheless, it must be recognised that the lower operative mortality of the few specialists does not reflect the mortality in the general surgeon's hands. During convalescence, lung complications, sepsis, hæmorrhage, uræmia, or embolism may lead to the death of the patient. The mortality is lowered immensely by the careful pre-operative treatment described above. Uræmia can be almost certainly prevented, the resistance to infection is raised, so that lung complications, sepsis, and secondary hæmorrhage are very less likely to occur. It cannot be too strongly emphasised that precipitancy in prostatic surgery is always out of place. Prostatectomy must follow preliminary preparation and investigation, or unrecognised risks will be taken. It is not an emergency operation.

A patient who has lost his prostate may still suffer from an infection of the kidney which will not clear up. Some patients continue to have a certain degree of frequency. Quite rarely stricture occurs, and occasionally weak control after even a careful perineal operation. This diminished power of control, however, disappears in a month or two when the operation has been properly performed. The majority of patients return to complete health and lead active lives.

BRITISH INSTITUTE OF RADIOLOGY.

The British Institute of Radiology, of which Sir Humphry Rolleston is President, was founded some eighteen months ago, very largely through the keenness and initiation of the late Sir Archibald Reid, to provide a central bureau to house, coördinate, and extend the work of existing radiological societies. The premises are situated at 32, Welbeck-street, London, and constitute a centre for professional and social intercourse among those interested in radiological work. The *British Journal of Radiology* is published monthly as the official organ of the Institute, and the formation of an adequate reference library is provided for. The nucleus thus formed, however, has absorbed such small capital as was available, and in November of last year an appeal was made to the medical profession, to radiologists, and to the public generally, for £6000 to wipe out bank debts and provide for further development. Subscriptions were asked for in one or more of the following ways: (*a*) By donation to the General Foundation Fund; (*b*) by donation earmarked for the Reid Memorial collection; (*c*) by becoming a member (£1 1*s*. entrance and £3 3*s*. annually) entitling to receipt of journal; (*d*) by becoming a life member (£50) entitling to receipt of journal; (*e*) by becoming an Associate (10*s*. 6*d*. entrance and £1 11*s*. 6*d*. annually).

List of Donations.

We publish herewith a list of the donations received up to April 10th. From a survey of this list it will be seen that radiologists have responded to the appeal very satisfactorily, but their professional colleagues—with a few notable exceptions—have made little response; whilst the non-medical public, beyond a number of the late Sir Archibald Reid's personal friends, has hardly yet been reached. This position can be advanced only by individual members striving to interest their personal colleagues, friends, and patients. The total received in 18 months (up to April 10th), as detailed below, is £1680, and in nine months 52 new members have been enrolled. This effort may surely be quoted as a worthy basis for a further appeal.

PROCEEDINGS OF THE ROYAL COMMISSION ON NATIONAL HEALTH INSURANCE.[*]

(Continued from p. 944.)

EVIDENCE OF THE BRITISH MEDICAL ASSOCIATION.

IN its essentials the printed statement of evidence which is being placed before the Royal Commission at their sittings on April 30th and May 7th is substantially as it appeared in the original statement which was summarised in our issue of Jan. 10th. The differences are rather matters of drafting and emphasis to give effect to views which have been expressed in connexion with the conferences held to receive the views of the delegates from the several districts. The following condensed statement will, we think, sufficiently remind our readers of the points on which evidence is being tendered. We shall, in due course, give a summary of the oral evidence being given in exposition of this statement by Dr. R. A. Bolam, Chairman of Council; Dr. H. B. Brackenbury, Chairman of the Representative Body; Dr. H. G. Dain, Chairman of the Insurance Acts Committee; and Dr. Alfred Cox, Medical Secretary of the British Medical Association.

Authority of the British Medical Association.

Part I. of the evidence sets out that the Association has over 28,000 members, of whom some 19,000 are in Great Britain; that the majority of the members are general practitioners, but that the Association contains a strong representation of every section of practice; that its constitution enables it to ascertain and coördinate the opinions of its members; that the steps which have been taken in circulating papers and calling local and central conferences have been such as to ensure that every section of the profession was consulted; and, finally, that it is especially representative of insurance practitioners, its Insurance Acts Committee having been formally and repeatedly recognised as their official mouthpiece in negotiations with the Government. This part of the evidence is new.

Some General Aspects of the Insurance Scheme.

Though it is recognised that a National Health Insurance scheme is not necessarily, or even probably, the best means of utilising limited resources for the promotion of national health, yet if such a scheme is in existence, regard must be had primarily and constantly to the maintenance of health and the prevention of disease and not merely to the alleviation or cure of morbid conditions when once they have arisen. The existing machinery and the medical officers of the public health service should be brought into close and organic connexion with the insurance scheme. The conference of representative doctors held in 1922 resolved "that the measure of success which has attended the experiment of providing medical benefit under the National Health Insurance Acts system has been sufficient to justify the profession in uniting to ensure the continuance and improvement of an insurance system."

---

[*] In previous articles the proceedings of the Commission were reported under the following headings: Introductory Note; The Scope of the Insurance Scheme (see THE LANCET, Jan. 31st, pp. 247–8); The Provision of Medical Benefit (Feb. 7th, pp. 301–3; Feb. 14th, pp. 355–6; Feb. 21st, pp. 403–5); Financial Provisions of the Act (Feb. 28th, pp. 454–7); Medical Certification and the Regional Medical Staff (March 7th, pp. 508–9); The Approved Societies and the Money Benefits (March 14th, pp. 564–5; March 21st, pp. 623–4); Evidence of the Hearts of Oak Society (March 28th, pp. 677–9); Evidence of the National Conference of Industrial Assurance Approved Societies and of the Manchester Unity Approved Society (April 4th, pp. 731–3); Evidence of Independent Order of Rechabites, of Rational Association Friendly Society, and of Miners' Societies (April 11th, pp. 784–6; April 18th, p. 839); Evidence of Mr. Alban Gordon (April 18th, pp. 839–40); Evidence of Joint Committee of Approved Societies, of Stock Exchange and Lloyds' Health Insurance Societies, and of Group of Catholic Approved Societies (April 25th, pp. 889–91): Evidence of the National Insurance Beneficent Society (May 2nd, pp. 943–4).

References to the paragraphs in the printed statements issued as appendices to the reports of the oral evidence are given thus: "App. X. 69," and references to the oral evidence thus—Q. 1369.

The medical attention of the working population has, it is contended, greatly improved in many ways which are set out in the evidence, and this condition has certainly been hastened by the National Health Insurance scheme. On the other hand, the growing volume of regulations and machinery has been regarded by insurance practitioners as oppressive or even menacing, and has by itself deterred many practitioners from taking part in the service at all. Five broad principles are set out as fundamental in any National Health Insurance scheme. They are reproduced at the beginning of each of the following sections of the evidence.

Persons to be Provided For.

General principle : The medical provision should be available for those persons, and only for those persons, who would be unable to obtain it without the help of the insurance scheme.

The present scheme includes without any income limit all manual workers, and non-manual workers with an income limit of £250 a year. Certain classes are excluded. The Association is of opinion that the excluded classes should extend to such persons as bank and insurance clerks, that any income limit should be applied universally, and that unless a lower limit than £250 is generally applied, the limit must be lowered in connexion with any scheme for the inclusion of dependants.

While agreeing that the dependants of poorly paid earners might properly be included in the insurance scheme, a considerable body of opinion within the profession fears that the difficulties may be so great as to make the suggestion of including even these persons impracticable. An extension to all the dependants (numbering probably 23 millions) of the present insured population is wholly unnecessary and would in practice be found almost impossible. The inclusion of any dependants would have to be accompanied by a home nursing service and a lightening of the doctors' duties in regard to records and reports and in other ways, and by an extension of welfare centres. As regards necessitous persons (presumably those at present coming within the Poor-law) the profession is prepared to undertake their treatment if called upon to do so.

Extent of the Provision to be Made.

General principle : The medical provision made for insured persons should be, as far as possible, complete.

The profession desires that the medical services publicly provided under the auspices of local authorities and the treatment (dental, ophthalmic, &c.) benefits provided out of the surpluses of Approved Societies should all be made an integral part of the insurance scheme or brought in proper relationship thereto, and that the provision should be extended so as to include complete consultant and specialist advice and treatment, full laboratory facilities for clinical purposes, residential, institutional treatment so far as is possible with the limited accommodation, dental advice and treatment, such ancillary help as can be given by nurses and masseurs, and an ambulance service. In general, the services should be available only on the general practitioner's recommendation, disputes as to the need for the extra service being settled by an official referee ; in the case of dental treatment, however, there might be direct application to the dentist.

The medical personnel of the consultant or specialist service should consist of those registered medical practitioners who satisfy certain criteria as to status similar to those contained in the present medical benefit regulations as to the title of a doctor to give specialist treatment. The decision whether any individual practitioner does, in fact, satisfy these criteria should be in the hands of a local professional committee. In some areas consultant or specialist clinics might be established which might even be the out-patient department of a hospital ; there should be proper facilities for exchange of records with the general practitioner and for personal consultation.

In connexion with a suggestion that maternity work should be brought into close and proper relationship with medical benefit, the evidence suggests that:—

> Provision for a woman within the insurance scheme should be for (*a*) antenatal medical examination (if requested by her) and supervision, (*b*) attendance by a registered midwife during normal labour and the puerperal period, (*c*) attendance by the practitioner of her choice during labour and the puerperal period when his attendance is requested by the midwife under defined conditions or when as the result of his antenatal examination he has declared his personal attention to be necessary.

As regards a clinical laboratory service, it is thought that, as a highly trained pathologist would be required whose work could not be confined to that for insured persons, the laboratories should be maintained under other auspices and a suitable contribution made out of National Health Insurance funds. In regard to appliances, it would be a great advantage if the present restrictions could be removed and all necessary appliances supplied ; in some cases this might be on loan.

Terms of Service.

General principle : The conditions under which the medical attention is given to the individual should approximate as nearly as possible to those of private practice.

The insured person's freedom to change his doctor at any time ought of itself to solve the majority of questions of supposed neglect or improper behaviour on the part of a doctor. In regard to formal complaints the Association is of opinion that an appeal to the Courts should be possible not only on the ground of improper procedure as at present, but also on the ground that the penalty inflicted was out of proportion to the offence, and that in a case of proposed removal from the service the practitioner should have the right of appeal to a duly constituted central professional committee.

It is represented that the action of the Ministry of Health in a number of recent cases has given rise in the minds of many practitioners to a feeling of injustice or even a suspicion of vindictiveness. If a complaint has been dealt with under one part of the recognised machinery it should not be reopened or penalties inflicted under some alternative machinery, and in any case the propriety or otherwise of any particular method or line of treatment ought not to be made the subject of investigation in connexion with the insurance service

As regards approved institutions, it is urged that their standard of treatment is below that of the panel service, and that it is difficult to argue that they supply any such need of the community as justifies their retention under the general scheme of administration of medical benefit. With regard to certification, the profession looks upon the issue of a false medical certificate as one of the gravest offences of which a practitioner can be guilty. It considers that, in the main, medical certification under the Insurance Acts is remarkably well done, though the witnesses are prepared to reply to any allegations which may be made with regard thereto. It is desirable that the phrase "incapable of work" used in the Act in the certificates should be altered ; certificates containing this phrase can be signed honestly only because the words are now understood to have a technical meaning, which, however, needs a pamphlet to set forth accurately.

Administration.

General principle : Medical representatives should be closely associated with the administration of the scheme, and as far as questions of purely professional conduct and treatment are concerned, judgment should be in the hands of purely professional bodies.

The central administration of all health services should be under the control of the Ministry of Health, and the local administration of all these services should be in the hands of a local authority established *ad hoc*, or acting through a statutory committee analogous to the existing statutory education committees of local authorities. Of existing authorities it is probable that county councils and county borough councils would be found the least unsuitable.

If there were such a unification of medical services as those suggested above, this would involve the disappearance of insurance committees and the transfer of the health functions of the Poor-law guardians. It is certain, however, that many of the members and officers of these bodies would be indispensable for the work of the unified authority. Each such authority would have a chief administrative medical officer, who would, no doubt, in most cases be the existing medical officer of health. In each area there would be also a statutory local medical committee.

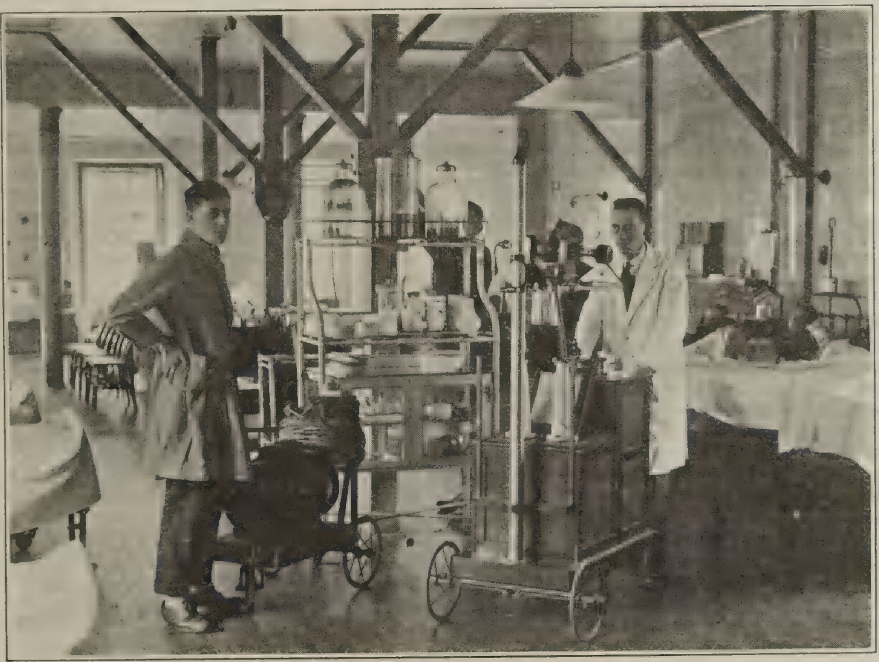
Remuneration.

General principle: Remuneration should be on such a basis as (1) would produce an income not less than that which corresponding responsibility and work should produce in comparable private practice, regard being had to all relevant considerations; and (2) would not prejudice the continuous supply of the best type of practitioner.

The actual amount of the capitation fee having been so recently settled, the profession has no wish to reopen the question at the moment. The fee does not, however, in their view, afford a proper remuneration, and the extra amount allowed for rural conditions requires reconsideration (an appendix to the evidence deals especially with the latter point). If consultant and specialist services are added to the insurance scheme, payment should be for each service or for each session according to a tariff, and the funds for the general practitioner service and the extra services should be kept separate and distinct.

THE REBUILDING OF MIDDLESEX HOSPITAL.

THE fabric of Middlesex Hospital, London, which has stood—and stood for so much—for the past 150 years now shows signs of imminent dissolution. Its floors are decayed with dry rot, the ceilings are cracking, and its shallow foundations are insecure. The serving of a "dangerous structure" notice has been averted only by the closing of two wards, the strutting of the basement and 14 wards with heavy baulks of timber, and the undertaking by the hospital authorities that the whole of the old building will be demolished as soon as temporary accommodation for the patients can be found. We reproduce a photograph of one of the strutted wards, where the wooden beams obviously cause as much inconvenience as they must, in a dusty city, be insanitary.



A "crippled" ward.

The board of governors have come to the decision that the only possible solution for the situation is the entire rebuilding of the hospital on its present site at a cost of £500,000. This decision does not depend on the state of the buildings alone, but in all departments expansion and modernisation are required in accommodation and equipment. The work of the cancer department, which will remain untouched under the reconstruction scheme, is indicative of what might be done in other branches of medical science if adequate facilities were available. Middlesex Hospital is to be rebuilt, not from choice but from necessity, and unless the huge sum of half a million pounds can be raised, the hospital must simply go out of existence. Serious attention is being given to this problem, and a meeting of the court of governors, under the chairmanship of Prince Arthur of Connaught, will be held on Monday, May 11th, when the whole question will be discussed.

There can in this instance be no suggestion of the sale of a valuable site and removal of the hospital, since the site is not the property of the hospital authorities, but is simply held at a nominal rent through the generosity of the Berners family. There are other cogent reasons for the rebuilding of the institution in its present situation—one of the most important being that the district which it serves contains a million and a half of working population. Another reason, of great weight, is that round the present doomed hospital buildings are grouped the modern and up-to-date cancer wing, the research departments, the magnificent Bland-Sutton Laboratories, and the well-equipped medical school. There can therefore, in our opinion, be no doubt that the hospital authorities have decided wisely in this matter. The present site is central, convenient of access both for patients and staff, and is in the midst of the working district it serves. It is also very near some of the busiest thoroughfares in the metropolis, where casualties cannot but be frequent.

There is room for the necessary buildings, and it should be possible to build a thoroughly up-to-date hospital worthy of the great reputation of the present institution, with adequate accommodation, now lamentably short, for the special departments. There should be general sympathy with the authorities in the gigantic task so dramatically imposed upon them. This will need the generous support of a very wide public, and we may hope that many of our readers will be able to help, both directly and indirectly. The work of an institution of this character is of truly national importance, for not only is it concerned with the large numbers of patients who seek treatment there, but both the governing body and the staff have shown real interest in the important matters of medical research and education.

They have made excellent use of the special opportunities afforded them. The hospital has taken a leading part in cancer research, and the excellent original work being carried out in pathology and in biochemistry, as well as in clinical subjects, is apparent from the reprint of articles published during 1924 that we have recently had occasion to review. Close coöperation between those in charge of the patients and the scientific specialists in the various laboratories has long been maintained and has contributed in no small degree to the success of the work of the hospital. It would be in the nature of a national loss, rather than a local calamity, if the hospital ceased to exist and if its varied activities were curtailed, or came to an end.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

The Development of Therapeutics.

Dr. D. Murray Lyon, professor of therapeutics at the University of Edinburgh, delivered his inaugural address in a class-room of the University on April 28th, Prof. Lorrain Smith presiding. In the course of an interesting account of the development of therapeutics, Prof. Murray Lyon said that one might recognise in the teachings of to-day many traces of long discarded theories. In the primitive phase of medicine the prevailing note was superstition, mixed with some sense as well as a certain amount of mysticism. Religion and medicine were closely allied at this stage and were administered by the same authority. Three views as to the causation of disease were common among primitive peoples: the religious view, that disease was due to some spiritual or non-human agency; the magical, that disease was due to human agency; or the natural, that disease was due to some simple natural cause. Traces of each type of belief, he said, might still be found at the present day. As for magic, who had not heard of the hard-headed business man who wore an "electric ring" or carried a potato in his pocket to protect him against rheumatism? The speaker then outlined the history of medical treatment from the brilliant period of the Greek philosophers to the present day of modern specific drugs and methods. While many of our drugs, he said, gave us almost absolute control over certain serious diseases, nevertheless a certain number of maladies were beyond the assistance of the medical profession. The victims of these for a time passed from one practitioner to another in search of cure, and eventually fell into the hands of quacks and patent-medicine vendors. Despite frequent statements to the contrary, medical men, well-knowing the shortcomings of their art, were willing to accept help from any quarter. Manufacturing chemists knew the weakness of medical men for trying out new forms of treatment. Another class of person, the patent-medicine vendor, was also alive to the limitations of the healing art, and sought to take advantage of the credulity of the public. As the law stood, anyone without special knowledge or qualification could produce and offer a nostrum for sale. The serious aspect of "patent medicines" was that many sufferers from recoverable diseases resorted to advertised drugs without ever having consulted a doctor, and wasted valuable time while they passed beyond medical aid. The danger was a real one, and it was time, Prof. Murray Lyon said, that the public awoke to the fact and took into its own hands some means of controlling this trade.

The Attack on Porridge.

Resentment against Prof. Mellanby's alleged attack on a national food-stuff is subsiding. Odd phrases from the Sheffield researches on cereals had been snatched from their context, and the fighting spirit was aroused by headlines in the newspapers denouncing oatmeal as a poison and porridge as a dangerous breakfast dish. Reason has prevailed, and it is seen to be possible to accept without emotion the statement that oatmeal, like other cereals, including barley and rice, contains a substance which hinders the formation of bone in young animals. This substance, the nature of which is obscure, may be regarded as a poison in so far as it interferes with the deposition of lime in bone-formation, thus predisposing children to rickets, and, in adults, at least disturbing the normal "give and take" of lime salts between the blood and bones. An antidote to this "poison" is happily within easy reach in vitamin A of animal fats. Prof. Mellanby, himself a loyal Scot, is naturally aware that thousands of his hardy compatriots have been raised on a diet consisting largely of oatmeal. A famous Edinburgh divine, who died only a few years ago, once told how as a University student 50 years before, he had lived in a garret and eaten nothing but oatmeal and salted herring. Indeed, the mid-term holiday in some Scottish universities is still called "Meal-Monday" because it dates from the time when students went home to have their meal-bags replenished. No doubt the abundant supply of vitamin A in milk, eggs, and fatty fish will continue to protect the porridge-eating Scot from rickets or worse.

University of Glasgow.

Among those on whom the University of Glasgow will confer the honorary degree of Doctor of Laws, on June 24th, are two distinguished surgeons, Sir John Bland-Sutton, President of the Royal College of Surgeons of England, and Mr. Martin T. Tuffier, professor of surgery at the University of Paris.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

The Dublin Hospitals and State Aid.

A BRIEF discussion arose in the Dail last week out of the vote of £4728 for hospitals and infirmaries. Mr. Burke, Minister for Local Government, pointed out that the hospitals receiving grants from this charity fund had gained a statutory right to the grants at different times and under peculiar conditions. Some of those institutions carried on in anticipation of getting these grants, and it would be a very serious matter to cut them off without having a thorough inquiry into the whole matter. It was a question for a Commission or a Consultative Council, and he hoped at an early stage to set up such a Commission or to consult with such a Council. In the discussion which followed it was stated that it was becoming a matter of increasing difficulty for poor people to obtain admission to the Dublin hospitals, owing to the necessity of keeping paying beds if the hospitals were to keep open at all. From all sides of the House there was a desire that the inquiry should deal with the whole question of the upkeep of the hospitals. It was also suggested that the question whether the number of hospitals should be reduced should be considered.

Society of Surgeons.

Last week the Society of Surgeons of the United Kingdom held its first meeting in Dublin, under the presidency of Sir William Taylor. Some 80 surgeons attended. The mornings of April 30th and May 1st were devoted to general discussions and each afternoon was spent in operations at the several hospitals. On Thursday evening the surgeons dined together in the Royal College of Surgeons. The congress passed off very pleasantly, and the visitors appeared to have enjoyed their first visit to Dublin.

Treatment of Crippled Children.

Sir Robert Jones gave an address last week at the Orthopædic Hospital, Dublin, on the Treatment of Crippled Children in Open Air Hospitals. He expressed his admiration for the work and results he had seen in the hospital, and said that in Great Britain they had probably 100,000 cripples, and if a great national effort were made and they succeeded in getting the help they required, 90 per cent. of these cripples could be made useful assets. A large proportion of the cases was due to tuberculosis and rickets. Nearly all cases of bovine tuberculosis in children were due to direct poisoning by milk. One out of ten specimens of milk delivered at doors was infected with tubercle bacilli. Having emphasised the importance of fresh air, sunlight, and proper diet for children, he said the reason there was so much deformity in the country was that crippled children were not treated early enough; there was also the important matter of continuity of treatment. In any scheme that could be adopted it was essential that they should have a hospital in the country.

Irish Medical Association.

At a meeting of the Council of the Irish Medical Association held recently, Prof. F. C. Purser, of Dublin, Vice-President of the Association, was nominated as President, and Dr. H. T. Warnock, of Donegal, as Vice-President, for 1925–26.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Weak Points in Modern Medical Literature.

BEFORE the German Surgical Congress held recently in Berlin Prof. Sauerbruch delivered an address on certain faults in modern medical writing. He said that in his opinion the number of medical essays published was much too large, the reason being that the younger medical men engaged in scientific work were endeavouring to recover the time lost through the war and the after-war period and that professors in desiring to attract attention to their own clinics or hospitals stimulated their assistants to write. The result was that the work was often done quite superficially, no care was applied to the style, new technical terms were invented unnecessarily, and for the purposes of "padding" results of former investigations were repeated in the text. Concerning the work itself, there was a marked tendency to over-estimate the results of experiments in animals and in laboratories and to apply such results to the human species. He explained that medicine had now reached a crisis, new problems coming to the foreground, and the question of the human constitution was becoming more important than bacteriological and chemical considerations which were formerly the principal objects of medical investigation. He then drew attention to text-books for students. The more surgery is divided into special branches, he said, the more difficult it will be to write a good text-book. Only surgeons with a thorough knowledge of the different branches of surgery ought to undertake that task; he held that it was not desirable that text-books should be written by the collaboration of several authors who might hold divergent views, as such a compilation led to confusion in the student's mind. In handbooks which give the results of modern researches to readers who are already familiar with the subject the collaboration of several authors is necessary. Prof. Sauerbruch's opinion met with the approval of the members and was in the discussion supported by Prof. Bier, of Berlin, who declared that by exclusive experimental and laboratory work the younger generation had lost a good deal of their capacity of observation. He recommended to them to read the works of surgeons of former times who, although being apparently less scientific than the younger medical men, were nevertheless excellent observers from whom they might still learn very much. He mentioned the works of Sir Astley Cooper, of Prof. Dieffenbach, and others.

A Case of Auto-Suggestion.

Dr. Zehden recently showed to the Berlin Medical Society a man who gives public performances of his power of auto-suggestion in music-halls. This man had been wounded in the war, and in the army hospital he noticed that morphia which was administered to him had no effect. By auto-suggestion he succeeded, however, in becoming totally insensible to pain, so that a shell splinter could be removed from his leg without anæsthetics. After the war he turned this faculty of auto-suggestion to account, and in public performance allowed members of the audience to pierce his arms and legs with ordinary unsterilised hat-pins. Dr. Zehden reported that in the state of induced insensibility the man not only does not feel any pain but that neither hæmorrhage nor infection develops. Infection happened only once when, in a performance before a medical audience in Spain, he was unable to reach the state of total insensibility. The man, who calls himself To-Rhama, being the Sanscrit word for self-conqueror, does not show any symptoms of hysteria; his insensibility does not occur in a state of hypnosis but he remains awake and speaks and hears. Another remarkable phenomenon is that the man in that stage can dilate and contract his pupils voluntarily. The man was then pierced with a pin by members of the society and it was noted that not a drop of blood appeared on the pin.

Papilloma of the Stomach.

Before the Berlin Surgical Society Dr. Bötticher lately reported a case of papilloma of the stomach. The patient was a woman, 72 years of age, who had consulted him four years ago for slight gastric troubles. On palpation the presence of a growth of the size of a walnut was ascertained which was, of course, believed to be cancer. Operation was declined and the patient was not seen by him for four years. In 1924 she came again, in an emaciated condition, the growth now being the size of an infant's head. Laparotomy was performed under local anæsthesia, and on opening the stomach an enormous tumour attached by a broad base to the fundus of the stomach was found and removed with some difficulty. Microscopical examination proved that the tumour was papilloma. It was remarkable that the symptoms caused were relatively slight. Papilloma of the stomach is extremely rare, only five cases have hitherto been described, and in none of them had the diagnosis been made previous to the operation. Some authors are of opinion that papilloma develops from gastric ulcer; such was not the case in this patient. The danger to the patient lies either in the growth by its size producing an obstruction of the pylorus, or in hæmorrhage, or in eventual carcinomatous degeneration. Removal of the growth is, of course, indicated in every case and must be a radical one to avoid relapse.

A Question of Medical Etiquette.

It is an old custom for medical men to refrain from charging fees for attendance on their professional brethren and their families. This was justified at a time when the number of medical men was so small that personal relations existed between them and the system worked on a satisfactory quid pro quo basis. Times have, however, changed; the large number of doctors, at least in great cities, has made this system impossible, especially as a great number of medical men in this country, probably more than abroad, are specialists, whose services the general practitioner can seldom repay in kind. The custom has therefore grown up of recent years for the professional patient to recognise his medical attendant, if not a personal friend, by some gift, monetary or otherwise. A remarkable law suit concerning that question has recently taken place before a court in a great city of Northern Germany. An ophthalmologist attended another medical man suffering from severe iritis. He saw the patient 20 times at the latter's home and about 300 times in his consulting-room. Owing to the great amount of trouble connected with the case he sent a bill for M.1700, a rather moderate charge. The medical patient declined to pay, not because the charge seemed to him too high but because he held that it was the time-honoured custom among medical men not to charge fees to each other. The court asked for the opinion of the Medical Chamber, and when the latter declared that it was indeed contrary to custom to charge fees to a professional brother the court found for the defendant. This decision led to a discussion in the medical press. It is alleged that the old custom can no longer be maintained as conditions have totally changed. Some specialists are indeed consulted by medical men and their families to such an extent that they have little time to devote to other patients. A well-known specialist for infants' diseases stated that about one-third of his clientèle belonged to the families of medical men; another reported that he had been called at night to a medical colleague residing in a remote suburb to perform an urgent operation and that the considerable expenses connected with that case had never been recovered. The opinion of the Medical Chamber is not in agreement with the present condition of the medical profession.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following are some of the health statistics for the year 1924 of a group of local government districts of varying status :—

Name of district.	Mid-year population (R.-G.).	Birth-rate.	Death-rates per 1000 of the population.				Death-rates per 1000 births.		
			All causes.	Tuberculosis.	Cancer.	Resp. diseases with influenza.	Neonatal mortality.	Infant mortality.	Maternal mort. from childbirth.
Poole B.	45,150	18·0	11·6	1·04	1·1	1·9	40	66	6·1
Woking U.D. ..	26,440	14·6	9·1	0·64	1·1	1·3	—*	35	2·5
Guildford B. ..	25,720	15·3	12·3	0·97	1·0	2·3	—*	52	2·5
Guildford R.D. .	20,060	14·6	10·9	0·65	1·7	1·8	—*	32	6·3

B., Borough. U.D., Urban district. R.D., Rural district.
* Information not given in the report.

Borough of Poole.

Dr. R. J. Maule Horne reports that Poole is growing rapidly. Over 500 houses were built last year and the cleansing services have a difficulty in keeping pace with the growth, which tends to be uncontrolled. Thus, houses in some cases grow up along an old cart track. The number of cesspools cleared by the department has increased from 411 to 434. Dr. Horne strongly advises the establishment of a regional advisory planning committee, to include representatives of contiguous districts and private estates. He emphasises the climatic advantages due to the shelter of the Purbeck Hills and the equability induced by the extensive sheet of water in the harbour, whence freedom from the damp sea-mists of the coast-line is obtained. He has a note of warning to sound with regard to the destruction of the pines, which are Poole's chief pride. Unemployment has fallen from a monthly average of 938 in 1922 and 626 in 1923 to 366 in 1924. There is, however, a large amount of quayside unskilled labour. A free open-air tidal swimming-bath is well used during the summer months, and Dr. Horne urges the provision of up-to-date well-equipped salt water swimming-baths which would not be subject to seasonal closure. Some effort is made to control mosquitoes by spraying the breeding-places with paraffin. The public analyst reports that, of 11 samples of butter examined, nine contained boric acid and a high percentage of water. Dr. Horne shows that while infant mortality has been declining, there has also been concomitantly a great decrease in the deaths of children from 1 to 5 years of age. The supervision of boarded-out children has been handed over by the board of guardians to the Maternity and Child Welfare Department.

In the school report Dr. Horne points out that verminous conditions are much too prevalent. The dental surgeons inspected 3209 children and found that 2131 required treatment. Only 637 of these actually received treatment at the dental clinic. The total amount received in fees in reduction of the gross cost of the school medical service was £33 10*s*., including £8 12*s*. for dental treatment. The scale of fees has now been in operation for a year, and experience has shown that the chief branch of the work of the clinic to suffer from the imposition of a charge has been the care of the teeth.

Woking Urban District.

Dr. R. W. C. Pierce says the low infant mortality-rate of the last two years speaks well for the work inaugurated by the Woking Health Society and now carried out by the council. The council pay the Health Society a yearly grant of £50 for nursing infectious diseases among children. The Woking Health Society also maintains an excellent maternity home, in which last year there were 86 confinements, while 11 miscarriages and two antenatal cases also received treatment. No necessitous cases are refused, and 12 of the patients admitted were paid for by the council. The small cottage hospital, provided by voluntary contributions, has proved quite inadequate and an extension, consisting of two six-bed wards, three single-bed wards, and additional staff accommodation, is in progress. The clean milk movement makes progress. All the dairy cows are examined quarterly by the veterinary inspector, Mr. A. C. Wild. One case of generalised tuberculosis and a " waster " were found among the cows inspected (averaging 438), and destroyed. Considerable trouble was experienced with tents and vans on the commons. In all 107 tents and vans were removed, and application has been made to the Ministry for powers to make by-laws.

Guildford Borough and Guildford Rural District.

Dr. Pierce is also medical officer of health of these two districts. Nine cases of encephalitis lethargica were notified in the borough, but three of them, one fatal, belonged to other districts and were notified from the County Hospital. The ages of the six borough cases varied from 10 to 43. The patients who recovered were aged 10, 10, and 18 respectively, and the patients who died were aged 36, 42, and 43. In the rural district four cases were notified, three of which died, aged 40, 59, and 1½ respectively. The fourth case, a woman of 48, recovered. There appeared to be no direct connexion between any of the cases, either in the borough or the rural district. The number of new houses erected in the borough was 242, with State assistance for 72 council houses and 98 privately erected; while in the rural district 169 houses were built, of which 36 council and 19 privately built received State assistance. The milk question is receiving attention, and the clean milk competition conducted by the Surrey County Council has been taken up by many of the dairymen in the rural district. A prosecution and conviction for black smoke from a brewery chimney in the borough led to an appeal, but the decision of the magistrates was upheld and the appeal dismissed.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED APRIL 25TH, 1925.

Notifications.—The following cases of infectious disease were notified during the week, namely:—Small-pox 170; scarlet fever, 1530; diphtheria, 779; enteric fever, 28; pneumonia, 1136; puerperal fever, 62; cerebro-spinal fever, 12; acute poliomyelitis, 5; acute polio-encephalitis 1; encephalitis lethargica, 54; dysentery, 11; ophthalmia neonatorum, 117. There were no cases of cholera, plague, or typhus fever notified during the week. The number of small-pox cases showed an increase of 35 over the number for the preceding week. One case was notified from the County of London (Bethnal Green); 55 from Derbyshire (Derby C.B., 41); 5 from Leicestershire (Leicester C.B.); 22 from Northumberland; 17 from Notts (Mansfield Woodhouse, 10); 7 from Warwickshire; 34 from Yorks, North Riding (Middlesbrough C.B.); Yorks, West Riding, 3 (Rotherham).

Deaths.—In the aggregate of great towns, including London, there were 4 deaths from enteric fever, 122 from measles, 7 from scarlet fever, 110 from whooping-cough, 40 from diphtheria, and 139 from influenza, as compared with 162, 221, 242, and 281 in the four preceding weeks. In London itself the deaths from influenza numbered 18, from whooping-cough 26, and from diphtheria 9.

SMALL-POX IN LONDON.

Up to May 6th, 6 cases of small-pox have been notified in London: 1 from Lambeth and 5 from Bethnal Green. The Bethnal Green cases all occurred in one family, of whom the 3 children were unvaccinated, the father and mother having been vaccinated in infancy. The Lambeth patient was unvaccinated. It is understood that all cases are of the prevalent mild type.

The Services.

ROYAL ARMY MEDICAL CORPS.

Col. F. Ashe (late R.A.M.C.) retires on ret. pay.

Lt.-Col. and Bt. Col. H. Ensor to be Col., vice Col. F. Ashe.

Lt.-Col. D. S. Skelton is secd. for serv. under the Colonial Office.

Maj. T. J. Hallinan retires, receiving a gratuity.

Maj. S. McK. Saunders retires on ret. pay.

Capt. W. H. Dye resigns his commn.

TERRITORIAL ARMY.

Maj. L. A. Harwood to be Lt.-Col. and to command 167th (City of London) Fld. Ambulance.

Capt. J. P. McGreehin (late R.A.M.C.) to be Capt.

Lt. D. F. Hocken relinquishes his commn.

ROYAL AIR FORCE.

Flight Lt. C. P. Barber is granted a permanent commission in the rank stated.

Flight Lt. D. J. Jones relinquishes his temporary commission on account of ill-health.

INDIAN MEDICAL SERVICE.

Capts. Sahib Singh Sokhey, A. Seddon, and R. V. Martin to be Majs.

Fakhar-ud-Din to be tempy. Lt.

Capt. Mahdo Prasad to be restored to the active list from the temp. non-effective list.

KING EDWARD VII.'S CONVALESCENT HOME FOR OFFICERS.

The King has approved the reappointment of the undermentioned to the Consulting Staff of King Edward VII.'s Convalescent Homes at Osborne, Isle of Wight, for Officers of H.M. Navy, Army, and Air Force: Sir C. Wallace, Sir H. Waterhouse, Mr. G. E. Gask, Sir W. H. Willcox, Dr. C. H. Miller, Dr. H. S. French, and Dr. H. M. Fletcher.

BELGIAN CONGRESS OF STOMATOLOGY.—To celebrate the twenty-fifth anniversary of the Société Belge de Stomatologie, an international congress will be held in Brussels from July 11th to 14th. Lectures and practical demonstrations will be given, and leading specialists will deal with such subjects as focal infection, pathology and treatment of cancer of the mouth, vitamins, and so forth. The membership fee is 50 francs, which entitles the member to a copy of the Proceedings of the congress. Further information may be obtained from the joint secretaries, Dr. René Boisson, 35, rue Belliard, and Dr. Polus, 18, rue du Commerce, Brussels.

Correspondence.

"Audi alteram partem."

THE BATEMAN FUND.

To the Editor of THE LANCET.

SIR,—Have the bowels of compassion of the medical profession been utterly and completely resected? Surely some unorthodox surgeon has been stalking about the land with a thousand sparkling scalpels shimmering around him? He seems to have alighted on about 99½ per cent. of the medical profession and to have removed therefrom the compassionate organs above mentioned!

So far as I can make out, the contributions to this fund for a professional brother in trouble amount to about the same as the single contribution of the proprietors of THE LANCET. And this from the whole of the medical profession of Britain!

Dr. Bateman—a complete stranger to me—was cleared of the charge against him by the courts. We all know—or should know—what he has had to go through. We also know—or should know—that any one of us at any moment may be at the mercy of an ignorant jury. And yet all we can find between us is £250!

I enclose another small contribution in the hope that it may stimulate others to help a colleague whose name a British court of justice has cleared.

I am, Sir, yours faithfully,
A. GRAHAM-STEWART.

Cliftonville, Margate, May 1st, 1925.

*** We trust that the merits of this case will commend themselves promptly to more of our readers. The proceedings in the Court of Criminal Appeal will be found substantially reported in THE LANCET, Feb. 14th, 1925. Remittances should be forwarded to the Manager of THE LANCET, 423, Strand, W.C. 2, and made payable to the "Bateman Fund Account."

THE TREATMENT OF NON-PIGMENTERS BY LIGHT.

To the Editor of THE LANCET.

SIR,—In the course of a paper on light treatment in surgical tuberculosis read before the Tuberculosis Society, at their meeting held here a short while ago, Sir Henry Gauvain stated that those children who easily become pigmented under the influence of sunlight usually do well, while those who do not so readily pigment derive less benefit from the treatment, and sometimes are unable to endure it. Now pigment in the skin probably acts as a light filter, cutting out certain rays and allowing others to pass through; and since the pigmenters do well in spite of pigmentation it would seem that the benefit is derived from rays which are not excluded by the pigment. The rays which are intercepted by the screen of pigment are probably those which cause local inflammation and even constitutional disturbance; the consequence being that the pigmenters are able to receive a large dose of the healing rays, while the non-pigmenters cannot do so because they are upset by the rays which cause inflammation. It therefore seems desirable to seek for a means of excluding the latter rays while allowing the others to act with full effect on the children whose skins do not pigment under the action of light.

Many years ago, when summers were sometimes really hot, I tried the experiment of exposing to the full force of the sun's rays the greater part of my arms during a boating holiday. Round one arm I had stained a broad band of skin a pale shade of brown. The result of several days' exposure was to produce a state of inflammation and œdema above and below the stained zone, but the zone itself remained normal.

The moderate degree of staining had therefore completely protected the skin from the inflammatory rays.

My object in writing this letter is to persuade those who are applying the light treatment to sufferers from tuberculosis to try on those persons who do not appear likely to pigment well the effect of lightly staining the skin before exposure to the rays. In my experiment, so well as I can remember after so long an interval of time, I employed strong coffee to stain my arm, but I would suggest as a convenient substitute a weak solution of permanganate of potash. The face, of course, need not be stained since it can be shaded, nor the hands, accustomed as they are already to exposure.

I am, Sir, yours faithfully,

LOUIS COBBETT.

Pathological Laboratory, University of Cambridge,
April 28th, 1925.

THE INFLUENCE OF TOBACCO.

To the Editor of THE LANCET.

SIR,—There is some confusion between tobacco and tobacco smoke concerning the content of nicotine. Some writers deal with the former, others with the latter. Heinz[1] says that only about one-sixth of the tobacco content appears in the smoke, and the *smoke*, according to Cow,[2] contains 1·5 per cent. of nicotine. The quantity absorbed varies greatly with the extent to which the smoke is inhaled. In a recent issue of the *Presse Médicale*, dealing with tobacco as a cerebral poison, Binet[3] refers to three manifestations occurring in animals on the administration of nicotine: cerebral congestion, cellular lesions, and memory troubles, but we are told very little about the quantities necessary to produce these results. To be of any value in their applicability to man experiments of this sort should be performed with quantities of nicotine which are in some way equivalent to those in the blood of heavy smokers, weight for weight. Man uses tobacco chiefly for its effect on those faculties which animals do not possess, and he easily acquires tolerance, as pointed out by Cow.[4] This is probably an example of the Lamarckian principle of the inheritance of acquired characters. The amount of 1–2 mg. of nicotine per litre of blood is not an excessive estimate in the case of a heavy smoker, and the withdrawal of that component from the blood may lead to troublesome symptoms, causing depreciation in efficiency as the overdose does in the light smoker.

We see inveterate smokers on the golf links, ounce-a-day men some of them, who are perfectly fit and apparently insusceptible to fatigue from much physical work. Considerable reduction of their allowance of tobacco is frequently followed not merely by discomfort but by decline of form. That the work of skeletal muscle like that of the heart may be enhanced by nicotine is quite compatible with the results obtained by Langley[5] in this domain. A scratch player at golf of my acquaintance suddenly stopped smoking altogether—he had been accustomed to almost an ounce a day—and, to use his own expression, "went to pieces" as a result. A man like this probably has an ordinary blood content of nicotine of 1 or 2 mg. per litre. The experience of this player so far looks like an argument in favour of abundant tobacco for golfers; but he persevered with his abstention until his form returned, and he thought it was even slightly better than before. The margin of difference, however, from the nicotine standard was too slight to warrant continued privation. Others, who for some reason abruptly give up smoking, complain that their faculties of memory and judgment are for a while impaired, as is their skill in various performances.

The symptoms produced by an overdose in the light smoker, such as insomnia, fast pulse, throbbing at the temples, indicate cortical and bulbar effects. The cardio-inhibitor tone is depressed, as is that of the vaso-motor centre somewhat later. These effects, while notably transient, are undoubtedly greater and last longer in the case of one smoking in a crowded room or theatre than in the open air, and it is a matter of importance in determining the influence of tobacco to attend to the hygienic conditions in which it is used. The absorption of the accessory substances such as pyridine bases as well as of nicotine, is probably greater in a confined space than in the open, and their elimination, shown by Straub[6] to be a slow process in general, is possibly still further slowed by such conditions. The point is one calling for study.

One thing I can affirm with confidence, something which must have a bearing on the action of nicotine on any tissue, is the need of pretty large doses of the drug in perfusion experiments in order to produce appreciable results in disturbance of the heart's rhythm and work, in the toad and frog. Small doses as used by Clerc and Pezzi for the dog's heart may cause change of rate, and of electrocardiogram in the mammal; but it requires a concentration of about 0·2 per cent. or more to cause arrest of beat, dissociation, and reversal. Further, at a certain stage of the action of nicotine the muscular functions are enhanced[7] owing to a dual effect on muscle-fibre and augmentor nerves, so that the ventricular systole is able to overcome a greater resistance to output than previously, and the work done in a certain time is increased. Lastly, the heart recovers quite well from prolonged action of the alkaloid.

Proceeding to the central nervous system, one may expect to find there also a fair amount of resistance to the influence of nicotine in man as in animals. One part of the investigation of the problem in man might suitably consist of observation of the effects produced by increase, over short periods, of the usual quantity of tobacco for the light smoker and diminution for the heavy smoker. These are more susceptible to the influence of change in their respective directions than would be the moderate smoker in either direction. The symptoms of vertigo, nausea, depression, &c., produced in the non-smoker do not take one very far, any more than in the case of animals.

The physiological effects of tobacco, as our present knowledge reveals them, are not sufficiently deleterious to counter-balance the benign influence of the drug in other respects. It may be abused, of course, but so may food, and this latter form of abuse is, in my opinion, responsible for greater evils than those resulting from the abuse of tobacco.

I am, Sir, yours faithfully,

D. T. BARRY, F.R.C.S. Eng., M.D.,
Physiology Department, University College, Cork.
April 25th, 1925.

CHARGES AGAINST PENSIONS OFFICIALS.

To the Editor of THE LANCET.

SIR,—I notice in your issue of April 18th my name is mentioned by your Parliamentary correspondent in connexion with charges against pensions officials as being the hon. and gallant Member for Salford. I write to say that I had nothing whatever to do with these charges and that I have always been Member for the Salisbury Division of Wiltshire.

I am, Sir, yours faithfully,

HUGH MORRISON.

9, Halkin-street, Belgrave-square, S.W. 1,
April 29th, 1925.

*** We greatly regret the inadvertence, which occurred obviously in transcribing the name from an alphabetical list of constituencies.—ED. L.

PREMATURE SEPARATION OF THE PLACENTA.

To the Editor of THE LANCET.

SIR,—In your report last week of the proceedings of the recent British Congress of Obstetrics and Gynæcology much of necessity has been omitted, and it is not surprising my remarks on the premature separation of the placenta do not appear. But you found space for Prof. B. P. Watson's opinion "that the primary condition was hæmorrhage into the uterine wall, and the separation of the placenta was a mechanical result of that"—an opinion which Prof. Watson thought was accepted. As, however, I do not know that all obstetric teachers and thinkers are agreed on this point, and lest your readers should imagine they are, I venture to put before you some reason for the belief that the separation of the placenta is primary, and that the hæmorrhages into the uterine wall are secondary to the increased and rapidly occurring uterine distension. Above all else is this, that the pathological changes which the uterine wall undergoes in accidental hæmorrhage are peculiar to cases in which the bleeding is concealed. I believe I am right in stating that the necrosis of the uterine wall on which the late Mr. Gordon Ley laid such stress, and the hæmorrhages into its substance, only occur when the blood extravasated beneath the placenta is prevented from escaping from the uterus. However this retention be caused, it is clear that as a result of the bleeding the uterus becomes more and more distended until the bleeding is checked. In bad cases the uterine distension is so great that the peritoneum covering the uterus is split in many places, and the blood (escaping from the high pressure arterioles) ploughs a way through the musculature, even reaching the peritoneal sac or invading the connective tissue within the broad ligaments. That the intra-uterine pressure is greatly raised is clear not only from the pathological findings at operation or post mortem, but also by the clinical finding that if the membranes be ruptured a further great loss of blood occurs with rapid death of the patient (Gordon Ley).[1] But when the blood escapes from the uterus, when the accidental hæmorrhage is apparent, such a distension of the uterus does not occur, and the changes—the necrosis and the hæmorrhages—of the uterine wall are not found. I do not know of a single case in which such have been reported.

And were Prof. Watson correct in his opinion, I submit that pathological changes in the uterine wall—e.g., at Cæsarean section, and apart from concealed accidental hæmorrhage—should occasionally be found. But is not the case otherwise? Moreover, Prof. Watson should show us how the hæmorrhages—the small ones scattered throughout the uterine wall, as the beautiful lantern slide shown by Prof. Whitridge Williams displayed—are caused. To attribute them to a preceding toxæmia scarcely holds in those cases of concealed accidental hæmorrhage, which from time to time occur without any sign of such a toxæmia. That a toxæmia or an anuria should arise subsequently to concealed accidental hæmorrhage is explained (in my view) by the effect of the uterine distension on the intra-abdominal pressure, and so on the other maternal viscera. In such cases the uterus is mainly prevented from bursting by the increased tonicity of the muscular sheets forming the roof, walls, and floor of the abdomino-pelvic cavity. It is reasonable to believe a great rise of extra-uterine pressure within the abdomen occurs, and that this must affect the flow of blood through the visceral—e.g., renal—capillaries.

As to the cause of premature separation of the placenta, I believe trauma plays a greater part than is at present allowed. The question is, What do we mean by trauma? Are we to limit this to such accidents as falling downstairs or being kicked on the abdomen by a horse? Or may such acts as carrying in the breakfast things play a part? It is interesting to note that in some of the cases reported by Gordon Ley the disease began in the morning—at 9 or 10 o'clock. In other cases, the disease seems to have begun during the night. A question in my mind is how often coitus in the latter weeks of pregnancy may occasion this accident. The conception is supported by the occurrence of the disease in primigravidæ (that is, in women with young husbands); by the fact that coitus late in pregnancy is not uncommon; and by the superstition that coitus just before labour facilitates delivery.

I am, Sir, yours faithfully,
R. H. PARAMORE, F.R.C.S. Eng.

Rugby, May 4th, 1925.

NURSING HOMES (REGISTRATION) BILL.

To the Editor of THE LANCET.

SIR,—You were good enough to allow me in your issue of April 25th to draw the attention of the profession to this Bill and its likely pernicious effect on all concerned in those instances where doctors received patients into their private houses. May I now draw attention to another aspect—that is, how it will affect the question of professional secrecy if the Bill goes through in its present form.

In accordance with Section 1 every nursing home will have to be registered or be closed down by June 1st next! If it is approved and registered then under Section 5 the Minister of Health will issue regulations prescribing the registers to be kept and the particulars as regards patients (names, addresses, accident or disease, treatment, result, &c.). Reports also will have to be made to the Ministry on these matters. Under Section 8 these registers and reports will be subjected to inspection and review by the medical officer of health or (and) a State-registered nurse appointed for the purpose. Under Section 9, if in order to protect professional secrecy the doctors refuse to keep these registers or to allow of this inspection and criticism, heavy fines can be inflicted on the proprietors, and if still recalcitrant the licence can be withdrawn and the home closed down.

At the present moment these homes are voluntary; the patients go there voluntarily; the doctors are voluntary and are paid by the patients. There is not a single vestige of State interference or supervision apparent. Everywhere, other than possibly in London, one hears that these homes are valued and those who conduct them are well known and respected by our profession. So-called homes die from want of material.

Is the profession willing—through apathy, indifference, or otherwise—to allow this Bill to go through without drastic amendment, with a further enroachment by the State on professional secrecy and professional liberty? If not, may one venture to urge every doctor interested—and there must be thousands—to immediately protest to their Member of Parliament, the B.M.A., in the press, and otherwise. The promoters desire the Government to take over this Bill and to make it a Government measure. There is no time to be lost.

I am, Sir, yours faithfully,

Hove, May 4th, 1925. E. ROWLAND FOTHERGILL.

"UNNECESSARY" OPERATIONS.

To the Editor of THE LANCET.

SIR,—In discussing Lord Riddell's paper, "The Legal Responsibility of the Surgeon,"[1] you referred to possible operations not necessary for conserving or improving the health of the persons seeking them, and to the "medical welfare" of the patient as the test by which the lawfulness or otherwise of a proposed operation must be determined. The question of what the medical welfare of the patient may require must be for the surgeon to answer according to the particular circumstances of the case, and the necessity need not be such that immediate surgical interference is "necessary" in the ordinary sense of the word. It is a question of an honest endeavour to act rightly in the true interest of the patient. Here, for example, is an instance where an operation is rightful without being necessary, and the situation must often have occurred. A man is about to go for an indefinite period to a country where he is uncertain about obtaining the best medical advice. He consults his doctor as to certain symptoms and is told of the possibility, rather than the probability, of impending appendicitis, whereupon he decides to have his appendix removed before leaving London, where he is familiar with and has confidence in the conditions of surgery and nursing. When these operations are performed there cannot be any sequel to prove that they were necessary lest worse should happen, but they are rightly undertaken in the interest of the patient's "medical welfare." A more difficult problem would be propounded by a patient who, having never suffered from anything indicative of appendicitis, but being about to go beyond the reach of surgical skill, should demand the operation as a precaution. Who would be prepared to say that such an operation ought to be refused as prejudicial to the public good and so contrary to public policy? Yet I think the intending patient would not readily find a surgeon to fall in with his wishes. If certain general principles are admitted as governing such cases, their application to concrete examples must be left to the conscience of professional advisers.

Medical News.

UNIVERSITY OF CAMBRIDGE.—At recent examinations the following candidates were successful:—

DIPLOMA IN MEDICAL RADIOLOGY AND ELECTROLOGY.

Part I., Physics and Electrotechnics.—Elizabeth M. Bird, John F. Bromley, Edward H. P. Cave, Margaret R. Clark, Beatrice L. Collins, William C. Fothergill, Eric D. Gray, John L. A. Grout, Adangaprathoo O. Jacob, Pami H. Jhangiani, Montagu H. Jupe, Peter J. Kerley, Athanase Lambadarides, Colin F. Macdonald, Ethel M. Magill, Phani B. Mukerji, Iqbal S. Nalwa, John O'Sullivan, Ketih A. Piper, Ernest J. H. Roth, Narendra S. Sodhi, Dulcie C. Staveley, Herbert M. Strickland, Cyril G. Whorlow, and Frederick E. Wynne.

Part II., Radiology and Electrology.—Edward H. P. Cave, Robert V. Clayton, William C. Fothergill, Adangaprathoo O. Jacob, Colin F. Macdonald, Cusack J. K. O'Malley, John O'Sullivan (distinction), Dulcie C. Staveley, Herbert M. Strickland, Richard S. Topham, and Cyril G. Whorlow.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—At a meeting of Comitia of the College on April 30th, Sir Humphry Rolleston, the President, in the chair, the following candidates, having passed the required examination, were admitted Members:—

Frederick M. B. Allen, Herbert A. Brookes, Morris J. Cohen, Leslie B. Cole, Robert H. Cooke, Macdonald Critchley, John N. Cruickshank, Charles F. Harris, Amy Hodgson, William A. Lister, Arthur S. MacNalty, David C. Muir, Robert Platt, Thomas D. Power, D'Arcy J. Prendergast, Jeffrey Ramsay, Chennagiri K. Rau, and Ambrose Spong.

The following Members were elected to the Fellowship:—

Robert Fortescue Fox, Athelstane Iliff Simey, Ivor Jones Davies John Davis Barris, Henry Harold Scott, Joseph Godwin Greenfield, George Riddoch, Alfred Bertram Soltau, William John Adie, Frederick George Chandler, John William McNee, and Bernard John Hart.

Licences to practise were conferred upon 138 candidates, of whom 19 were women, who have passed the Final Examination of the Conjoint Board and have complied with the by-laws of the College. The following are the names and medical schools of the successful candidates:—

C. S. Anderson, St. Mary's; W. A. Barnes, Cambridge and St. Bart.'s; St. C. E. J. Barrett, Middlesex; I. C. P. Beauchamp, Cambridge and Guy's; J. R. Beagley, St. Bart.'s; Diana J. K. Beck, Royal Free; P. R. T. Becker, Cape and Guy's; Elizabeth E. Benson, Bristol; C. P. Blacker, Guy's; W. R. Bonner-Morgan, Cardiff and St. Bart.'s; E. H. Boodrie, Calcutta and St. Mary's; Duncan de C. Boxill, Long Island Coll. and St. Mary's; P. G. Brain, London; M. K. Braybrooke, St. George's; R. B. Brew, Univ. Coll.; C. W. Brook, Cambridge and St. Bart.'s; G. M. Brooks, Birmingham; M. F. Butler, Guy's; L. I. M. Castleden, St. Bart.'s; Enid A. Ceiriog-Cadle, Royal Free; M. Chandra, Punjab and St. George's; R. J. K. Chattey, Middlesex; J. E. Church, Cambridge and St. Bart.'s; Hilda A. Cohen, Cardiff; Jean Cooper, Punjab and Royal Free; Catherine A. Cowan, Royal Free; P. V. Crameri, Univ. Coll.; D. P. Crawford, St. Thomas's; D. A. L. Crawshaw, Guy's; Victoria M. Crosse, Royal Free; G. P. Crowden, Univ. Coll.; J. Crowther and J. Cumming, Manchester; R. N. Curnow, St. Bart.'s; R. R. Dalling, Liverpool; H. E. Daniel, Cardiff and St. Bart.'s; R. K. Debenham, Cambridge and London; A. E. De Chazal, Univ. Coll.; J. D. Dillon, St. Bart.'s; W. H. A. Dodd, Liverpool; A. S. M. Douglas, St. George's; J. L. C. Doyle, St. Bart.'s; G. I. Evans, Manchester; P. F. Evans, London; Christabel S. Eyre, Charing Cross; C. R. Fielding, Manchester; F. J. T. Foenander, Middlesex; C. A. Francis, Cambridge and St. Bart.'s; D. B. Fraser, St. Bart.'s; H. E. Gamlen, Durham; A. W. Gardner, St. Bart.'s; J. H. Gibbens, Cambridge and St. Thomas's; G. D. Gillbard, Middlesex; A. Gompertz, Durham; R. T. Goodyear, Cambridge and Liverpool; D. R. Grant, Alberta and Guy's; G. S. Hale, St. Bart.'s; S. Harris, Oxford and St. Thomas's; J. H. Hartland, Birmingham; F. C. Haward, St. Thomas's; Marjorie F. M. Hayward, London; H. L. Heath, Birmingham; Catherine M. Hext, London; H. F. Hiscocks, St. Bart.'s; F. D. M. Hocking, Middlesex; R. G. Hodder, St. Thomas's; H. B. Howell, St. Bart.'s; J. E. Howie, Liverpool; W. Hughes, Middlesex; J. T. Hunter, St. Bart.'s; J. S. Jacobsz, Cape and Guy's; Maurice E. M. Jago, Guy's; L. E. Jones, Cardiff and St. Thomas's; L. R. Jones, Guy's; W. H. M. Jones, Cardiff; B. Kaplansky, Cape and London; P. N. Kapur, Lahore and London; R. St. J. Kemm, Bristol; G. M. King, Cardiff and King's Coll.; J. G. Kingsbury, Guy's; C. K. Lakshmanan, Madras and St. Bart.'s; J. C. C. Langford, St. Bart.'s; Kathleen M. Lankester, Royal Free; G. A. Q. Lennane, Cambridge and St. Thomas's; H. M. O. Lester, St. Thomas's; Muriel A. Lester, Royal Free; T. J. Lloyd, Cardiff; A. McMillan, Birmingham; S. P. Meacock, Cardiff and Guy's; J. G. Milner, Cambridge and St. Bart.'s; V. S. Mitcheson, Cambridge and Birmingham; S. K. Montgomery, Univ. Coll.; A. J. Moody and C. A. Moody, St. Bart.'s; Florence I. R. Moore, Royal Free; W. G. R. Morris, Bristol; C. A. Mulligan, Manchester; Marjorie Murrell, Royal Free; W. Ogden, St. Bart.'s; J. B. Oldham, Liverpool; Dorothy M. Payton, Birmingham; A. P. Pearce, Leeds and London; C. O. Perera, Ceylon; A. Pierce, Birmingham; E. P. Pratt, Durham and St. George's; B. Press, St. Bart.'s; J. Rafalowsky, Zurich and Univ. Coll.; S. Randall, London; Grace D. Rice, St. Mary's; H. S. Rich, Sydney and Middlesex; G. D. Robb, Otago and Middlesex; J. E. C. Rouse, St. George's; A. T. F. Rowley, Bristol; T. A. Seekings, Univ. Coll.; R. Sellick, St. Thomas's; D. G. Shields and J. R. Smith, Cambridge and St. Bart.'s; J. S. Spickett, Cardiff and St. Bart.'s; A. A. Spiro, Manchester; E. F. Stead, London; G. H. Steele, Univ. Coll.; J. S. Symons, London; Catharine F. Taylor, Royal Free; G. Taylor, St. Mary's; Henrietta Trend, Royal Free; Joan W. Urwick, Charing Cross; K. H. Uttley, Cambridge and Univ. Coll.; J. M. van Schalkwyk, Cape and Guy's; Y. S. Wan, Cambridge and St. Bart.'s; E. C. Warner and R. L. Waterfield, Guy's; M. A. Weisman, Manchester; W. S. Whimster, Guy's; R. M. Windeyer, Cambridge and St. Bart.'s; K. K. Wood, Manchester; J. Wood, King's Coll.; H. M. Woodman, Cambridge and King's Coll.; and H. C. Wykerd, Cape and London.

Diplomas in Public Health were conferred, conjointly with the Royal College of Surgeons of England, upon the following candidates:—

J. V. Armstrong, A. Bajaj, Balmokand, E. M. Bergheim, E. R. W. Gilmore, Audrey M. Hughes, J. A. Kerr, J. H. M. Lloyd, Marian Lones, H. L. Oldershaw, Ethel B. Poole, G. Singh, L.-H. D. Thornton, J. G. Walker, and Moreen Whelton.

Diplomas in Tropical Medicine were also conferred upon the following candidates:—

Balmokand, J. N. Banks, A. Blair, J. H. Bowyer, H. H. Brown, E. N. Cook, A. C. Craighead, N. E. Goldsworthy, T. S. Goodwin, P. F. A. Grant, A. N. Haworth, L. H. Henderson, S. Khan, R. A. E. Klaber, K. Lumsden, J. R. Maleri, J. S. E. Manley, A. S. Mohammed, H. J. Moore, J. W. Scharff, E. B. Struthers, and J. L. Stuart.

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held recently the following candidates were successful in the undermentioned subjects:—

Surgery.—T. A. Lazaro, St. Bart.'s; I. H. Mackay, Sydney; K. E. R. Robertson, St. Mary's; F. Smith (Section I.), Manchester; and P. W. Tobin, St. Mary's.

Medicine.—E. H. Boodrie and F. Carroll, St. Mary's; T. G. L. Davies, St. George's; C. M. Moody and A. B. Osbourne, St. Mary's; and J. Wilson, Leeds.

Forensic Medicine.—F. Carroll, St. Mary's; P. H. Knowles, Bristol; C. H. Mason and A. B. Osbourne, St. Mary's; and O. W. Percival, Sydney and London.

Midwifery.—R. V. Cookes, B. Horwitz, and T. McD. Kellough, Guy's; P. H. Knowles, Bristol; C. S. Netscher, St. Mary's; W. Irving Pierce, Boston, U.S.A.; S. R. G. Pimm, Guy's; G. E. Rowan, St. Thomas's; B. L. Steele, Univ. Coll.; R. F. Stubbs, Manchester; P. W. Tobin, St. Mary's; and D. Winstanley, Liverpool.

The Diploma of the Society was granted to the following candidates entitling them to practise medicine, surgery, and midwifery: E. H. Boodrie, T. McD. Kellough, C. M. Moody, B. L. Steele, R. F. Stubbs, and J. Wilson.

Dr. J. D. C. White has been appointed Chairman of the Harrow Urban District Council.

University of London, University College.—Prof. Elliot Smith will deliver a lecture on the Taungs Skull: Missing Links, at University College, London, on Friday, May 22nd, at 5.30 p.m. The lecture will be illustrated by casts and lantern slides of various "missing links." The proceeds from the sale of tickets will be devoted to the St. Christopher's Working Boys' Club, 39, Fitzroy-square, W., which is largely maintained and organised by the students and staff of University College. A leaflet giving full particulars of the lecture and price of tickets can be obtained by sending a stamped addressed envelope to Miss Husbands, University College, Gower-street, London, W.C. 1.

Sierra Leone: Sir Alfred Lewis Jones Tropical Research Laboratory.—In the course of his visit to West Africa, H.R.H. the Prince of Wales, on April 7th, inspected this laboratory, which is a branch of the Liverpool School of Tropical Medicine, and was built after the war out of funds bequeathed by the founder of the School, Sir Alfred Jones. The Prince was received by the director, Prof. B. Blacklock, with Mrs. Blacklock, Dr. Gordon, assistant director, and Dr. Macdonald, research assistant, and showed great interest in work that is being done by the laboratory in the investigation of tropical diseases.

Royal Institution.—The annual meeting of the members was held on May 1st, Sir James Crichton-Browne, treasurer and vice-president, in the chair. The annual report of the Committee of Visitors for the year 1924, testifying to the continued prosperity and efficient management of the institution, was read and adopted. Seventy-eight new members were elected in 1924, and 63 lectures and 19 evening discourses were delivered. The books and pamphlets presented amounted to about 273 volumes, making with 678 volumes (including periodicals bound) purchased by the managers, a total of 951 volumes added to the library in the year. The following were unanimously elected as officers for the ensuing year: President: The Duke of Northumberland; Treasurer: Sir James Crichton-Browne; Secretary: Sir Arthur Keith; Managers: Sir Thomas Barlow, Sir John Biles, Sidney G. Brown, Ernest Clarke, Sir Dugald Clerk, Prof. J. A. Fleming, Earl Iveagh, Sir George Lawson Johnston, Sir Oliver Lodge, Charles H. Merz, Sir Ernest Moon, the Hon. Sir Charles Parsons, Sir Edward Pollock, Sir Robert Robertson, and Sir Almroth Wright; Visitors: K. A. Wolfe Barry, Alfred Carpmael, Edward Dent, William H. Eccles, Viscount Falmouth, Frederick H. Glew, W. E. Lawson Johnston, Alexander G. Low, Ronald Malcolm, Clifford C. Paterson, Sir Walter Peacock, Herbert M. Phipson, Hugh Munro Ross, Frank Coston Taylor, and John Tennant.

Fellowship of Medicine and Post-Graduate Medical Association.—On Tuesday, May 12th, at 5.30 p.m., Mr. J. P. Lockhart-Mummery will lecture for the Fellowship of Medicine in the West Lecture Hall (1, Wimpole-street) on the Diagnosis and Treatment of Internal Piles.—From May 18th to May 29th, Saturday excepted, the London Temperance Hospital will hold a course for the convenience of those in general practice. A clinical demonstration illustrated by cases will be given at 4.30 p.m., lasting for one hour, followed by a short lecture at 5.30 p.m.—The month's course in Psychological Medicine at the Maudsley Hospital began on May 4th, and the demonstrations and lectures embrace all aspects of this particular subject.—The Central London Throat, Nose, and Ear Hospital will begin a three weeks' special course from May 11th to May 30th, consisting of clinical demonstrations with out-patient clinics and ward rounds dealing with cases peculiar to this hospital. An operative surgery class will also be arranged.—From May 18th to the end of the month will be given a special course in Diseases of Infants at the Infants Hospital, consisting of lectures, out-patients' clinics, "round table" consultations, and visits to four different centres away from the hospital.—There will also be a two weeks' course in Dermatology from May 18th at the Hospital for Diseases of the Skin, Blackfriars. Instruction will be given in the out-patient department from 2.30 p.m., with a special demonstration on selected cases on May 19th, together with venereal cliniques twice weekly.—The following courses will take place in June on Diseases of the Chest at the Victoria Park Hospital for Diseases of the Heart and Lungs: Gynæcology at the Chelsea Hospital for Women; Tropical Medicine at the London School of Hygiene and Tropical Medicine; Venereal Disease at the London Lock Hospital; and an intensive course at the London Temperance Hospital and associated hospitals.—Copies of each syllabus of the foregoing courses, together with the programme of work of the Fellowship of Medicine, may be obtained from the Secretary at 1, Wimpole-street, London, W. 1.

Manx Hospital Extension.—The Manx legislature have granted the Douglas Corporation permission to borrow £15,000 to build a new wing to the Mental Hospital.

Honour for Manchester Surgeon.—Dr. A. G. C. Magian, of Manchester, has received the Palmes d'Officier de l'Instruction Publique for his work in connexion with the Manchester French Hospital and the Entente League.

Medico-Psychological Association.—A quarterly meeting of the Medico-Psychological Association of Great Britain and Ireland will take place on Thursday, May 21st, at 11, Chandos-street, Cavendish-square, London, W., under the presidency of Dr. M. J. Nolan, at 2.30 p.m., when the Maudsley lecture, entitled "Mind and Brain," will be given by Dr. J. Shaw Bolton.

Queen's University (Belfast) Club, London.—The third annual dinner of this club will be held in the Connaught Rooms, Great Queen-street, London, W.C., on Thursday, May 21st, at 7.30 for 8 o'clock. Chairman, Major-General Sir Havelock Charles. Members who intend to be present or to introduce guests are requested to give notice to the hon. secretaries, 17, Wimpole-street, W. 1, not later than Monday, May 18th. The charge will be 12*s.* 6*d.* (exclusive of wines).

Medical Practice in Russia.—The Narkowsdrav (People's Commissariat of Public Health) states that doctors of medicine who have studied abroad and have obtained their diplomas abroad must pass a medical examination at one of the Russian universities in order to be entitled to practise medicine in U.S.S.R. Applications must be sent in to the Narkowsdrav.

Canadian Honour to a Medical Man.—Convocation of McGill University, Montreal, resolved on May 19th to confer the degree of LL.D. on, amongst others, Dr. David McKay Cassidy, medical superintendent of the County Asylum, Lancaster. Dr. Cassidy graduated M.D. and C.M. at McGill in 1866, became L.R.C.S. Edin. in 1867 and F.R.C.S. in 1875, B.Sc. Edin. in 1882 and D.Sc. in Public Health in 1884.

The late Dr. William Wallers.—William Wallers, M.R.C.S. Eng., one of the oldest and one of the busiest practitioners in Blackburn, died on April 29th in his sixty-eighth year. A student in the late seventies at what was then the Royal School of Medicine, Manchester—later Owens College Medical School—he qualified M.R.C.S. in 1881, became an assistant house surgeon at Stockport Infirmary, a house surgeon at Manchester Royal Infirmary, and then for three years house surgeon at the Blackburn and East Lancashire Infirmary. Thereafter, 40 years ago he settled in Blackburn, where he was in active practice until overtaken by a severe illness some months back.

Royal Commission on National Health Insurance.—The twenty-sixth meeting of this Commission was held at the Home Office, Whitehall, on April 30th, Sir Andrew Duncan in the chair. Evidence was given on behalf of the British Medical Association by Dr. R. A. Bolam, chairman of the Council, Dr. H. B. Brackenbury, chairman of the Representative Body, Dr. H. Guy Dain, chairman of the Insurance Acts Committee, Dr. Alfred Cox, medical secretary, and Dr. H. J. Cardale, chairman of the London Panel Committee. The following subjects were dealt with: The quality of the medical service given under the panel system, the conditions to be satisfied by a public service under the Health Insurance Scheme, the range of persons to be included within the scheme, extension of scope of medical service, coördination of existing services, the arguments against a salaried medical service.

Manchester Hospital Saturday Fund.—At the eighteenth annual meeting held in Manchester on April 24th it was stated that greater progress had been made during the last year than in the preceding one. The weekly contributions from workpeople amounted to £22,442, as compared with £18,377 in 1923, a matter of congratulation, as trade was still far from normal. The Workpeoples' Convalescent Homes were established in 1907 and from that time to the end of last year the admissions of men and women numbered 20,578. Regular contributors of one penny a week were entitled to a fortnight's stay at the homes to re-establish their health after illness or accident. During the last two years the contributions to the Saturday Fund have increased by almost 100 per cent. Of the £22,000 contributed in pennies £11,841 would be given to the hospitals, as against £9401 in 1923 and £5500 in 1922. Since 1907 the total contributed to the hospitals was £98,000. Out of every penny subscribed more than a halfpenny went to the hospitals, and the balance to the Convalescent Homes Fund. Out of every £1000 the sum of £850 went to the hospitals and £150 to the Convalescent Homes Fund.

Sir Humphry Rolleston, Regius Professor of Physic at the University of Cambridge, has been elected to a Fellowship at St. John's College, Cambridge.

Hove Hospital.—A public meeting on May 1st, presided over by the mayor (Alderman W. Jago), passed a resolution of thanks to Mr. Bernhard Baron for his generous offer to build and furnish at a cost of £7000 a new wing to this institution; and another resolution appealing to the townspeople to provide the necessary funds for the maintenance of the enlarged building.

Chadwick Public Lectures.—Two lectures, illustrated with epidiascope and lantern slides, will be given by Prof. Emile Brumpt, of the University of Paris, at 5.15 P.M., on May 25th and 29th. The first lecture on How to Conduct an Anti-Malarial Campaign will be delivered in the Barnes Hall, Royal Society of Medicine, 1, Wimpole-street, London, W., Sir William Collins presiding, and will be preceded (at 5 P.M.) by the presentation of the Chadwick gold medal and Royal Air Force prize of £100 to Wing-Commander Harold E. Whittingham, M.B. This award is made upon the nomination of Air-Commodore David Munro, Director of Medical Services, Royal Air Force, who will be present. The second lecture, entitled the Prophylaxis of Sleeping Sickness, will be delivered in the Lecture Room, Royal Society of Arts, John-street, Adelphi, London, W.C., Sir James Crichton-Browne, F.R.S., presiding.

Royal Commission on Lunacy: Evidence of the Medico-Psychological Association.—At the sitting of the Commission on May 4th, a memorandum was submitted by the Medico-Psychological Association of Great Britain and Ireland embodying the views of the Association and containing the following recommendations:—

That "clinics for mental disorders," preferably in connexion with the universities, medical schools, and general hospitals, should be established.

That the reception into mental institutions of patients, whether of the private (hereinafterwards called "paying patients") or of the pauper (hereinafterwards called "rate-aided patients") class, should follow a similar procedure.

That a considerable proportion of admissions to mental institutions should be dealt with on a voluntary basis, so that such voluntary treatment should be extended to the rate-aided class, for which legislative sanction has already established precedents at the Maudsley Hospital and at the City of London Mental Hospital.

That special legal machinery should be devised for treating early non-volitional cases.

That a "provisional order" should be instituted as an intermediary measure before the usual "judicial order" for detention is enforced.

That when such detention is necessary for the cure or care of patients, medical certification should take place as constituting evidence, but that the authority for detention, discharge, and continuation, i.e., renewal, of orders should entail the responsibility of some authorised person not acting in a medical capacity.

That a broader conception should be taken of the functions of both the central and local authorities for "lunacy" or mental health administration.

That the Poor Law authorities should be superseded by the local authorities in regard to the care, treatment, and maintenance of necessitous patients suffering from mental disorders.

The Chairman of the Commission, Mr. H. P. Macmillan, said that they were convinced of the desirability of establishing mental clinics associated with, but separated from, the general hospital, and of treating patients at these clinics without certification. The immediate difficulty was to evolve machinery to carry out this recommendation. An interesting discussion followed on the possibility of voluntary detention.

Royal Medical Benevolent Fund.—At the last meeting of the Committee 32 cases were considered and £476 voted to 30 applicants. The following is a summary of some of the cases relieved:—

Widow, aged 72, of L.R.C.P. Edin. who practised in the Isle of Man and died in 1912. Applicant has supported herself, and her daughter up to the time of her marriage, by taking posts as housekeeper. She has just had to give up her last post owing to sudden collapse due to influenza and double pneumonia. Friends have managed to keep her in a nursing home, but the applicant is now back again in her modest lodging and not fully recovered her strength. Her only income is a life interest bringing her in £30 per annum and the post given up was at the rate of £50 per annum. Rent 13*s.* 6*d.* a week. Voted £18 in 12 monthly instalments.

Widow, aged 62, of L.S.A. who practised in Cambridgeshire and died in 1923. Applicant has taken a house so as to be able to let rooms and provide for herself and two daughters living at home. Applicant's total income is the rent from a house amounting to £55 per annum, and a daughter, who is a nursery governess, pays the applicant 10*s.* a week. Rates £20 per annum. Applicant asks for a grant towards 50 guineas per annum for a son, who has been in an institution for mental defectives for seven years. Voted £20 in two instalments.

Widow, aged 47, of M.B. Camb. who practised in Worcestershire and died in 1922. Applicant is left with five children, ages 9 to 17. The three eldest are at boarding school and provided for by friends; the two youngest are with applicant having lessons at home. Applicant lives in her own house and the rates amount to £20 per annum. She has an income of £250 per annum, an allowance from the grandmother of £100. Applicant asks the Fund to help her with votes for Epsom for her youngest boy Geoffrey, aged 9. Committee promised to help in getting votes for the youngest son.

L.R.C.P. & S.I., 1879, aged 74, who practised in London. He gave up practising owing to his wife's ill-health and travelled abroad on his wife's account. She died in 1899. Since then applicant has taken locums and during the war was on sea transport. Received £52 10*s.* from locums during the last 12 months. Room, breakfast, and supper amounts to £1 a week. Owing to influenza and phlebitis has not been able to pay his landlady, to whom he owes £28. Voted £30.

Wife, aged 40, of L.R.C.P. & S. Edin. who is now in a sanatorium at 4 guineas a week, which is paid by his brother. Applicant wishes to take a house so that her husband can have the benefit of good air after he leaves the sanatorium in a month's time. Local medical practitioners paid the applicant £3 while carrying on her husband's practice. She received £46 from a whist drive, and the only money in hand is £100, which the applicant wishes to reserve towards the house mentioned above. The two eldest children are at the National Children's Home and Orphanage, the two youngest, aged 3½ and 1 year, are with the applicant. Voted £10.

Daughter, aged 56, of M.R.C.S. Eng. who practised in Middlesex and died in 1914. Applicant has rheumatoid arthritis and is in general ill-health. She has not had any special training for business or a profession and is only able to do plain needlework, which brought her in £12. She has £14 per annum from war loan and £5 from the National Benevolent Institution. Rent 3*s.* a week. Our local secretary for Devon says: "With some money a better room could be got for her than the miserable one she now occupies." Voted £26 in 12 monthly instalments.

Widow, aged 49, of L.R.C.P. Edin. who practised in Lancashire and died in October, 1924. Applicant is left with three children, ages 19, 12, 10, and only £40 per annum from some railway shares. Rent £1 a week for two rooms. The eldest son is a farm pupil and only receives pocket money; the other children are at school. Applicant wishes to sell out her capital and start a business and asks the Fund to help her with the education of her two youngest children until she is established. Voted small grant and referred to the Guild.

Subscriptions may be sent to the Hon. Treasurer, Sir Charters Symonds, at 11, Chandos-street, Cavendish-square, London, W. 1.

Parliamentary Intelligence.

HOUSE OF COMMONS.

Wednesday, April 29th.

Dried Milk and Infantile Death-rate.

Mr. **Groves** asked the Minister of Health whether his attention had been called to the continued reduction in the infantile death-rate within the county borough of West Ham; whether he was aware that these reductions were side by side with the increased supply of dried milk and the general development of the health services of the borough; and whether his department proposed to make any recommendation to the local authorities of the country respecting the use of dried milk in preference to liquid milk.—Sir **Kingsley Wood** replied: The answer to the first part of the question is in the affirmative. As regards the second part, I may point out that the reduction in recent years in the infantile death-rate in West Ham is comparable with the reduction which has occurred in other similar areas, and my right hon. friend is advised that it cannot be attributed exclusively to any particular measures which have been adopted in this area. The answer to the third part is in the negative. The question of the supply of dried or liquid milk is a matter primarily for the decision of the local authorities, regard being paid to all the relevant circumstances of their districts.

Thursday, April 30th.

Bengal Criminal Law Amendment Act.

Mr. **Thurtle** asked the Under Secretary of State for India whether it was the intention of the Government now to repeal Bengal Regulation III. of 1818, in view of the fact that the Bengal Criminal Law Amendment Act, 1925, was now part of the criminal law of India.—Earl **Winterton** said: The reply is in the negative.

Government and Opium Agreements.

Sir **Walter de Frece** asked the Prime Minister whether it was the intention of Great Britain to ratify the protocol reached at the recent Opium Conference at Geneva; and whether he proposed to lay the document before Parliament.—Sir W. **Joynson-Hicks** replied: As has been stated in reply to a previous question by Lady Astor on March 24th, it is the intention of the Government as at present advised to ratify the agreements reached at the recent conferences. I doubt whether it is necessary to incur the expense of printing the documents as a Parliamentary paper at this stage, as they will doubtless be published very shortly by the League of Nations office.

Mr. **FORREST** asked the Prime Minister whether, in view of the fact that the central board to be established under the last Anti-Opium Conference at Geneva was not likely to come into operation for some time, he would state whether the advisory committee on opium traffic was still in existence; whether it would hold its annual meeting this year, and, if so, when; and what was to be the policy of the British Government in respect of it.—Mr. **LOCKER-LAMPSON** replied: The advisory committee whose function is to assist and advise the Council of the League in dealing with any question that may arise in connexion with the League's supervision of the drug traffic, and to promote the fullest possible international coöperation in regard to the matter, is still in existence and will, so far as I am aware, continue to exist. I understand a meeting of the committee will be held as usual this year, some time before the meeting of the assembly in September, but the Government has not yet been informed of the date. I am not in a position to make any statement of policy, as the agenda for the meeting has not yet been settled.

Supply of Insulin by Poor-law Authorities.

Colonel **DAY** asked the Minister of Health if, in view of the reduction in the price of insulin, he could now say whether it was supplied free by all Poor-law authorities on the recommendation of their medical officers.—Mr. N. **CHAMBERLAIN** replied: I have no reason to suppose that Poor-law authorities are not supplying insulin in all proper cases in which application is made to them and supported by their medical officers.

Royal Commission on National Insurance.

Mr. **OAKLEY** asked the Minister of Health, in connexion with the Royal Commission on National Health Insurance, if he could give an approximate date when the report of the Commission would be presented to Parliament.—Mr. **LOCKER-LAMPSON** (Under Secretary for the Home Office) replied: I understand that satisfactory progress is being made with the hearing of evidence by the Royal Commission on National Health Insurance, but I am not in a position to say when their report may be expected.

Education of Defective Children.

Mr. **HARRIS** asked the President of the Board of Education if he would state the number of urban and rural local education authorities in which no provision existed for the education of defective children.—Lord E. **PERCY** replied: No certified special schools for defective children of any type exist in the areas of 27 county authorities and 102 non-county authorities. I would, however, remind the hon. Member that the majority of local authorities in whose areas no special schools exist make arrangements for the attendance of defective children at special schools in other areas.

Delays in Medical Board Decisions.

Captain **BOWYER** asked the Minister of Pensions whether he was aware that in some cases there was undue delay in notifying results of medical boards; and would he take steps to remedy this.—Major G. C. **TRYON** replied: Under the instructions of the Ministry the decision upon a case following a medical examination is conveyed to the claimant as promptly as possible. In a very few cases, as my hon. and gallant friend will understand, expert opinion or additional evidence may have to be obtained, and some unavoidable delay may occur. I have, however, recently taken active steps to secure that the speediest decision possible is arrived at on all outstanding cases.

MONDAY, MAY 4TH.

Post-mortems in Criminal Cases.

Mr. A. R. **KENNEDY** asked the Home Secretary whether he was aware of the disadvantage which might attach to a person accused of murder, or manslaughter, in the conduct of his defence arising from the practice of appointing one medical man only to conduct a post-mortem examination; and whether he would take the necessary steps to ensure that, where a person had died in circumstances which might lead to a criminal charge being made against another in connexion with the death and a post-mortem examination was held, a duly qualified medical practitioner should be appointed to watch the examination in the interests of the person, if any, thereafter to be charged.—Mr. **LOCKER-LAMPSON** replied: My right hon. friend does not see his way to propose legislation for this purpose. A post-mortem examination is not a matter of advocacy, but of scientific investigation. The Director of Public Prosecutions is, however, considering whether it may not be possible to arrange that the defence shall have the opportunity of appointing a medical man to be present on behalf of the defendant when the post-mortem examination is performed.

The Lee Commission Report.

Mr. **LANSBURY** asked the Under Secretary of State for India whether the Government had given instructions that the terms of the recommendations of the Lee Commission Report were to be extended to European members of the superior central services recruited in India and who had an Asiatic domicile.—Earl **WINTERTON** replied: I would refer the hon. Member to Statutory Rules and Orders No. 1395 of 1924. The pay and passage recommendations of the Lee Commission Report have been extended to members of the 15 central services which it has been decided to regard as superior in precisely the same way as they have been given to members of the All India Services (other than the Indian Civil Service); that is to say, eligibility for these concessions depends upon an officer having a non-Asiatic domicile. The pension concessions have also been given to the 13 of these 15 services which are pensionable on a rupee basis and for these an officer of Asiatic domicile is eligible.

TUESDAY, MAY 5TH.

Maternity and Child Welfare Services.

Mr. **LANSBURY** asked the Minister of Health the amount of public money spent by local authorities during the years ending March, 1913, and March, 1925, on child welfare clinics and other centres, and the amount spent on the supply of milk to nursing and expectant mothers during the same period, showing the amount raised from the rates and the amount paid from the national Exchequer.—Sir **KINGSLEY WOOD** replied: No figures are available as regards maternity and child welfare services in respect of the year ended March, 1913, the year ended March 31st, 1915, being the first year in respect of which Exchequer grant was paid on these services. The total net expenditure of local authorities in England and Wales on all maternity and child welfare services in that year was (approximately) £66,700, and of voluntary agencies receiving Exchequer grant (approximately) £16,200. No separate figures as to the expenditure of local authorities on maternity and child welfare centres and clinics, or on the supply of milk to nursing and expectant mothers and children, are available prior to the year ended March, 1920. For that year the net expenditure was as follows: Maternity and child welfare centres and clinics, £132,379 (exclusive of the cost of medical supervision and services of health visitors, which cannot be given separately in respect of this item). Supply of milk and food to nursing and expectant mothers and children, £163,648. The net expenditure on centres and clinics provided by voluntary agencies receiving Exchequer grant in that year was approximately £102,000. Particulars of the actual expenditure on these services for the year ended March, 1925, are not yet available, but the net expenditure for the year ended March, 1924, was as follows: Maternity and child welfare centres and clinics, £134,340 (exclusive of medical supervision and health visitors' services). Supply of milk and food to nursing and expectant mothers and children, £200,100. Centres and clinics provided by voluntary agencies receiving Exchequer grant (approximately), £105,100. One half of the expenditure referred to above was met by way of Exchequer grant, and one-half of the net expenditure of local authorities was met out of the rates.

Recent Increase in Small-pox Cases.

Sir **WILLIAM DAVISON** asked the Minister of Health whether his attention had been called to the recent increase in cases of small-pox throughout the country; what was the total number of cases which had been notified during the past three months; and whether he had received any report as to the causes which had brought about the recent increase in such cases.—Sir **KINGSLEY WOOD** (Parliamentary Secretary to the Ministry of Health) replied: The answer to the first part of the question is in the affirmative. The total number of cases of small-pox notified in England and Wales during the 12 weeks from Jan. 4th to March 28th was 1609. My right hon. friend has received numerous reports made by medical officers of his department who have visited the districts in which small-pox is prevalent, and is advised that the recent increase in the number of cases may be attributed to the neglect of vaccination in many of the invaded districts, and to neglect of the precautions which are essential if the spread of the disease is to be checked. My right hon. friend may perhaps take this opportunity of informing the House and the country that he is advised that there is no doubt that the disease now so prevalent in certain districts is true small-pox, though happily mild in degree, and that vaccination is the only reliable protection against it.

Sir W. **DAVISON**: Is it a fact that the late Minister of Health made an Order making it easier for people to obtain exemption from vaccination?

Dr. **WATTS** asked if the hon. gentleman was aware that each of these cases cost the local authority £250 for treatment, isolation, disinfection, and so forth, and if his attention had been drawn to the report of a medical officer of health which proved distinctly that in his area the money they had to spend on these cases could have built 1000 or 1500 houses ?

Mr. N. MACLEAN asked if the Government would issue orders to the local authorities to extend the building of houses and the clearing of sites, and to take steps to eliminate this disease by means of fresh air and pure food, and not by vaccination ?

No answers were given.

Sir VICTOR WARRENDER asked the Minister of Health if his attention had been drawn to the increase of small-pox in certain areas ; and whether the incidence of the disease had been increased since the coming into effect of the present regulations affecting exemption from vaccination.—Sir KINGSLEY WOOD replied : The answer to the first part of the question is in the affirmative. As regards the second part, it is presumed that my hon. friend is referring to the Order issued by the late Minister of Health which had the effect of reversing an Order issued by my right hon. friend on July 20th, 1923, and of reinserting the form of statutory declaration of conscientious objection in the notice of the requirement of vaccination handed to the parent or guardian when the birth of a child is registered. The Order of the late Minister came into force on Oct. 1st last, and my right hon. friend is carefully watching its effect, but there is not yet sufficient evidence to enable him to form a final opinion.

Dr. WATTS : How does the hon. gentleman explain the fact that, despite the number of cases of small-pox, proceedings are rarely, if ever, instituted under the present Vaccination Act ?

Sir KINGSLEY WOOD asked for notice of the question.

Lieut.-Colonel FREMANTLE : Are the Government considering the transference of these powers from the boards of guardians to the sanitary authorities, so that they may be worked out in common with the general upkeep of the public health ?

No reply was given.

School Children and Infectious Disease.

Colonel DAY asked the Minister of Health if he would consider the introduction of legislation to prevent persons in control of children, as, for example, headmasters and managers of schools, from permitting them when in an infectious condition to enter public vehicles or go into public places at the risk of spreading infection.—Sir KINGSLEY WOOD replied : Provision is already made in Section 126 of the Public Health Act, 1875, for preventing the exposure, without proper precautions, in public places and public conveyances of children suffering from any dangerous infectious disorder. Similar provisions as regards London are contained in Sections 68 and 70 of the Public Health (London) Act, 1891, and there are numerous supplementary provisions on this subject contained in local Acts. The question of introducing further legislation dealing generally with the matter will be considered in connexion with the proposed amendment of the Public Health Acts.

DONATIONS AND BEQUESTS.—By the will of the late Mr. Thomas Hamer, J.P., of The Banks, Upper George-street, Tyldesley, Lancs, the testator left, among other bequests, £1000 to the Manchester Royal Infirmary ; £500 each to the Manchester Royal Eye Hospital, Henshaw's Blind Asylum, Manchester, the Southport Convalescent Hospital, the Leigh Infirmary, the Wigan Infirmary, the Bolton Infirmary, the Devonshire Hospital, Buxton, Derbyshire, Dr. Barnardo's Homes, and the National Society for the Prevention of Cruelty to Children ; and £250 each to the Royal Society for the Prevention of Cruelty to Animals, the Royal Manchester Children's Hospital, Pendlebury, and the Manchester and Salford Deaf and Dumb Benevolent Association.—Mrs. Mary Eliza Culme-Seymour, of Knightsbridge, S.W., bequeathed £1000 to the Westminster Hospital for a bed to be called the "Robert George Clutton" bed.—Mr. James David Williams, of Styal, Cheshire, a Manchester merchant and shipper, left 100 fully-paid preference shares in the Manchester Ship Canal Company each to the Manchester Royal Infirmary, the Ancoats Hospital and Ardwick and Ancoats Dispensary to endow a J. D. Williams bed, the St. Mary's Hospitals, Manchester, to endow a J. D. Williams bed ; 50 such shares to the Crippled Children's Home, Marple, for a J. D. Williams cot ; and 50 such shares to Manchester and Salford Boys' and Girls' Refuges and Homes and Children's Aid Society.—The Salford Royal Hospital has received a grant of £1500 and the Salford District Nurses' Home £400 and other hospitals £1310 from the Booth Charities.—Of the total annual receipts of the Samaritan Hospital for Women—viz., £2932—the patients themselves contributed £864.—The Christie Hospital, Manchester, has received £2500 from the executors of the late Mr. Edwin Kershaw, of Bolton.

MEETINGS OF SECTIONS.

Wednesday, May 13th.

SUBSECTION OF PROCTOLOGY (Section of Surgery) : at 5 P.M.
Annual General Meeting :
Election of Officers and Council.
Discussion on
The Value or Otherwise of X Rays in the Diagnosis of Diseases of the Colon.
Openers :
Dr. Gilbert Scott and Mr. Hamilton Drummond.
Other Speakers :
Dr. W. H. Coldwell, Sir Charles Gordon-Watson, Dr. Arthur Hurst, Mr. J. P. Lockhart-Mummery, Dr. Bertram Shires, Dr. Ulysses Williams, and others.
Annual Dinner :
The Annual Dinner will be held at Oddenino's Restaurant, 60, Regent-street, W., at 8.15 for 8.30 P.M. Price 12*s.* 6*d.*

Thursday, May 14th.

NEUROLOGY : at 5 P.M.
Annual General Meeting :
Election of Officers and Council.
At this meeting pathological specimens illustrating diseases of the nervous system will be shown, and those who wish to show specimens should communicate with the Hon. Secretaries at an early date so that accommodation may be made for their exhibits.
Dinner :
The Meeting will be followed by a Dinner at 7.45 P.M. at the Langham Hotel. Price 12*s.* 6*d.*

PSYCHIATRY : at 5.30 P.M.
Annual General Meeting :
Election of Officers and Council.
N.B.—Please note change of date and time.

TROPICAL DISEASES AND PARASITOLOGY : at 5.30 P.M.
Annual General Meeting :
(1) Election of Officers and Council.
(2) Other Sectional business.
N.B.—No papers will be read and no demonstrations will be given.

Friday, May 15th.

ELECTRO-THERAPEUTICS : at 5 P.M.
Annual General Meeting :
Election of Officers and Council.
The Discussion on High Voltage and Radio-Therapy, adjourned from the March Meeting, will then take place, in which Dr. Finzi and others will take part.
Annual Dinner :
The Annual Dinner will be held the same evening at the Langham Hotel, at 7.30 for 7.45 P.M. Price 10*s.* 6*d.*

ROYAL INSTITUTION, 21, Albemarle-street, W.
MONDAY, May 11th.—5.15 P.M., Prof. J. Barcroft : Effects of Climate on the Circulation (IV.).
FRIDAY.—9 P.M., Prof. C. G. Darwin : Recent Developments in Magnetism.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.
MONDAY, May 11th.—8 P.M., Annual General Meeting. 9 P.M., Sir William Hale-White : Annual Oration. The Medical Career of John Keats. To be followed by a Conversazione.

HARVEIAN SOCIETY OF LONDON.
THURSDAY, May 14th.—4 P.M. (at the Paddington Infirmary, 285, Harrow-road, W.), Clinical Meeting.

BIOCHEMICAL SOCIETY.

Monday, May 11th.—(At the Middlesex Hospital, W.). 5 P.M. *Communications:* S. L. Baker: Intrarenal Obstruction Caused by the Products of Hæmolysis. R. W. Scarff: Experimental Atheroma in Rabbits Produced by Cholesterol Feeding. O. Rosenheim and J. C. Drummond: A Delicate Colour Reaction for the Presence of Vitamin A. E. H. Lepper and C. J. Martin: The Influence of Salt Concentrations on the C_H of Buffer Solutions as indicated by the Electrometric and Colorimetric Methods Respectively. H. W. Kinnersley and R. A. Peters: Anti-neuritic Yeast Concentrates. L. Gross and P. Eggleton: A Note on Blood-Sugar Levels in Rats Fed on Complete Diets and Diets Deficient in Vitamin B. T. A. Henry, T. M. Sharp, and H. C. Brown: Bactericidal Action of Some Organic Compounds of Mercury. F. Dickens, E. C. Dodds, and S. Wright: Observations upon the Preparation, Properties, and Standardisation of the Ovarian Hormone.

LECTURES, ADDRESSES, DEMONSTRATIONS. &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

Monday, May 11th, to Saturday, May 16th.—West Lecture Hall, 1, Wimpole-street. Lecture arranged by the Fellowship of Medicine and open to all members of the medical profession. At 5.30 P.M., Mr. J. P. Lockhart-Mummery: The Diagnosis and Treatment of Internal Piles.—Central London Throat, Nose, and Ear Hospital, Gray's Inn-road, W.C. Special Course in Laryngology, Rhinology, and Otology. Clinical Course daily, morning and afternoon sessions. Operative Surgery Class every morning. These Courses may be taken separately, or combined.—Maudsley Hospital, Denmark-hill, S.E. Course in Psychological Medicine. Lectures on the Psychoneuroses, the Practical Aspect of Mental Deficiency, the Pathology of Mental Diseases, and Demonstrations in Clinical Psychiatry and Clinical Neurology.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

Monday, May 11th.—12 noon, Mr. Simmonds: Applied Anatomy. 2 P.M., Mr. Addison: Surgical Wards. 4.15 P.M., Staff Consultation on Cases of Interest.

Tuesday.—11 A.M., Mr. Endean: Venereal Diseases. 12 noon, Dr. Burrell: Chest Cases. 3 P.M., Dr. Pritchard: Medical Wards.

Wednesday.—11 A.M., Medical Registrar: Medical Wards. 2 P.M., Dr. Burnford: Medical Wards. 2.30 P.M., Mr. Donald Armour: Surgical Wards.

Thursday.—10 A.M., Dr. Grainger Stewart: Neurological Dept. 2 P.M., Mr. MacDonald: Genito-Urinary Dept. 4.15 P.M., Sir Henry Simson: Lecture: Meddlesome Midwifery.

Friday.—10.30 A.M. Dr. Dowling: Skin Dept. 12 noon, Surgical Registrar: Surgical Pathology. 2 P.M., Mr. Vlasto: Throat, Nose, and Ear Dept.

Saturday.—10 A.M., Dr. Saunders: Medical Diseases of Children. 10 A.M., Mr. Banks-Davis: Operations on Throat, Nose, and Ear.

Daily, 10 A.M. to 6 P.M., Saturdays, 10 A.M. to 1 P.M., In-patients, Out-patients, Operations, Special Departments.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C.1.

POST-GRADUATE COURSE: May–June, 1925.

Clinical Lectures and Demonstrations.

Monday, May 11th.—2 P.M., Out-patient Clinic: Dr. Hinds Howell. 3.30 P.M., Syphilis of Nervous System: Dr. Adie.

Tuesday, May 12th.—2 P.M., Out-patient Clinic: Dr. Walshe. 3.30 P.M., Subacute Combined Degeneration and Allied Diseases: Dr. Birley.

Thursday, May 14th.—2 P.M., Out-patient Clinic: Dr. Kinnier Wilson. 3.30 P.M., Methods of Testing the Eighth Nerve: Mr. Theodore Just.

Friday, May 15th.—2 P.M., Out-patient Clinic: Dr. Gordon Holmes. 3.30 P.M., Demonstration of Re-educational Methods in Exercise Room: Mr. Elmquist

Course of Lectures and Demonstrations on the Pathology of the Nervous System.

Monday, May 11th.—12 noon, The Cerebro-Spinal Fluid. Physiology and Pathology: Dr. J. G. Greenfield.

Course of Lectures and Demonstrations on the Anatomy and Physiology of the Nervous System.

Monday, May 12th.—12 noon, The Neuron, Conduction of the Nervous Impulse, The Reflex: Dr. Walshe.

Dr. H. J. Macbride will give a Course of Eight Clinical Demonstrations, chiefly on Methods of Examination of the Nervous System, in the Wards at 10 A.M. on Tuesdays and Fridays, if sufficient entries are received. The fee for this Course will be £2 2s. (commencing Tuesday, May 19th).

Mr. Armour and Mr. Sargent operate at the Hospital on Tuesday and Friday mornings at 9 A.M., or at such other times as may be announced.

Any part of the Course may be taken separately. Special arrangements will be made for those unable to take the whole Course.

Fees should be paid to the Secretary of the Hospital at the Office on entering for the Course.

J. G. Greenfield, Dean of Medical School.

UNIVERSITY OF LONDON ADVANCED LECTURE IN NEUROLOGY.

Friday, May 15th.—5 P.M. (at Charing Cross Hospital Medical School), Prof. B. Brouwer (Amsterdam): The Projection of the Retina in the Brain.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.

Thursday, May 14th.—4 P.M., Mr. Barrington-Ward: Glands in the Neck.

INSTITUTE OF PATHOLOGY AND RESEARCH, ST. MARY'S HOSPITAL.

Thursday, May 14th.—5 P.M., Mr. A. T. Glenny: The Principles of Immunity as Illustrated by Protective Inoculation against Diphtheria.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, Leicester-square, W.C.

Tuesday, May 12th.—5 P.M., Dr. Barber: Scleroderma.

Thursday.—5 P.M., Dr. MacLeod: Tuberculosis Cutis.

UNIVERSITY OF LIVERPOOL POST-GRADUATE LECTURES. (At 3.30 P.M.)

Tuesday, May 12th.—(At the Southern Hospital.) Mr. T. L. de Courcy: Treatment of Common Eye Disorders.

Wednesday.—(At the Northern Hospital.) Mr. Simpson: Surgical Cases.

Friday.—(At the Royal Infirmary.) Mr. Kennon: Surgical Cases.

MANCHESTER ROYAL INFIRMARY.

Tuesday, May 12th.—4.15 P.M., Mr. W. H. Hey: Indications for Surgical Intervention in Chronic Abdominal Disease.

Friday.—4.15 P.M., Dr. D. E. Core and Mr. H. H. Rayner: Demonstration of Cases.

MANCHESTER BABIES' HOSPITAL, Burnage-lane, Levenshulme Post-Graduate Lectures.

Friday, May 15th.—8 P.M., Miss Herzfeld: Hernia in Infants.

Appointments.

Grout, John Lewis, F.R.C.S. Edin., L.R.C.P. Lond., M.R.C.S., has been appointed Honorary Radiologist and Physician in Charge of the Electro-Therapeutic Department at the Sheffield Royal Hospital.

Oliver, O. H. D., L.R.C.P. & S. Edin., L.R.F.P.S. Glasg., Certifying Surgeon under the Factory and Workshop Acts for the Coxhoe District of the County of Durham.

Smith, H. G., M.D., B.S. Lond., D.P.H. Camb., Medical Officer of Health for Lincoln.

White, Clifford, M.D., F.R.C.P. Lond., F.R.C.S. Eng., Obstetric Physician to University College Hospital.

Paddington Green Children's Hospital: Stobo, A. J. H., M.B., Ch.M. Sydney, House Physician; Morton, R., M.B., Ch.B. Edin., House Surgeon.

Queen Charlotte's Maternity Hospital: Roberts, C. H., F.R.C.P. Lond., F.R.C.S. Eng., Consulting Obstetric Surgeon; Phillips, L. G., M.S., M.B. Lond., F.R.C.S. Eng., Obstetric Surgeon to In-patients; Wilson, C. M., M.D., F.R.C.P. Lond., Physician; and Williams, L. H. W., M.D., M.S. Lond., F.R.C.S. Eng., Obstetric Surgeon to Out-patients.

Vacancies.

For further information refer to the advertisement columns.

Barnsley, Beckett Hospital and Dispensary.—Jun. H.S. £140.

Bedford County Hospital.—Asst. H.S. £130.

Birmingham General Dispensary.—Res. Holiday Locum, 9 guineas weekly.

Cancer Hospital, Fulham-road, S.W.—H.S. at rate of £100.

Cardiff Royal Infirmary.—Res. Reg. and Anæsthetist. £100.

Carmarthen, Joint Counties Mental Hospital.—Asst. M.O. at rate of £350.

Coventry and Warwickshire Hospital, Coventry.—Two Hon. Asst. S.'s.

Darlington County Borough.—Asst. M.O.H. £750.

Dreadnought Hospital, Greenwich.—Anæsthetist. 50 guineas.

Durham County Council, Education Dept.—Asst. School Oculist, £600. Also Asst. School M.O. £600.

East London Hospital for Children, &c.—Morning Cas. O. at rate of £120. Also Anæsthetist. £50.

Elizabeth Garrett Anderson Hospital, Euston-road, N.W.—H.P., Obstet. Asst., and two H.S.'s. Each at rate of £50.

Kensington Tuberculosis Dispensary, 119, Ladbroke-grove, W.—Temp. Tub. Officer for one month. 35 guineas.

Lanark County.—Bacteriologist and Pathologist. £750.

Leicester City Education Committee.—Asst. Sch. M.O. £600.

London Temperance Hospital, Hampstead-road, N.W.—Res. M.O. at rate of £175.

Maidstone, Kent County Ophthalmic Hospital, &c.—H.S. £300.

Manchester City.—Female M.O. £632 7*s.* 8*d.*

Manchester, East Lancashire Homes for Disabled Sailors and Soldiers, Broughton House, Park-lane, Kersal.—Res. Med. Supt. £400.

Manchester Royal Infirmary.—Dickinson Research Travelling Scholarship in Medicine. £300. Also Res. Surg. O. £200.

Manchester, St. Mary's Hospitals.—Hon. Asst. S.

Metropolitan Hospital, Kingsland-road, E.—Surg. for Diseases of Women. Also Asst. P.

Middlesex County Council.—Deputy County M.O.H. at rate of £900.

Middlesex Hospital, W.—P. and Asst. P.
Newcastle-upon-Tyne, Princess Mary Maternity Hospital.—Asst. Res. M.O. at rate of £40.
Paddington Metropolitan Borough.—M.O.H. £1000.
Patna, India, Medical College.—Prof. of Pharmacology, Prof. of Anatomy, and Prof. of Physiology. Each Rs.1200 per mensem.
Royal Northern Hospital, Holloway, N.—P., Two Asst. Dent. S.'s. Also Obstet. S.
Salford Union Infirmary, Hope, Pendleton, near Manchester.—Asst. Res. M.O. at rate of £275.
Sheffield Royal Infirmary.—H.P. £80.
Shrewsbury Borough.—M.O.H., &c. £800.
Stockport Infirmary.—Third Res. H.S. £175.
Truro, Royal Cornwall Infirmary.—H.S. £170.
West Middlesex Hospital, Isleworth.—Asst. Med. Supt. £250.
Winchester, Hampshire County Council.—Asst. M.O.H. £600.
York Dispensary.—Res. M.O. £175.

Births, Marriages, and Deaths.

BIRTHS.

CROCKFORD.—On April 29th, at Terrace Lodge, Axminster, Devon, the wife of A. L. Crockford, M.C., M.B., of a daughter.

FERGUSSON.—On April 29th, at Albert-terrace, Edinburgh, the wife of Dr. A. E. Fergusson, Westcliff-on-Sea, of a son.

POPHAM.—On April 28th, at a nursing home, Harrogate, the wife of Captain Cyril Popham, R.A.M.C., of a son.

RITCHIE.—on April 27th, at Whiteholme, Northwood, Middlesex, the wife of Dr. Douglas Ritchie, of a son.

WAKELY.—On April 27th, at Delmynden, Carshalton, the wife of Dr. A. S. Wakely, of a son.

MARRIAGES.

GIBSON—BEAVER.—On April 30th, at St. Stephen's, Bournemouth, Herbert Robert Burnett Gibson, Major, I.M.S., to Ellen Cromwell Beaver, daughter of the late Milton Stuart, of Liverpool, and widow of Arnold Atwood Beaver, late of Heather Lodge, Bournemouth.

MACBRIDE—ORR.—On April 28th, at Hillhead Parish Church, Glasgow, Henry John Macbride, M.D., of Harley-street, London, to Jean Alexandra, younger daughter of Mr. and Mrs. P. Hunter Orr, Belhaven-crescent, Glasgow.

SHERIDAN—HARRIS.—On April 16th, at Brompton Oratory, Captain Bertrand C. O. Sheridan, M.C., R.A.M.C. to Vera, younger daughter of Mr. and Mrs. T. P. Harris, of Hillfields, Pedmore, Worcestershire.

DEATHS.

AMOS.—On April 27th, at Geneva, Samuel Edward Amos, M.R.C.S., L.R.C.P., of Gazley, Ventnor, I.W., in his 40th year.

WILLIAMS.—On April 24th, at "Hagren," Penyffordd, near Chester, after a short illness, Thomas Gee Williams, M.B., in his 40th year.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

MANCHESTER WAR MEMORIAL BEDS AND COTS.—The War Memorial Committee have an unspent balance of £4082 from the £10,572 subscribed for the war memorial in St. Peter's-square, which cost only £6490. It was agreed that it would be carrying out the spirit which prompted the response if beds were endowed for the use of dependants of soldiers and sailors who fell in the war. The Lord Mayor was authorised to arrange for the endowment of two beds at the Royal Infirmary, and one cot and one bed at the Ancoats Hospital, and a cot at the Royal Manchester Children's Hospital at Pendlebury. When the beds are not required for the specific purpose they may be used as the authorities shall determine. The beds and cots will be called the Manchester War Memorial bed or cot as the case may be.

"BAKERS' ITCH": COMPENSATION CASE. — At Hanley County Court on April 24th, Judge Ruegg, K.C., delivered a reserved judgment of importance to employers and workers under the Compensation Act. A baker, Thomas Starkey, of Stoke-on-Trent, sought compensation from his employers, Messrs. Clayton and Sons, bakers, of Loughton, on the ground that he had contracted "bakers' itch" while in their employ. The judge said it was admitted that Starkey had fully recovered, but the applicant submitted that the moment he went back to work the disease would recur. The judge decided that he could not give a workman compensation in respect of a disease from which he was not suffering, although the disease might immediately recur if the workman resumed his old employment. It was an extraordinary difficult question to consider, the judge remarking that if he awarded compensation it would be compensation for life. The Act never intended that, and he added that if the man did return to baking and the disease recurred, that would be a new accident, which, if proved, would entitle him to compensation. It was intimated there would be an appeal.

Notes, Comments, and Abstracts.

THE TREND OF MODERN HYGIENE.*

BY ANDREW BALFOUR, C.B., C.M.G., M.D., F.R.C.P. EDIN., D.P.H. CAMB.

THE trend of modern hygiene or the modern trend of hygiene—which is the better title? It is a moot point, but, after due consideration, I decided to employ the former for the following reason. While one must admit that, almost from the beginning of time, or at least from the beginning of human history, certain general hygienic principles have remained unchanged, and while one must also agree that much of our latter-day hygiene is a reversion to the practice of the Ancients, yet of late years such a remarkable and far-reaching change has come over both the spirit of our dreams and our actual undertakings that we may, with some justice, assert that a new hygiene has been developed, a modern health campaign possessing features which entitle it to be classed as a distinct entity.

[Dr. Balfour then briefly outlined the practice of hygiene throughout the ages, from the days of the ancient Hebrews to the time when a sanitary conscience began to develop in this country, through the labours of such pioneers as Howard, Pringle, Monro, Lind, Trotter, Shaftesbury, Chadwick, Simon, Southwood Smith, and Snow. These men, he said, found Augean stables to be cleansed, and gradually, as order took the place of chaos, as cleanliness replaced dirt, as the work of the laboratory came to be applied to every-day life, as there was more time for thinking and observation, it became evident that, despite all the progress, there yet remained new worlds to conquer. Thus modern hygiene was born. He continued :]

Education of the Public.

The most important item in the public health campaign is, beyond all doubt, education; not so much education of the medical student, the medical man, the dental surgeon, the veterinarian, or the sanitary inspector, as education of the lay public. It sounds simple, but in reality is beset with many difficulties, and perhaps the chief obstacle which lies in the way is the innate selfishness which seems to pervade such a large section of the community on these matters. It must be remembered, however, that sufficient time has not yet elapsed for the effects of the new hygiene to be generally apparent. Striking results have been obtained and are being obtained, but it will take at least a generation before any great and universal effect will be visible, and our modern activities have not been in full swing for five-and-twenty years.

A gratifying feature of the educational campaign is the number of voluntary agencies striving to impart knowledge and to popularise scientific endeavour as applied to the public health. No less than 23 of these embassies of health, as perhaps we may call them, all operating from London, are listed by Sir George Newman in his important memorandum on Public Education in Health, and there are others scattered about the country. They are concerned with various lines of activity and, doubtless, accomplish much good work, but the tendency nowadays is to make health departments responsible for the dissemination of information. This is a duty which, of course, has been shouldered by the Ministry of Health in this country, and which has also been undertaken by the health departments of various municipalities, as witness the legends which now appear on lamp-posts and the posters and pamphlets which warn and guide the citizen.

Dr. Dru Drury, speaking on public health in his address at the Nineteenth South African Medical Congress, says: "We must learn to think so naturally, as members of a community, that we shall feel at least as much self-reproach in publishing rotten books or spreading infection in a school, in spoiling a landscape with refuse, or wasting water, in overworking servants or driving with an open exhaust, as we do now in eating peas with a knife or dropping aitches."

Periodic Medical Examination.

The question of life insurance brings to mind quite another kind of education and a new trend of hygiene. Human nature being what it is, a considerable section of mankind is more influenced by what we may call financial education than by any other means. Demonstrate material monetary benefits resulting from hygienic measures and you may carry the day. Life insurance companies have of late years realised this cardinal fact, and some of them now operate, as Dr. Otto May has pointed out, in three ways. At least, certain of the American companies do. Here we are more conservative and cautious, while, of course, National Health Insurance has been established in this country and, to some extent, proceeds along the lines which a company like the Metropolitan Life Assurance of New York has followed. Some of the advisory medical officers to British companies, including Dr. May himself, are not yet convinced of the utility of all the American undertakings. These latter are of a tripartite nature and may be listed shortly as propaganda, the endowment of research, and individual case treatment. The last named connotes periodical medical examination of policy-holders.

---

* Abstract of a paper read before the Royal Society of Arts on April 29th, 1925.

The first two are beyond criticism, but the success of the third is imperilled, partly because it is difficult and expensive to establish a really effective diagnostic service, and partly because a lack of interest is apparent amongst policy-holders. They submit to a first examination impressed, perhaps, by its novelty, but few present themselves for a second and still fewer for subsequent overhauls. Hence, Dr. May and others believe that in this country insurance companies had better confine themselves to supporting voluntary health organisations. It would seem that the time is not yet ripe for the above-mentioned development, although it was suggested in England by Dr. Dobell as long ago as 1870. There is always a pioneer in matters hygienic, a John the Baptist, and in this question of periodic physical examinations Dobell played a part like that filled by Robson in connexion with the control of venereal diseases. Both were like voices crying in the wilderness.

That such a consummation is highly desirable, that it may have far-reaching results, and that it should react on the health of the community, is emphasised in a typical American manner by Dr. John Dill Robertson, of Chicago. He does not hesitate to charge the general practitioner with criminal negligence, hoping that his message will prove so irritating that it will stimulate him to a sense of his responsibilities as a guardian of the public health in his own special direction. According to Robertson, who, of course, merely voices in rather a strident tone the views of others, the true function of the private practitioner is not to cure the sick, but so to advise his patients, or, rather, his clients, that they will remain in good health. Away back in 1907 the same argument was advanced as forcibly by Dr. John McVail in a memorandum accompanying his report on Poor-law Medical Relief in England and Wales. In a recent address he developed his theme and indicated seven directions in which the family physician might be of service as a valuable ally of the medical officer of health.

The Ideal Family Doctor.

I cannot here quote him in full, but he deals with the doctor as a historian, an inquirer into family history, and as an observer and checker of tendencies towards general disease. Let it be noted that amongst the diseases mentioned figure obesity and alcoholism. He envisages the physician as a health guardian of the child, a watchful attendant both of mind and body, a corrector and remover of defects, an adviser to the parents. He traces the extension of this medical care to the youth and the maiden, when the practitioner should guide as to work and athletics and be upon the qui vive to remedy faulty tendencies of all kinds at the threshold of adult life. He pictures him as the friend and confidant of the woman, saving her from the special troubles besetting her sex, and watching the adult man, to see that he does not develop some trade disease, strain his heart, or damage his respiratory organs. In addition, he speaks of general examinations like those for which Dr. Robertson pleads, and he figures the doctor as a prop for old age trying to ward off apoplexy and stay the morbid processes which too often make the evening of life a tragic misery. Dr. McVail is careful to point out that the doctor can only assume such a rôle with the consent of the individual—the adult for himself, the parent for the children.

A specific application of this fine ideal, an ideal which, as we will see, requires certain developments or ever it can come to maturity, is seen in the investigation of "golf hazards," by Dr. Lieb, who, startled by the occurrence of sudden deaths upon the links, collected data which he incorporated in a paper published by the *New York State Journal of Medicine*. Dr. Lieb found that in every case organic disease was present, and that the golfing was only an accessory factor. The important point, however, is that, had those who perished undergone periodical physical examinations and had ordered their lives in accordance with the findings, they need not have died.

Faults in Medical Education.

Now while, presumably, the majority of medical men at the present time could be trusted to give a sound opinion on the middle-aged golfer, it is by no means so certain that they could adequately fulfil the duties listed by Dr. McVail. They have been reared, be it remembered, in an atmosphere of curative medicine, and they have not been trained to look for the beginnings of disease. Of course, amongst them there may be a few James Mackenzies with the seeing eye and the understanding heart, but, taken as a whole, the general practitioner is a patcher, not a preventer. That is not his fault. In the past his training has been defective.

For one thing, he has struggled through a series of more or less water-tight compartments. There has been little linking up of his early scientific knowledge with his later medical and surgical studies, and, if he is to act effectively, his medicine and surgery must be leavened with a leaven wherein physics, chemistry, biology, anatomy, and physiology are combined as ingredients, together with sympathy and common-sense. For another, the doctor, as a student, has been so crammed that too often one mass of ill-digested facts has, throughout the curriculum, crowded out another in process of assimilation, and the only wonder is that he has emerged sane and sound and with a modicum of useful knowledge. For yet another, the preventive aspects of his life's work have not been explained to him, and the vast possibilities which lie before him are too often as a sealed book.

Now all this is changing. The beginnings of that change are recounted in the masterly treatise by our distinguished chairman, his memorandum entitled "Recent Advances in Medical Education in England," or, as he might have written, "Great Britain," for he cites Scotland again and again, and the old Alma Mater which I had the honour to share with him. Sir George Newman and others have remembered what happens when the blind have blind leaders, and by degrees a new type of doctor should be evolved, who, it is to be hoped, will combine the acumen of the old clinical observer with the broad outlook of the sane scientist.

What We Eat and Drink.

One of the most significant happenings in the modern health campaign is the attention paid, not only to dietetics, but to food preservatives and to the handling of food-stuffs. The layman, I fear, must be a little bewildered by all that is said and written about diet. Screed succeeds screed on vitamins. Here an authority thunders against butchers' meat and starchy foods, there an oracle condemns milk for adults. We read of human cesspools. We are told that our faulty food habits explain the increase of cancer. At times one wonders how the human race has managed to survive at all, and exclaims with Pontius Pilate, "What is Truth ?" And yet we are progressing, for we are beginning to understand the relation of diet to endocrine secretion and we are correcting errors into which we have drifted through non-adaptation to our complex surroundings, through failure to understand that what the primitive man can do with impunity the civilised man, or at least the town-dweller, does at his peril. The truth really lies in moderation, for, in a phrase I once coined and which perhaps will bear repetition, it is still the case that many folk by their copious libations wash themselves into graves which they have dug with their own teeth. Copious libations do not signify wholly, or even mainly, the imbibition of alcoholic beverages, for a vast deal of digestive trouble is brought about by excess in tea and coffee drinking, and by the swilling of liquid, frequently in effervescing form, during meals. Most of us after middle-age eat far more than we require. War experience should have taught us a salutary lesson, but, like other lessons, it has been forgotten.

I am inclined to think that eventually the chief value of the scientific tirade on foods and feeding will be found to lie in the fact that it will teach some sections of the most important class of the community—the workers—how to live cheaply as well as healthily, how to get the best food value for money spent. This in itself is a great matter, for the waste at present is enormous. Remember, however, there are many poor housewives who, on the practical side, could give the scientist points.

Coöperation in Hygiene.

We have seen how voluntary organisations coöperate with official agencies, how health authorities should coöperate with the lay press, how insurance companies try to coöperate with their policy-holders, how the doctor must coöperate with his clients, and we might also have considered the coöperation of the employer with the employed, but perhaps the most significant trend in modern hygiene is that international coöperation which has sprung into being since men ceased slaughtering each other. True, there was international coöperation prior to the Great War—quarantine is an old story—but there has never previously been a union of peoples on a large scale, not solely for the purpose of safeguarding themselves from the ravages of disease, but with the avowed intention of stamping out disease, wherever found, and of spreading light and learning. It is a fine conception, and is seen in its highest development at Geneva, where the Health Section of the League of Nations is engaged upon its beneficent and widespread work, and in the foreign operations of the International Health Board of the Rockefeller Foundation, for these, though of American origin, depend upon collaboration with other nations.

There is much to be learned from international coöperation, for, after all, the British Empire is a congeries of nations and, apart from any other consideration, anything which serves to bind them more closely in bonds of amity is not only desirable but essential. Surely health considerations should be as potent a tie as financial links! At any rate, they are less mundane and more altruistic.

Black Spots of Empire.

We do not deserve to own some parts of our possessions, for at the present moment, from a hygienic standpoint, they are a disgrace to the British flag. I have no hesitation in saying that the Americans are justified in the feelings with which they view most of the British West Indies, and that the Dutch are more than justified in looking upon some of our hygienic efforts in the Far East with a kind of pitying contempt. Is this a fitting position for the Empire which bred a Simon, a Chadwick, a Patrick Manson? Let us not underestimate the difficulties, let us not overlook how much has been accomplished, above all, let us take into consideration what is now being done and be thankful that there is much to our credit; but, at the same time, as we cannot now lead in the coöperation movement, let us imitate it and improve upon it within the confines of the Empire. Is it not significant that on the other side of the Atlantic a Pan-American Sanitary Code has been formulated to which no less than 18 nations are now adherents?

The conditions in a country like India are such that I sometimes think it would be well if the practice of hygiene there and in some other lands assumed the aspect of religious exercises. There are many forms of worship inferior to that of the goddess Hygeia, and if only the devotions could be adapted to the mentality and habits of the people, I believe more benefit would accrue than from all the efforts now made.

In Africa the case is rather different, and at the present time a great effort is being made to educate the African along sound lines. The trend is towards creating native hygienists who will be able to aid in the sanitary salvation of the Dark Continent. I have no doubt, from what I have seen, that this is capable of accomplishment, though it will take time and money. What the Americans call "visual education" is badly needed, and whether this be accomplished by the cinematograph, by diagrams and models in the schools, or by the establishment of graphic museums, care should be taken that it is not neglected in any scheme for native training.

The Future.

Lastly, both at home and abroad, stress should be laid on the financial aspect of public health work, and the ultimate aim of the hygienist should be clearly and definitely stated. The monetary value of sanitary endeavour is a very tangible thing, and statistics are now available regarding many lines of health work which are most impressive and should convince all save the cranks and the wilfully ignorant. Thus, taking industry, which is so closely related to finance, we know, beyond all manner of doubt, that attention to mental hygiene in factories and workshops promotes harmony and leads directly to a larger output.

A hopeful sign is that there is much enthusiasm and no little idealism in public health circles, and, so long as these are well regulated, they cannot fail of their effect. Yet it is wise to bear ever in mind the dictum of Rienzi and the wisdom of Adam Smith. Rienzi wrote: "The prudent man may direct a state, but it is the enthusiast who regenerates it or ruins," while Adam Smith, in his "Wealth of Nations," before the dawn of the so-called scientific era, declared: "Science is the great antidote to the poison of enthusiasm and superstition."

MICROSCOPY OF THE LIVING EYE.

WE have previously had occasion to refer to recent methods of examining the structure of the living eyes under high magnification with the aid of illumination from the slit-lamp. To get full value from the apparatus it is necessary to serve an apprenticeship in its employment, just as it is necessary for the medical student to learn the use of the ophthalmoscope. For the last few years Prof. Alfred Vogt, of Basle, has conducted classes each summer, which have been attended by ophthalmologists from all over Europe. We now hear that Mr. Basil Graves, who has devoted much time to this subject at hospitals in London, is conducting similar classes in America under the auspices of the Graduate School of Medicine of the University of Pennsylvania. The ophthalmologists who attend these courses are divided into groups of six or nine and each course consists of ten lectures followed by practice with the instrument. This invitation to Mr. Graves was originally for three months, but has been extended to six. It looks as though American ophthalmologists were preparing to take the lead in the discoveries which some slit-lamp enthusiasts anticipate.

CHRONIC ULCERATIVE STOMATITIS.

To the Editor of THE LANCET.

SIR,—In reply to Dr. Meadows (THE LANCET, April 18th) my experience has been that these cases yield readily to dieting. It is necessary to interdict sugar in any form, and also to limit the quantity of fats taken. I allow butter to be taken freely, but no fat of meat, no bacon, no cream, and no milk as a beverage, although the latter may be taken in tea or coffee. Plenty of fresh butcher's meat should be taken with potato and green vegetables, but no fruit, and, of course, no sweet puddings or pastry. Fish and eggs are also suitable. I have not found any medicine of much service, and for local treatment I prefer nitrate of silver applied daily to the ulcers until they are nearly healed.

I am, Sir, yours faithfully,

A. LESTOCK REID.

Brook-street, W., April 22nd, 1925.

DISSEMINATION OF GERMS.

To the Editor of THE LANCET.

SIR,—It seems to me, and has done so for years past, that this subject is one for widespread propaganda by the Ministry of Health. Within my memory spitting in public places has been abolished. Why not this equally objectionable habit? The exhibition of your excellent picture (THE LANCET, April 25th, p. 904) on all trams, trains, and omnibuses would doubtless cost money. But how much illness, unhappiness, and working capacity would it not save? If all medical men, including medical officers of health, would do as I intend to do, and have copies of your article and picture printed and circulated amongst their patients, much good would result I am convinced.

I am, Sir, yours faithfully,

May 2nd, 1925. M.D., B.S.

THE GOAT.

THE keeping of goats is looked upon by some as a hygienic duty, even more than as a profitable hobby, for goats are highly resistant to tubercle. No statistics are available for the British Isles, but in Holland, where goats are not kept under the best conditions, during 1911–20 out of a total of 59,188 animals slaughtered only 54 were found to be suffering from tuberculosis. The milk of the goat is rich in protein and fat and, as Dr. B. D. Z. Wright points out in the British Goat Society's Year Book,[1] is tolerated by some children who cannot take cow's milk. There is also less chance of fæcal contamination of the milk. The Year Book contains a number of very practical articles on goat-keeping, and a good case is made out for improving the goat's position in the agricultural life of the country.

THE "VIC" TONIC FACE CLOTH.

WE have received from Messrs. Grout and Co., Norwich, a face cloth, loofah-like in texture, which should be a useful toilette adjunct; the friction to the skin on its employment is delicate, while the softness of the fabric makes the smallest folds accessible. When soaped it does not get slimy, a fault with many face cloths, and its small size is an advantage to the traveller. Each cloth is wrapped in a sealed envelope and is sold at the price of 1*s.*

A DANGEROUS DEVICE WITHDRAWN.

WE are informed that owing to protests made on behalf of the medical profession the device—a sponge designed for insertion into the vagina during menstruation—to whose dangers we drew attention in THE LANCET of April 18th, has been withdrawn from sale, and remittances for purchase already sent are being returned. This public-spirited action on the part of the company responsible for its manufacture deserves praise.

SHAVALLO.

THIS is a shaving soap prepared by Messrs. J. Knight and Co., Ltd., Royal Primrose Soap Works, Silvertown, E., which has many of the properties which careful shavers look for: it is bland, makes a good lather and is pleasantly scented. The preparation is supplied in a convenient little celluloid case from which it should not be removed, as the roll of soap can be moved up and down within the case by pressure from the bottom.

Enquirer.—We understand that Vitaglass, made by Mr. Lamplough, 47, Victoria-road, King's Norton, is transparent to ultra-violet rays as short as wave-length 275$\mu\mu$. This is rolled cathedral glass suitable for veranda roofs, shelters, skylights, and upper parts of windows. It is hoped to use it for bulbs of tungsten filament lamps which might then be employed as mild sources of ultra-violet rays. As sheet glass the cost is 3*s.* to 4*s.* a square foot.

Fine Pure Wool Sheets

It might be thought that a woollen sheet can only be a modified blanket and, therefore, not quite suitable; but this is not the case.

Jaeger Pure Wool Sheets are made of a fabric much lighter and smoother than the flannel which is very often worn next the skin. They are, in fact, as smooth as linen or cotton, with the advantages and comfort which wool gives. They are warmer in the winter, and cooler in the summer, because wool is a slow conductor. To the invalid a wool sheet is of special value, but anyone of good health, who has also tried one, never abandons it, if only on account of the luxurious ease which a Jaeger Sheet gives.

White Wool "Taffeta" Sheets for Single Bed **43/6** each; for Double Bed **75/-** each.

JAEGER
Pure Wool

Patterns sent on application.

THE JAEGER CO. LTD.
95, Milton Street, London, E.C.2.

Essential in the Bathroom.

TONIC VIC
Face-cloth

not only washes the skin thoroughly free of all dust and powder; it has a tonic action which gets right down into the delicate skin tissues where real complexion beauty is built. Quite different from ordinary face-cloths, it is always hygienic, never gets "slimy," and makes the skin healthier and lovelier after every wash. Hand size 1s., Bath size 1s. 6d., in hygienic sealed envelopes.

Sole Manufacturers:
GROUT & Co., Ltd.,
Great Yarmouth.
Stocked by all leading wholesalers.

NORVIC
(Regd.)
Crêpe Binders
are invaluable in maternity and all cases where adaptability, elasticity and support are required. In 6, 8 & 11in. widths.

Memorial Lecture

ON

LISTER'S GREAT ACHIEVEMENT.

Delivered before the Royal College of Surgeons of England on May 14th, 1925,

BY SIR W. WATSON CHEYNE, BART., K.C.M.G., D.SC. OXF., LL.D. EDIN., F.R.C.S. ENG., F.R.S.

MR. PRESIDENT, LADIES AND GENTLEMEN,—Before I begin this lecture I should like to say how much we all regret the sudden death of Sir Rickman Godlee, which has cast a gloom over to-day's proceedings. Sir Rickman Godlee took a very active part in the Lister Memorial funds and was, I know, looking forward very much to the proceedings to-day. I also had been looking forward to meeting him. Sir Rickman Godlee and I were very closely associated for many years as Lister's private assistants, and a more delightful, able, and loyal colleague I cannot imagine. I am sure that everyone here sympathises most sincerely with Lady Godlee in her great bereavement.

I must thank the Council of this College for the great honour they have done me in awarding to me the first Lister Memorial Medal and Prize. I need hardly say that the medal commemorating my great master and friend will be one of the most treasured of my possessions.

The subject of the lecture which must be given by the recipient of this honour is left entirely to his judgment and will naturally in the future refer in the main to work in which he has himself been principally engaged. But on this occasion I feel convinced that as the first recipient of this honour, and as one of the little band of men[1] who knew Lister and his work most intimately, and who had the extraordinary good fortune of being closely associated with him throughout his great achievement, I ought to put on record matters connected with his work and not especially concerning myself. I hope that my decision will be acceptable to you.

As a matter of fact, I have for some time had a great desire before I depart this life to place before the profession as fair a statement as I can of Lister's great achievement, his aims, the principles on which he started, how they became modified as time went on, and the final result. Having, however, practically given up active surgical work I have felt more and more diffidence in laying before the profession a story which to some may appear to be past history and not of any actual living value at the present time. This award, however, provides the stimulus, and indeed the immediate necessity, for carrying out my desire. The story I have to tell, though going back for just 60 years, is one still full of vitality, of instruction, and of the gravest importance to surgery. It is far from being a closed book, the whole matter is still fluid, perfection has not yet been obtained in all directions; indeed, at the present time the tendency seems to be rather to remain satisfied with what has been achieved than to continue the effort to obtain perfection.

When I came to write a lecture on these matters in full I found that, even after cutting it down as far as possible by omitting extensive passages and by condensing others very much, its delivery would far exceed the time at my disposal and try your patience to breaking point. At the same time I wished to make it complete, and I have, therefore, attempted to solve the problem by taking out of the original lecture the more personal matters which seem most suitable for a general discourse (and my own experience is that the less the dry detail in a lecture the more successful it is) and publishing in the same volume with this discourse as an appendix the remainder of what I wrote originally, which can be perused and pondered over at leisure.

THE FIGHT AGAINST SEPTIC DISEASES OF WOUNDS.

The story that I have to tell to-day is one of the most fascinating tales that I know of and far exceeds in interest the most exciting detective story ever written. And its influence on the life and health and usefulness of mankind surpasses all imagination; and it is a true story. It is the story of a fight against a series of diseases—the infective or septic diseases of wounds—which have attacked wounds probably since the world began. As a matter of fact, any wound of the skin, whether as the result of an accident or of an operation deliberately performed by the surgeon, involved up till Lister's time a very great risk to the patient of serious illnesses called "septic diseases," which, indeed, very often proved fatal. And although numerous attempts had been made by surgeons of all countries and through many ages to discover the cause and to find a remedy for these diseases, no real progress was made till Lister took up the work. Up to that time a surgical ward in a hospital was a place in which the most of the patients were visibly ill, with flushed faces, parched lips, delirium, severe pain, &c., and many of them were evidently on the verge of death; the wards were pervaded with a peculiar mawkish odour which was very trying to newcomers. I suppose very few here to-day remember those days. What a contrast to the surgical ward of to-day with its fresh air, happy and contented patients, looking as if nothing had happened to them, and very slight mortality. This we owe to Lister, and much more, for not only has his work led to the practical disappearance of septic diseases after operations, but it has enabled the surgeon to perform many operations which prolong life, restore movements, rectify deformities, and add to the usefulness and comfort of mankind.

Lister's first introduction to septic diseases was when he became a dresser in the surgical wards at the University College, London. I think that his very first case had been attacked by phagedænic gangrene, one of the most terrible of these septic diseases. That and other similar cases impressed him so greatly that he never forgot them, and always felt that no study was more urgent or might be more fruitful than the attempt to find out the cause, the prevention, and the best methods of treatment of these septic diseases.

SEPSIS AND PUTREFACTION.

We may here pass over his earlier years and come to the time when he was professor of surgery in Glasgow University and was appointed one of the surgeons at the Glasgow Royal Infirmary. This was late in 1861, and by that time Lister had done excellent experimental work on the early stages of inflammation, coagulation of blood, &c.—work which was to be of the greatest value to him in future and for which, I may add, he had been elected at the early age of 33 a Fellow of the Royal Society. At this time he had come definitely to the conclusion that sepsis was closely bound up with putrefaction of the blood and discharges in the wound, and that if he could only prevent this putrefaction septic diseases would in all probability disappear; the cause of putrefaction was, however, still unknown. Most surgeons attributed it to the action of the gases of the air, especially of the oxygen, on the organic fluids in the wound, while others pre-supposed the existence and action of indefinite bodies which they called "miasms" and which were supposed to develop in unhealthy regions and pass into the air. On the oxygen theory many attempts had been made in former years to prevent the access of air to the wounds, but without any improvement as regards sepsis, and on the assumption that the gases in the air, or the "miasms" in the air which were also supposed to be gaseous, were the cause of the trouble Lister could not devise any remedy. Lister, however, made an extensive experiment in his wards with ordinary cleanliness but without success, and one can quite imagine his depression when he found that the best methods that he could think of did not help him at all and that pyæmia and all the other septic troubles dogged his footsteps and rendered his best work nugatory.

---

[1] In Glasgow, Lister's private assistant was Sir Hector Cameron who, I am glad to say, is still well and active; in Edinburgh his assistant was Dr. John Bishop, who died shortly after Lister went to London—a most lovable man and deeply regretted by all who knew him. In London his assistants were the late Sir Rickman Godlee and myself.

THE ORIGIN OF LIFE.

But it so happened, though Lister did not then know it, that the cause of putrefaction was being revealed about the time that he was appointed professor of surgery in Glasgow. For over a century a very interesting and sometimes a very heated controversy had gone on as to the origin of life, and in the first instance the controversy was carried on chiefly by priests. Indeed, I presume that it began on some such theological problem as this: Was there only one creation of life as suggested in the Bible, or is it possible that the conglomeration of certain atoms in certain ways would, shall we say, attract the vital spark (just as an electric current may be set up by the contact of various metals) and that in this way a new living organism might be produced? The advocates of the latter view, which came to be spoken of as "spontaneous generation," sought to support their opinion by elaborate experiments which were quickly disposed of by their opponents but only to lead to a fresh crop of experiments. One would never have thought that such an abstruse matter would have any practical influence on commerce and still less on the lives and health of living beings. As regards the former, however, the subject of fermentations became involved and it then became a matter of importance to chemists. About 1860 Pasteur not only closed the proof against the spontaneous generation of yeast cells, but also, I believe, quite unwittingly opened up a new and, as it ultimately turned out, an extremely vital line of research by pointing out that other fermentations apart from the vinous, such as the butyric and the putrefactive, were also dependent on living organisms which gained access to the putrescible fluids with the dust in the air or on surrounding objects and especially from other putrefying media. Pasteur himself does not seem to have had at the time any idea of the importance of this part of his investigations, and as far as I can ascertain only three men thoroughly realised it or at any rate made any attempt to utilise the knowledge within the next few years. These men were Jules Lemaire, Spencer Wells, and Joseph Lister. It will be of interest for the moment to sketch out what each of these men did with the knowledge which they acquired from Pasteur's work; in doing so I do not want in any way to compare these three men, but, as a matter of fact, just as no two persons have exactly the same finger-prints so I believe that no two persons have exactly the same arrangement of brain, and as thought and action are the results of the working of the brain no two persons will take exactly the same steps in the solution of a problem. Thus it is very interesting to compare the result of the action of different types of brain.

CONCLUSIONS OF VARIOUS OBSERVERS.

Jules Lemaire was, I fancy, of the type of the delightful, old, learned family doctor. He was evidently good at surgery, but he had no surgical hospital appointment and so had not the opportunity of testing any views he may have formed; he was also much interested in scientific matters. He saw at once that Pasteur's statement as to the cause of putrefaction was of great importance. He wrote quite a good deal on the bad effects which might arise from bacteria, and he washed his wounds with various antiseptics, notably with carbolic acid, with the view of interfering with the growth of bacteria in the discharge. He never, however, suggested, as Lister did, that these antiseptics should be used to kill the germs before they got a footing in the body or in the wound, and he spoilt his case by advocating the use of carbolic acid for all sorts of diseases. Evidently Lemaire's advocacy of carbolic acid had attracted attention, for Declat thought it worth his while to claim priority in the use of the drug.

Something like three or four years elapsed, and then I find that Spencer Wells, one of the pioneers in ovariotomy and subsequently President of this College, in an address at the meeting of the British Medical Association in 1864[2] gave a most excellent description of Pasteur's work and its bearing on surgery. I do not think that a better résumé could have been made. Spencer Wells was a great practical surgeon and a bold operator, but, curiously enough, he did not follow up the logical conclusions that he drew from Pasteur's works. Indeed, his only remark as to the practical application of the work to which he called attention was that "surgeons should always secure the most scrupulous cleanliness and purity of everything surrounding them," and as regards any other treatment he advocates the internal administration of sulphites in the form of sulphite or hyposulphite of soda. There is no doubt that the recognition of the value of scrupulous cleanliness in the sense of preventing the putrefactive germs from getting a footing was a very important advance, but a good deal more was needed for perfection.

The third man, so far as I can find, who took up Pasteur's work was Joseph Lister. I cannot make out exactly when this knowledge first came to him, but I fancy it was in 1864. I understand that he was walking home with his colleague, Prof. Thomas Anderson, the professor of chemistry in Glasgow, one afternoon towards the end of 1864, discussing putrefaction and its causes, when the latter suggested that he should read certain papers on fermentation and spontaneous generation which had been recently published by a rising young French chemist, Louis Pasteur. Lister, who naturally was not conversant with chemical literature, had not heard of Pasteur's work, nor had he followed the controversy on spontaneous generation, but he at once got these papers,[3] and from the perusal of them he found that Pasteur's experiments showed that it was not the gases of the air that the surgeon had to fear but minute living particles floating in the air and settling on surrounding objects in the form of dust. And he learned further that so long as these particles were excluded from the putrescible material after it had been boiled there was no sign of living organisms or putrefaction in the material. As soon, however, as the protection was removed and the dust was allowed free admission, minute bodies belonging to the lowest class of vegetable life could be seen swarming in the fluid, and putrefaction very quickly set in. The conclusion was that some of the particles which were excluded by filtration or destroyed by heat were actually living germs which, as they developed in the putrescible material, set up the putrefactive fermentation just as the vinous fermentation was only set up on the admission of living yeast cells.

One can well imagine Lister's excitement and delight when he realised from Pasteur's work that the enemy with which he had to deal was not a gas present everywhere and practically impossible to get rid of or avoid, but living solid particles floating in the air or present in the dust, capable of being killed or avoided—still a difficult problem no doubt, but not an insoluble one. These "germs," as they were called for a long time, were new to him and to the surgical profession generally. Long rods, known as vibrios, were comparatively easily seen swimming about in putrefying fluids, and also small rods and round bodies, but they had not been specially studied, and to many it seemed the height of absurdity to suppose that such minute bodies could be of any practical importance to the surgeon.

LISTER'S APPLICATION OF PASTEUR'S WORK.

I do not think that at this time Lister, nor indeed anyone else, had any very definite idea as to the *modus operandi* of these germs. It was enough for him for the time being that they were the cause of the putrefaction of the discharges from the wounds and that the putrid fluids were somehow or other, if not the cause, at least very closely associated with the causes of local and general septic diseases. Lister's application of Pasteur's statements was: (1) That these germs must be prevented from getting into wounds during and after operations and that they must be killed if possible outside the wound; (2) that if they have succeeded in getting into a wound before the case is seen by the surgeon, as in compound fracture, they must be killed if possible before they have had time to spread and secure a footing, and further germs must be prevented from entering the wound afterwards.

Lister's method of dealing with the information gained from Pasteur's work was thus more definite and more drastic than the suggestions of the other two surgeons referred to, and reflects the action of the philosophical and experimental type of brain. He never swerved from his first decision that the aim of the surgeon must be the prevention of the entrance of living germs into the wounds or their destruction, if possible, before they can gain a footing. But it will be seen that as time went on he found that it would suffice under certain circumstances, especially in the interval between the dressings, to inhibit their growth without necessarily killing them. That his suggestion was the most fruitful of the three is evident from the further course of events.

On further consideration of the various ways of commencing this work it seemed to Lister that it would be best to select cases where the germs had had an opportunity of getting into the wound before the patient came under treatment, but where only a short time had elapsed since the injury, so short that the germs had probably not yet had time to gain a firm footing. Such cases were compound fractures, where the patient comes under the surgeon's care shortly after the accident, with the wound already infected, cases which were notoriously extremely dangerous, large numbers of patients with compound fracture dying of septic disease. In a vast experiment affecting the whole domain of surgery, such as the facts suggested to Lister, the responsibility of the surgeon was at the beginning, of course, very great lest instead of doing good he should make matters worse, but in compound fractures the prospects of the patients could hardly be made worse, and there was a very considerable chance that they might be much improved. And, in addition, the experience that he would gain in treating compound fractures might help him in dealing with operation wounds, which was a larger and much more complicated problem. Besides, except in very urgent cases, operations through unbroken skin could be delayed till he saw what happened in compound fractures.

As regards the procedure, all the laboratory experiments on fermentation and spontaneous generation had so far depended on the employment of heat to kill the germs or on filtration of the air to remove them; but neither of these plans seemed suitable for the present purpose, and therefore Lister turned his attention to chemical substances in the hope of finding one which would kill germs without seriously injuring the tissues exposed in the wound. Curiously enough, during 1864 he had been attracted by a notice in the newspapers about the remarkable effects on the sewage of the town of Carlisle by the use of carbolic acid, a small quantity not only preventing the smell, but also apparently destroying the entozoa which usually infected cattle fed on the pastures on which the sewage was placed. Prof. Anderson obtained for him a supply of this acid, which was sold under the name of German creosote. This substance was very impure and did not dissolve at all well in water—in fact, Lister stated at first that carbolic acid was not soluble in water, but later on, when he got a purer specimen, he found that it dissolved readily enough up to as much as 1 part of the acid in 20 parts of water, and in linseed oil in almost any proportion, but that the oily solution did not seem nearly so active as the watery one was.

It so happened that Lister had to wait a considerable time before suitable cases for his purpose were admitted to the wards. In fact, he had to wait something like ten months before his first real attempt at treatment was made. While we are waiting for the case of compound fracture to come into the ward I may occupy the time by giving you some account of the man himself and of the chief influences on his life.

LISTER AS A MAN.

I like to think of Lister, with his courtly manners and indomitable courage, as one of the knights of olden times sallying out single-handed to find and destroy a formidable enemy, armed with a great but imperfect generalisation or rather working hypothesis and a bottle of crude carbolic acid so impure that he tells us in his first paper that carbolic acid was insoluble in water. He had never seen the enemy, but he saw his ravages on every hand; he did not know how he acted in producing diseases; he did not know where he lived or how he lived. All he knew was that he was probably a unicellular body belonging to the vegetable kingdom and of extreme minuteness, not exceeding more than 1/20,000th of an inch in diameter. He knew nothing about the protective arrangements of the body so much spoken about at the present time. It is, I fancy, well that he did not, for he would have been so bewildered among the various ways in which it is supposed that the enemy on the one hand and the animal forces on the other act, that he would not have known where to strike and he might have failed completely. All that he cared for or needed to know was that he had a terrible enemy who, however, probably had his vulnerable point, and that the gain was so great if the battle were won that it was well worth while to devote his whole mind and his whole energies and his whole life to the solution of the problem.

And it was a great fight, not merely in studying the tactics of the enemy and in devising better and better means of preventing his access to the wounds and in counteracting the effects of his growth and multiplication, but also in overcoming great and unaccountable prejudice, ridicule, and obloquy. This fight was one which few could have carried out to its end, but Lister's profound conviction of the truth and value of what he was battling for—viz., the abolition of sepsis on the lines laid down in his writings—and of the enormous benefit to mankind if the problem were successfully solved, enabled him to put prejudice and ridicule aside and leave the verdict to the future. But he was much helped by a variety of circumstances.

He was mentally well fitted for the task which he had undertaken. He had one of the attributes of genius well developed—viz., that he did not overlook apparent minutiæ. Nor was he led away by the absurd copybook proverbs—" There are exceptions to every rule " and " The exception proves the rule." If he found an exception to a supposed rule he wanted to know why; he did not pass it over as if it were merely an exception and of no consequence. Pasteur had this faculty perhaps still more developed and Koch in a lesser degree,[4] and with all three some part of their success depended on the fact that they were not content to regard deviations from the ordinary course as trifling but wanted to know why these deviations occurred, and in doing so came across unexpected and helpful information.

Lister's Conscientiousness.

Further, Lister had a very logical brain and a very open mind, he was ready to modify his views and plans at once if proper evidence demanded it. He was full of sympathy for suffering and would devote himself to the relief of a patient without consideration of time. I think that probably his greatest characteristic was his conscientiousness. Before he took action on any point he turned the matter over and over in his mind so as to be as sure as possible that his action was right. His conscientiousness had a very curious result as regards his public appearances; indeed, he became rather notorious for being late when he had an important address to give, the reason being that on thinking over what he wished to say something was apt to occur to him at the last moment which he thought he ought to verify before he spoke. I remember when he gave the Bradshaw lecture here that the Council assembled, but there was no sign of the lecturer, and at last they filed into this room and took their places so as to calm the audience, but he was still missing. I was sitting on the back benches, and spying me, messengers were repeatedly sent up to me to ask what had happened to Lister and if he was coming; I could only say that I had left him at 3.30 and that he was then quite ready, but sure enough at the very last moment something struck him which he felt that he ought to look into before he came down.

I have been told that on one very important occasion, when he was giving an address on coagulation of the blood, an idea occurred to him in the carriage on his way to the lecture hall and that he turned into a butcher's and had an animal killed and the observation made before he went on to his lecture. And in his private practice I have known him to be an hour or two late for a consultation, and sometimes when he ought to have been at his house for his appointments he would look in at his nursing home in passing, and if anyone said that they did not feel quite comfortable he would take off his coat and readjust dressings or splints quite regardless of the fact that his waiting-room was full of irate doctors and patients vowing that they would never consult him again.

Family Influence.

But apart from his own endowments which he was constantly improving by hard work, he was one of a family of exceptionally able people. Especially did he owe much to the influence of his father, who was especially interested in optics, which were his chief hobby and recreation; indeed, it was he who developed the achromatic lens, and for his work in this direction he was elected a Fellow of the Royal Society. In Godlee's charming life of Lister he reproduces much correspondence which took place between father and son and which shows their great intimacy, the care with which he kept his father acquainted with all the work that he was doing, and the wise counsel which his father gave him.

And then the whole-hearted way in which his wife entered into all his work and acted as his intimate adviser and secretary was quite invaluable for Lister. Lady Lister was the eldest daughter of Mr. Syme and they were married in 1856. She was one of the most beautiful characters one can meet with and she was an ideal wife for Lister. A similar Lister Memorial Fund to this has recently been established in Canada, and the first Lister Memorial Oration was delivered last year by Dr. John Stewart, who was one of those who came with Lister to London in 1877 to help in organising the ward work. In his excellent address I find a few remarks about Lady Lister which I cannot refrain from reproducing here, and I am sure with Dr. Stewart's full approval. I assume that the words which I am going to quote were spoken at the wedding feast in a speech of congratulation to the newly-married couple by Dr. John Brown, author of "Rab and His Friends" among other essays, a well-known, learned, and much-beloved physician in Edinburgh. Dr. John Brown, in his remarks, referred to an illness which Lady Lister had suffered from when a little child and in which she had lain unconscious for several days. He spoke as follows: "Lister is one who, I believe, will go to the very top of his profession, and as for Agnes, she was once in Heaven for three or four days when she was a very little child and she had borne the mark of it ever since." Nothing more beautifully and more truly expressive of Lady Lister's character could be said than that. She was a true helpmate, spending hours with Lister, helping him in his scientific work, and taking notes for him; indeed, the notes of Lister's experiments which he has left behind him are for the most part in Lady Lister's handwriting.

Other Influences.

Apart from the above factors, Lister was much comforted by the approval and interest of men whose opinion he especially valued. In his early days two of his teachers at University College, London, had a great influence on him—viz., Prof. Sharpey, the physiologist, and Prof. Wharton Jones, the professor of ophthalmic surgery, but the man who had the greatest influence on him was Prof. Syme. Lister had the very highest opinion of Syme as a man and as a surgeon, and the fact that Syme approved of and latterly became enthusiastic about his work was an immense gratification and encouragement to him and enabled him to ignore the captious criticisms of his opponents.

And then lastly, and by no means least, he was much encouraged by the enthusiasm of his pupils. I do not know of anyone who excited such enthusiasm and had such influence over his students as Lister had, especially in Glasgow and Edinburgh.

METHODS EMPLOYED AND RESULTS OBTAINED.

I have now mentioned some of the chief influences which helped Lister to undertake and carry to success the battle against sepsis, and having waited long enough now for the case of compound fracture to turn up I may say something by way of example about the methods employed and the results obtained. I think that the way in which he commenced his campaign is most characteristic of his conscientiousness and care in all his work. Most men, I fancy, having arrived at the conclusions to which Lister had come would have been on tenterhooks to try the methods and would very likely have applied them to any case which seemed at all suitable, very possibly with disaster and disillusionment. But Lister had patience to wait till a suitable case for the experiment turned up, and I believe that during that time he was further planning out his campaign and also repeating some of Pasteur's experiments and devising some of his own.

His first case of compound fracture did not come under his care till March, 1865, but no details are given, and all that Lister says about it is that "it proved unsuccessful in consequence, as I now believe, of improper management."

I need not go into the 11 cases which he published in his first paper; the results presented a great contrast to those that he had been obtaining previously.[5] I may, however, mention one or two observations that he made on these early cases which were new to him and of the greatest interest and importance.

---

[4] To change my metaphor for the moment the work of these three men was needed to construct the building properly, and Lister conceived and carried out its erection, Pasteur laid its foundations "well and truly," and Koch assisted very materially by his work on disinfection and also in clarifying the structural details by his first work on infective disease of wounds and no cultivation of bacteria on solid media.

In the first place, these cases gave him a high opinion of the value of carbolic acid for his work; indeed, it is very interesting that this substance, chosen more or less at haphazard, has turned out to be the most useful all-round antiseptic. The cases specially referred to are the second and fifth cases in his first publication. Put shortly, only two of the 11 cases developed phagedænic gangrene, a smaller proportion than usual, but the point that he makes is that in the one (No. 2) the disease developed after he had left off the use of the carbolic acid which he thought had done its work, and in the other (No. 5) it broke out at a small wound which had been overlooked and had not been treated with carbolic acid at all; it had spread from this little wound to the lower part of the bigger wound before it was noticed. In both cases recovery took place, but after a long struggle.

Healing by Blood Clot.

More important was the behaviour of blood clot in aseptic wounds; this was quite new to Lister. He mixed up carbolic acid with the blood and torn tissues and thus left a mass of coagulum and shreds of tissue in the wound, and several points quite new to him were observed. He noticed that the clot did not contract and break down as he was accustomed to see it do but remained firm and adherent to the sides of the wound.

That was the first fact; now for the second. On taking out a piece of the clot after some days and examining it under the microscope, he found that it contained numerous connective-tissue cells, some in bundles; later on blood-vessels began to develop. A third fact was that pieces of dead tissue mixed up with the clot also became infiltrated with these connective-tissue cells, so that not only did organisation occur in the dead clot but also in the more substantial pieces of dead tissue as the result of the penetration of these connective-tissue cells into them and the subsequent disappearance of the dead tissue. This last fact was what chiefly led Lister to take up his work on catgut and ligatures generally. And a fourth fact was that in some cases after two or three weeks one would find the edge of a thin layer of clot on the surface could be lifted up, and on doing so a layer of epithelium was disclosed spreading over the clot just below the surface and completing the process of cicatrisation.

These points constitute the process of healing by blood clot which we have taken advantage of ever since in cases where we could not conveniently bring the edges of the wound together. Curiously enough, this point seems to be lost sight of almost completely at the present time. The other day I picked up copies of four recently published books on general surgery and in only one of them was there any mention of organisation of blood clot. This is a pity, because it is a most useful thing, but for the reasons which I give towards the end of the appendix I doubt if exposed blood clot could be kept aseptic for a sufficient length of time to permit organisation where the technique of the surgeon excludes the use of chemical antiseptics.

Before passing on I may just call attention to the application of his method to an operation wound. As the case is referred to in the appendix I need not go into details here, but I may say that having squeezed out the pus from the abscess (it was a spinal abscess) he mixed it up with the carbolic acid to form a paste with which he dressed the wound. Just imagine the horror of the laboratory bacteriologist at such a suggestion at the present day! Nevertheless, when Lister came to dress the wound next day, prepared to make a paste in the same way as he did the day before, he was astonished to find that there was no more pus and that all that he could squeeze out of the wound was one or two drops of serum! The history of the case is that it remained aseptic and ultimately made a complete recovery.

LISTER'S CLINICAL LECTURES.

I may now pass on to the beginning of the session 1872-73, when I first became acquainted personally with these matters in a curious way that may interest you. I began the actual study of medicine in May, 1871, and devoted myself for the first 18 months to botany, natural history, and chemistry. In October, 1872, when I was in my second year, I took out the classes of surgery, physiology, and anatomy. There was an interval between the classes from 12 to 1 o'clock and I did not know what to do with myself during this interval. My lodgings were a considerable distance away and there was no object in walking there and back; what I wanted was shelter from the biting east winds and the wet. At that time there was no students' club at Edinburgh as there is now, and the only thing I could think of was to go and sit in the general library. But it was small and crowded with students of all faculties and there was no chance of a shy youth like myself getting a seat. So it occurred to me that I might as well take out my hospital ticket in October, 1872, as in the following May, which would be the usual time; in going round the hospital I might learn something, and anyway I would get shelter from the wintry blasts between noon and 1 o'clock.

I shall never forget the first day that I went to the hospital. At 12 o'clock I crossed the road to the infirmary and found crowds of students hurrying along the lobbies, a good many indeed running. I joined the company, full of curiosity, and found that we were going to Lister's clinical lecture. We ultimately reached the large operating theatre and found it filled with men crowding the gallery and standing at the back and in the gangways; there must have been over 200 there, and they were senior men, for the clinical surgery class was not usually attended till the fourth year. I should think that I was the only one of my year there. Presently a man walked into the arena, sat down on a chair placed on the floor of the theatre, and crossing his legs and putting his right hand on his thigh he began his lecture. This man was Lister. He had not spoken many minutes before I became fascinated with the subject and could not help seeing the wonderful era that was dawning for surgery. I had my notebooks for the other classes in my hand and I started to take down what he said, and as he spoke very slowly and clearly and I scribbled very quickly, I was able to take down practically the whole lecture, though, not having learnt any surgery, I did not understand it at all clearly at first. But what a contrast with the lectures on systematic surgery! Very dreary performances, full of curious theories about the reactions of the body and inflammation, quite unintelligible to me, evidently something which had to be memorised but nothing to think about. And then at 12 o'clock, simply seeking shelter from the "cauld blasts o' Auld Reekie," and not knowing that I had met my fate, I became entranced by the wonderful vision laid before us by Lister.

---

[5] As a matter of fact, Lister overrated his first success because at that time he looked on the presence or absence of *putrefaction* as the criterion of failure or success—and most of the cases were free from putrefaction. It was not till later that he adopted *suppuration* as a truer criterion as regards sepsis, for septic diseases might develop in connexion with a wound that was suppurating but the discharge from which was not putrid. The absence of suppuration is a much more useful test of asepsis than the absence of putrefaction. Even the absence of suppuration may theoretically not be an absolutely true guide, for cases of erysipelas occur without suppuration, and it is conceivable that tetanus might do so also. But taken as a whole the presence or absence of suppuration is quite satisfactory as a test of failure or success as regards asepsis. On this criterion I find that five of the 11 cases in Lister's first paper were typically aseptic cases, five were septic, and in one the sepsis seems to have been very slight indeed. Surely that is a very remarkable result for a first attempt in cases where it must always be a matter of doubt whether one has satisfactorily disinfected every recess of the wound or not. I have no hesitation in saying that up to that time Lister had never seen five cases out of 11 running an aseptic course, indeed I doubt if he had ever seen one. As to mortality, of these 11 cases only one died (from perforation of the popliteal artery by a spicule of bone on which it rested, 3½ months after the injury), a mortality of 9 per cent., a very low mortality as cases went at that time.

Is it any wonder that I left the theatre an enthusiast for the profession that I had chosen, and that on lecture days I was one of those who ran? An enthusiast I still remain. On my way home that first afternoon I bought a superior notebook into which, as soon as I got home, I copied out my notes of Lister's lecture and all that I could remember, looking up the words I could not understand in my text-book on surgery. This I continued to do after every lecture, and this notebook, containing Lister's lectures for the winter session 1872–73 and part of the following summer session, I have presented to this College, and it will be found with the Lister relics if anyone cares to look at them.[6]

I always consider that it was a lucky thing for me that there was no students' club at the university in my time, for had it existed I would most probably have gone there for this vacant hour, and possibly learned billiards, but I would not have attracted Lister's notice, and I would not have been delivering this lecture here to-day. These comforts, especially for young people, are not always for the best. I am not at all sure that the youth of the present day do not have things made too comfortable and attractive for them, for this is apt to take away some of the incentive which is very necessary for hard work.

RIVALRY BETWEEN LISTERIANS AND NON-LISTERIANS.

At that time, and till Lister left Edinburgh, the rivalry among the students—between Lister's followers and those who continued the old system—was very marked. The Listerians, who were considerably the more numerous, looked on the non-Listerians as lost souls, Tories of the most die-hard description, and not likely, when they came to practise their profession, to be able to give their patients the best chance possible. The non-Listerians, on the other hand, looked on the others as crazy believers in vain things like germs, rash to a degree, blinded with their enthusiasm, placing their patients in the greatest danger by the outrageous treatment that they proposed, and, as they said that their wounds did not suppurate while those of the other side did, liars of the first water. This rivalry increased for a considerable time, and when I became Lister's house surgeon in Edinburgh in 1876–77 it was probably at its height. It was, I believe, of the greatest value to the cause of asepsis. It made us all extremely careful, because we knew that everything we did was closely watched and no excuses would be accepted if a case went wrong; it would be the principle that would be blamed and not the individual. By this time the antiseptic treatment had reached a stage where we felt that suppuration should not occur in an operation wound made through unbroken skin; if it did occur—and as we were not perfect, one or two cases would suppurate during the six months' session—we all felt it very much; we went about as if everything were lost, ashamed to raise our heads and subjected to merciless chaff. Our only topic of conversation among ourselves on such occasions was how the infection had got in, what was the error in technique which had been committed, and whose fault it was; most excellent training and never forgotten; nothing could make us more careful than to be made to feel that suppuration in an operation wound was due to some error in our technique and was a serious reflection on the surgeon or the dresser. And I do not hesitate to say that I still agree with this axiom, and that in my opinion it holds true at the present time just as much as it did in the old days.[7]

LISTER'S METHODS STUDIED BY DISTINGUISHED FOREIGNERS.

By this time (1872 onwards) Lister's work had attracted more and more attention and quite a number of surgeons began to visit Lister's wards. Curiously enough, very few British surgeons were to be seen, but other countries were well represented, especially Germany. Lister made a special point of showing all his methods and results to the visitors, and as there were constantly fresh arrivals he had to repeat his story frequently; thus his hospital visits were somewhat prolonged. In the early days to which I specially allude the steam spray had not yet been introduced and it was very hard work to keep a hand spray going for any considerable time. The dressing of a patient followed a regular routine, the dresser on duty got on his knees at the side of the bed and as soon as the bandages had been cut he started his hand spray. Lister then lifted off the outer dressing, which was solemnly handed round to each distinguished foreigner to smell. Having satisfied themselves that there was no putrefaction the deeper piece of gauze which was generally placed over the region of the wound was passed round to show that there was no pus, and then in cases where it had not been possible to bring the edges of the wound completely together and where blood-clot could be seen in places between the edges of the incision came the *pièce de résistance*. In such cases Lister usually covered the wound with a piece of material which was impermeable to carbolic acid and which he called "protective," and when this was exposed he would take a pair of forceps and peel off the protective exposing the wound with the adherent organising blood-clot lying in the spaces where the edges had not come together, solid and firm, and with no sign of inflammation or suppuration in the wound. As a rule, this was followed by a sort of gasp of surprise by the distinguished foreigners, and then a violent conversation would break out among them accompanied by equally violent gesticulations so that one became alarmed lest the peace of the nations was going to be endangered. The poor dresser, who was almost, and indeed sometimes actually, faint from the pumping of the spray, was for the time being completely forgotten. But however exhausted he was, and however much his wrist and arm ached, not one of his dressers would give in and let Lister down.

NEW OPERATIONS AND NEW LINES OF TREATMENT.

I have described in the appendix the stage which the methods of treatment had reached by this time, and for some years Lister was probably most interested in revising the operative treatment of every disease or injury that presented itself from the point of view that he need not now fear sepsis in the operation wound. I have also referred in the appendix to the first case of badly united fracture at the ankle-joint which he rectified by open operation, opening the ankle-joint freely. At first he did more bone work than anything else, ununited fractures, badly united fractures, deformities of bone (he was the first to operate for knock-knee, very much on the lines of operation devised by Sir William Macewen some time later), wiring or pegging recent fractures—e.g., fractures of the patella or olecranon, operations for varicose veins, open radical cure of hernia, extensive operations for cancer of the breast, and so on. He was the first to resuscitate suprapubic lithotomy, though this is generally attributed to others. In fact, his remarks on this matter will be found in my notebook, where you will see his reasons for this suggestion, but he was not very happy in their practical application.

---

[6] In his lectures Lister tried to show and discuss examples of as many different surgical diseases (even the simplest) as came to his clinic, so that in the course of the session the students had seen a considerable variety, especially of the ordinary cases which turn up in private practice. In my notebook we find among other things spinal caries, varicocele (with operation), epulis, spina bifida treated by drainage, suprapubic lithotomy (probably the first case performed for many years), excision of elbow, simple fracture, burns, ununited fractures with operation, stricture of œsophagus, stricture of the urethra, malignant tumours of jaw, nævus, hypospadias, cancrum oris, fistula in ano, strangulated hernia, &c.

[7] Not long ago I came across the following very suggestive passage in a paper by Dr. Thomas Keith, one of the great pioneer ovariotomists, on Ovariotomy Before and After Antiseptics (Brit. Med. Jour., October, 1878): "The regulations made in some hospitals that every visitor must sign his name in a book declaring that he has not for a week visited any case of infectious disease or attended a post-mortem examination, before being admitted into the operating-room, has always seemed to me to be meant for a sort of *plaisanterie*. For my own part, when a case goes wrong after an operation, I have seldom to look far beyond myself for the cause of failure—something done, something not done. This is a lesson hard to learn; we blame persons, things, accidents, and circumstances rather than ourselves.

About this time (1873 onwards) Lister's activities followed two great directions, which are both traced out in the appendix. In the first place, he continued his efforts to find fresh antiseptics which might be less irritating and more useful than those which he had hitherto employed, and he spent a great deal of time in testing various substances which were brought to his notice; and the other line of activity which he followed was to reconsider the treatment of all sorts of cases which came before him from the point of view of whether something better might not be done for them by operation than was being done at that time, founded on the knowledge that sepsis might be reckoned to have now been entirely abolished from wounds made by the surgeon through unbroken skin. It was probably in that direction more than in any other that Lister's work became so intensely interesting to the students. They would come to his wards and see treatment employed which had apparently never been heard of, or thought of, by the other surgeons who did not employ antiseptic measures. It would be hopeless to attempt to give any sort of list of the new operations which Lister did, and he himself absolutely declined to publish them.

When I became more intimately associated with Lister I made repeated requests to be allowed to publish notes of his clinic, especially of the new operations and new lines of treatment which he was employing, but although he had done that sort of thing for Mr. Syme, he pointed out, quite correctly, that the matter was very different, and that if such cases as opening joints, complicated operations on bones, and many others that might be mentioned, were published and shown to have much benefited the patients, it might quite well happen that some surgeon who was not a believer in antiseptic treatment, or who was not sufficiently acquainted with the technique, might proceed to perform an operation on similar lines, and being without the protection of antiseptics the patient might lose his life or limb as a consequence. That is the explanation why so little is known of Lister as a surgeon. But, as I said before, I think that it was his fresh outlook on treatment and the interest of speculating what fresh procedure Lister would suggest in a particular case that fascinated the students most. The only sphere of operative work in which he did very little was abdominal surgery. Indeed, with the exception of ovariotomy, which was, curiously enough, supposed to be a very difficult operation and one sacred to a few specially gifted men, comparatively little work had been done in abdominal surgery as we now know it before Lister retired from practice, and he openly stated that he did not feel justified in embarking on surgery in a region with which he was not thoroughly familiar.

Enthusiasm Abroad.—Migration to London.

I became Lister's house surgeon in Edinburgh in October, 1876, having spent the greater part of a year in Vienna and Strasburg, and I may say that in my visit abroad I found the greatest enthusiasm over Lister and his work. Indeed, the fact that I had worked in his wards and was going to be his house surgeon on my return to Scotland was a sort of open sesame, and one of the professors actually asked me to come and show him exactly how Lister dealt with his cases.

It was in the spring of 1877 that Lister received and ultimately accepted an invitation to go to London as professor of clinical surgery at King's College conjointly with Mr. John Wood. The first that I heard of it was one Sunday morning, I think a day or two after he received the invitation, when I was sleeping quietly in the house surgeon's bedroom. I woke up to find someone shaking me, and to my astonishment on opening my eyes I found that it was Lister. He told me about his invitation to London. He had not yet at all made up his mind about it, but he said that if he went he would need to take a small staff with him familiar with his methods and he had come down that morning to know whether if he decided to go I would go with him and again act as his house surgeon for six months at King's College Hospital. Go with Lister to London! I could not believe my ears! Of course I would go with him to London or anywhere else. One would have thought that he was asking me to do him a great favour instead of giving me the chance of a lifetime. In addition he took Dr. John Stewart (now one of the leading surgeons in Canada and held in very great esteem there), Dr. W. H. Dobie, of Chester (in large practice there), and Dr. Altham (who died soon afterwards) as clerks.

Whether Lister was wise in leaving Edinburgh is still open to question, but his decision to go to London was most characteristic of the man. It was merely a question of suffering humanity. His methods and views were spreading very slowly in this country, and after long consideration it seemed to him that they might be sooner adopted if he were in the great centre. But his heart was in Edinburgh where he had everything that he could desire—many devoted friends, delightful society, enthusiastic and large classes, and a large surgical clinique, but where, as he thought, humanity called him he did not hesitate to place the call of duty above the call of pleasure.

He arranged to begin his work there at the beginning of the winter session in October, 1877, and he was asked to give the address at the opening of the winter session. At that time he had become very interested in the question as to whether there were different "species" of bacteria each with its own actions, whether on fermentescible substances or in connexion with diseases, and he looked on this as a very important matter. He had already been working with milk, and he decided to investigate the lactic fermentation of milk, which he did during the summer and autumn of 1877. He satisfied himself by many ingenious experiments that a small bacillus, to which he gave the name of *Bacillus lactis*, was the only cause of the lactic fermentation of milk, and that that was its sole external function in the scheme of Nature. The research was carried out with the precision and thoroughness which characterised all Lister's work. He not unnaturally thought that the absolute demonstration of a specific bacterium, explaining much that was obscure at that time, would be of the highest interest to his audience. Large numbers of the leading surgeons in London and the provinces came to hear this lecture. Perhaps, not unnaturally, they expected to be told about the revolution in surgery which Lister had inaugurated, and instead they had to sit for an hour listening to details of a series of experiments which proved that the lactic fermentation of milk was due to a particular bacterium! The expression on the faces of the audience was very interesting and rather amusing; the majority of the surgeons present could not understand what the lactic fermentation of milk had to do with surgery. Those were the days of the "practical surgeon" as opposed to the "scientific surgeon," the latter being supposed (why I cannot imagine) to have no practical skill or knowledge. It took a considerable time before the "practical surgeon" realised that his day was past.

Lister's Views Unfavourably Received.

When we arrived in London, as far as I can remember, no one at King's College was doing anything specially in the direction of antiseptic work, and, indeed, only a very few surgeons in London. As regards Lister's lectures, the chief thing that struck us at once was the almost entire want of enthusiasm among the students as compared with Edinburgh ; there was no crowd running to get a good seat. Apart from Lister's dressers, only a few students would stroll into the theatre quite casually, apparently taking little interest in the lecture and seldom taking any notes. After the enormous classes in Edinburgh and their great enthusiasm it was very disappointing and depressing. We found after a time that probably the main cause of this was that the examiners in surgery for the various diplomas and degrees were for the most part not favourable to Lister's views, and the students were therefore afraid to attend Lister's lectures in case they should by accident give his views to the examiner. A good many of them, however, planned to stay in town for some time after they qualified so as to see something of Lister's work. This state of matters continued for some time, but gradually died away.

Lister was quite well received by the staff and the students, but the nursing department was very difficult to work with. The hospital was at that time nursed by a sisterhood who looked on the wards as their private rooms, into which no man should come without their permission, nor should he interfere with any of their arrangements such as ventilation, &c. They could always produce a rule of their sisterhood why we should not do this or the other thing which we considered essential for the success of our work. Had we not possessed a keen sense of humour (being more or less of Scottish descent), I do not know how we could have got through, but most of the restrictions were so childish and so evidently invented on the spur of the moment that we could not but laugh at them. I believe the real trouble was that till we appeared on the scene the nurses dressed the wounds, but when Lister arrived he naturally would not allow them to meddle with the dressings ; this solution did not occur to me for some considerable time.

The staff, on the other hand, were quite cordial and interested. Not long after we arrived one of the surgeons was going to amputate a limb, and he asked me to come and look after the antiseptic arrangements. His technique was pretty defective, and he did not seem able to visualise the germs which were ready to seize every opportunity of getting into the wound, so I accidentally from time to time squeezed a quantity of carbolic lotion over his hands, for which I was, of course, very apologetic. He did everything that I suggested till it came to tying the vessels, for which he used silk and left the ends long. I begged him repeatedly to cut them short and told him that they would never separate if the wound remained aseptic, but he was adamant ; he had never seen a case where the ligature could not be pulled out after a few days and he was not going to carry out such stupid advice as to cut them short. The wound healed by first intention except where the bunch of ligatures was, and no suppuration occurred. Day after day I dressed the case for him and he pulled the threads without success. Gradually he began to think that I had told him the truth, and ultimately I got him to pull the threads as far down as he could and cut them off as high up as possible. This he did, and fortunately, as I had taken special pains to keep everything aseptic, no infection took place and that end of the wound was healed in a few days and no further trouble resulted.

Discovery of an Unirritating Antiseptic.

At the time of the migration to London we were still using carbolic gauze, carbolic spray, and carbolic lotions, and although thymol, eucalyptus, and various other antiseptics were tried during the next four or five years no real progress was made in the way of substitution of antiseptics till after the publication of Koch's work on antiseptics. After that Lister took up various mercurial preparations, and a variety of gauzes impregnated with preparations of mercury were employed which had all to be discarded after a time on account of irritation of the skin. Ultimately Lister examined a double cyanide of mercury and zinc and this was found to be unirritating, being insoluble in water. But it was effective as an agent to inhibit the development of bacteria though possibly not to destroy them. It was soluble in the mixture of serum and blood which came from the wound in sufficient amount to render it an unfit soil for the growth of bacteria. This we have used ever since with quite satisfactory results, and I believe that it just fills up the loophole which is left where dressings which are simply sterilised but do not contain any antiseptic are employed. Where a large amount of discharge is expected I generally reinforce the cyanide dressing by a mass of salicylic wool placed outside it. As to these gauzes and wool, it must be remembered that though they contain antiseptics they must be sterilised in the autoclave also, because the antiseptics are not volatile so that bacteria which may lodge in the dressing are not acted on by the antiseptic. The diluted lotions of bichloride of mercury and of biniodide of mercury (1–2000 and 1–4000) were also largely substituted for carbolic acid, the carbolic spray having been given up in 1887.

Lister's Active Work Ended.

Lister's active work in connexion with surgery came to an end about 1893. The death of Lady Lister in the spring of that year, followed soon after by his retirement from the hospital on account of the age-limit, removing at the same time his much-beloved companion and fellow-worker for many years and the opportunity of pursuing his work at the hospital, broke him down and changed entirely the current of his life. But by that time general septic diseases had become practically unknown in his practice in so far as operations through unbroken skin were concerned, and suppuration, even of the mildest type, was an occurrence of extreme rarity, and the possibility of septic complications was quite negligible. He had also reached a point in his technique where the possible irritation caused by the antiseptics employed was not noticeable and did not interfere at all with the healing of the wounds. In 1895 Lister was elected President of the Royal Society, and the work connected with that Society gave him another five years of life. But after that, although honours continued to be showered upon him, the great brain became tired, his memory failed, and he began to long for the time to come when, as he firmly believed, he would meet his wife and his friends again and commence a new life.

The late Dr. A. Christy Wilson.—Alexander Christy Wilson, M.D. Edin., the oldest medical practitioner in Doncaster, died on April 27th, in his eightieth year, after an illness of several months' duration. A native of Hawick, he studied at the University of Edinburgh, where he graduated M.B. and C.M. in 1867, having previously in 1866 obtained the L.R.C.S. Edin. While at the University he was a President of the Royal Medical Society of Edinburgh. In 1870 he took the degree of M.D., having in the meantime visited the hospitals in Paris. Settling in Doncaster 55 years ago, he soon established himself in the town. For over 40 years Dr. Wilson was an honorary surgeon at the Doncaster Royal Infirmary, and on his retirement from active surgical duty he became its senior consulting surgeon. He was a past President of the Yorkshire branch of the British Medical Association, and also of the Leeds and West Riding Medico-Chirurgical Society. Dr. Wilson took an active part in all philanthropic movements in the town, and was a warden of St. James's Church. In August, 1923, Dr. and Mrs. Wilson celebrated their golden wedding, and Mrs. Wilson survives her husband. Two sons are in the medical profession. Dr. Wilson contributed papers on abdominal surgery to *The Lancet* and the *British Medical Journal*.

Croonian Lectures

ON THE

RÔLE OF FATS IN VITAL PHENOMENA.

By J. B. LEATHES, F.R.C.P. Lond., F.R.S.,
PROFESSOR OF PHYSIOLOGY, UNIVERSITY OF SHEFFIELD.

LECTURE IV.*

In the first of these lectures an attempt was made to review the ideas that are current with regard to the part played by fats in the structure and life of cells. Confusion, conflict, and nothing but what was unsatisfactory could be found in them. Then certain facts were described of which as yet cytologists have made little use. Some of these facts are capable of being much more clearly defined than they yet are, but are then, it was suggested, likely to contribute something, possibly much, to the formation of clearer ideas. Briefly the facts are these. Simple fats, triglycerides, have some 50 paraffin carbon atoms, arranged in three parallel rows, for six to which some hydrophile properties have to be assigned. It is these latter that enable fats to form films on water which paraffins cannot. Lecithine, with perhaps 34 paraffin carbon atoms, in two rows, attached to a much larger hydrophile group, presents in this group, in addition to the glyceryl ester arrangement of the simple fat, a free phosphoric acid hydroxyl and a free basic hydroxyl in choline. It has thus 30 per cent. less of the paraffin and an incalculably greater hydrophile component. It is still insoluble in water, but in contact with water behaves totally differently from simple fats, in such a way that ideal equilibrium would appear to be unattainable until the lecithine molecules were arranged in films two molecules thick with the hydrophile groups facing the water on each surface. Against the attainment of such an ideal equilibrium many intercurrent tendencies must operate; the presence of other substances in the aqueous phase, as well as the admixture of other lipines and of cholesterol with the lecithine, is bound to introduce complications. Indications indeed of the influence of cholesterol have been obtained already in what makes no claim to being more than a tentative exploration of the subject. Many attempts, which have not been referred to, have been made to pick up clues as to the influence of other substances in both phases, but many more remain to be made. Nor can it be claimed that as yet any serious call on technical ingenuity has been made in the pursuit of the inquiry. An attractive prospectus could be composed.

At any rate we cannot be satisfied merely with the two ideas as to the state of fat in cells, which are all that is usually offered, an emulsion of oil in water, with possibly an aggregation of fat at the cell surface. With these alone no sense can be made of the diphasic cell systems. It would be blasphemy to suppose that it could. Such complacent irreverence in the contemplation of the supreme mystery of the structure of living protoplasm would be unphysiological, unscientific.

Is There Structure in Protoplasm?

In what sense is it possible to speak of structure in protoplasm? Much of what used to pass as evidence for such structure has been shown, notably by Hardy, to be fallacious. The fixatives used in histology produce similar appearances in colloidal solutions of mere common proteins. The intriguing networks and fibrils have gone; the Nissl granules have melted away. Were it not for the solid work in the micro-dissections of American cytologists, Barber, Kite, Chambers,[1] and others, who knows whether our faith in the reality of mitotic figures or even the nucleus were not in danger?

Liquidity of Protoplasm.

Protoplasm is liquid. Reaffirmation of this fact, which has sometimes been lost sight of, is now rightly held to be necessary. Much of the evidence on which it rests has long been available, much more has come to light in modern investigations. By exposing cells, especially egg cells, to centrifugal action Lyon (1907)[2] showed that their contents take up new positions, determined apparently solely by exaggeration of the force of gravity. Oil globules appear confined to one end; pigment granules and other inclusions congregate at the other; between the two is a clear hyaline zone, in which the nucleus lies near the oil globules, while at the edge of the opposite granular zone the smallest of the granules can be seen in active Brownian movement. Brownian movement, it is well known, is frequently observed in cell protoplasm, including that of nerve cells (Marinesco[3]). It stops when the cell dies, but also at other times during the normal life of the cell. In addition to the evidence from Brownian movement there is that which can be derived from the observations of streaming movements in protoplasm, some of which date back to the days of Corti and Treviranus. Among the most striking of these observations are still those of Arthur Lister[4] (1888) on the rhythmically reversed flow of granules in the protoplasm of mycetozoal syncytia, for some seconds first in one direction, then slowing down, stopping, and starting again in the other, and so repeated indefinitely. Such syncytia, too, he observed as he made them creep through a cotton-wool filter in which the ingested vegetable spores were found to have been strained off as the organism emerged clear as water on the other side. What kind of structure can such protoplasm have? Similar to these are the descriptions of streaming movements in the pseudopodia of amœbæ, towards the apex of the pseudopod in its axis, in the opposite direction on its surface; these movements Chambers (1920) was able to modify by injecting fluids into the cell; he speaks of them as "depending upon a delicate balance of liquefying and solidifying tendencies in its protoplasm." Currents have been described also in the dividing egg, in nerve cells, in epithelium, and in cells of the pancreas; in fact, new observations of this phenomenon are continually being added to the old ones. That protoplasm is liquid is again argued from the fact that included drops of liquid are not prevented by any rigid structure of the surrounding protoplasm from taking up the spherical shape that would be given to them by their own surface-tension. Carlson,[5] too, measured the time taken for an impulse to travel in a certain nerve of the slug, when the animal's body was contracted and when it was extended. The result showed that the nerve elongates and does not merely uncoil itself as the animal is elongated. The consistency of the nerve fibre must be much more fluid than probably had been commonly supposed.

Viscosity of Cell Substance.

But if protoplasm is liquid how can it have structure? Going back again to the earliest descriptions of cell substance, it is familiar that it was spoken of as a sticky, viscous fluid. In modern investigations the viscosity of protoplasm has received much attention. Cell protoplasm will adhere to a micro-dissection needle and can be drawn out in a long strand, which may become detached from the cell, or if released is retracted. In either case the original appearance of the cell may be restored. An amœboid cell may adhere to the surface over which it is moving, so that portions become detached and are left behind as the cell moves on. Some cells like the motor nerve cells in the frog are so tough that it is difficult to dissect them at all; others like those of the pancreas break up if merely pricked. The viscosity of cell substance is known to vary significantly at different times in the life of the cell. These variations have been studied by the effect of centrifugal action. The viscosity of the egg protoplasm has thus been shown to be increased after fertilisation (Heilbrunn,[6] Odquist[7]). If an egg of which the contents have been stratified by centrifugal force is then fertilised, no Brownian movement is observed till shortly before division, when it starts at the region where a few seconds later the cleavage furrow begins to appear. By micro-dissection these viscosity changes in the recently fertilised egg have been studied in greater detail. It is high in the radially marked cytoplasm round the clear centrosphere, high when the chromosomes are arranged about the equator; but when they have separated and the amphiaster is formed the viscosity of the equatorial region is low, and a needle can move about in it much more freely than in the cytoplasm elsewhere. In some cells the cytoplasm can be stripped off the spindle and the bare spindle retain its shape. But with two needles it can be stretched, the chromosomes stretching with it, the whole when released returning to the original shape. In some cases the disposition of the parts of a mitotic cell can be visibly changed by mechanical disturbance, the rays of an aster deflected or even made to disappear, and then when left to themselves they may reform, recover themselves, and division proceed apparently normally; as though protoplasm were not only viscous, but elastic in its viscosity because its viscosity depends on a persistent tendency in its components to arrange themselves in it according to an ordered plan. In other cases mechanical disturbance of one part of a cell may result in disintegration that spreads sometimes rapidly to other parts, the integrity of the whole being dependent upon the integrity of the part.

---

* Lectures I., II., and III. appeared in The Lancet of April 18th and 25th and May 9th respectively.

Bayliss[8] described the cessation of Brownian movement of ultra-microscopic particles in the pseudopodia of amœbæ as a result of brief weak electrical stimulation, and how under favourable conditions the effect would pass off and the movement begin again. Such disturbances as are called stimuli may therefore bring about visible changes in viscosity.

Cause of Viscosity of Cell Substance.

The viscosity of cell substance is commonly ascribed to the proteins that it contains. Some colloidal solutions, those of metals or their sulphides for instance, are hardly more viscous than pure water. Considerable amounts of finely divided solids may be suspended in water without its becoming viscous. But while a solution of egg albumin containing 13 per cent., about the amount in white of egg, has double the viscosity of water, one of little more than double that strength is ten times as viscous as water. Other proteins that have been investigated give much more viscous solutions than egg albumin, euglobulin in 13 per cent. solution, for instance, has a viscosity nearly 30 times as great as water, and sodium caseinogenate in still lower concentration the same (H. Chick, 1914).[9]

From facts such as these it is argued that the colloidal particles in a protein solution are not solid. That they are not solid as particles of gold are must be granted, if it is felt necessary to prove that. But when the argument proceeds thus: emulsions, suspensions, that is, of spherical liquid drops in an immiscible liquid, have in certain conditions a high viscosity; therefore the high viscosity of protein solutions must be accounted for similarly; and the particles of protein, since they are not solid as metals are, must be liquid, immiscible with water, and by implication spherical drops, are we bound to follow this argument step by step and accept it all as logically necessary? It must be admitted it is not customary to set the argument out as categorically as this. All that is usually done is to call colloidal solutions such as those of proteins "emulsoid," and leave it at that. An emulsion is something we can understand; a system of two immiscible liquids, one suspended as spherical drops dispersed through the other; where one liquid begins the other ends, and there is a definite interface between the two at which substances dissolved in either may tend to accumulate. What is an emulsoid solution? It is very well to say that the particles of the solute contain some of the liquid, and the surrounding liquid some of the solute in true solution, but in what sense is such a system like an emulsion? Are there two liquids? Is one of them dispersed in spherical drops? Where one begins does the other end? Can we say there is an interface between the two and that all that would follow from that is to be implied? No indication is given as to whether the answer to these questions is affirmative or negative. I venture to think it should in each case be negative. If so, in what sense are such solutions like emulsions? The term emulsoid is merely suggestively misleading; it is not happy; in scientific terminology words ending in "oid" seldom are.

Structure of Protein Molecule.

In endeavouring to understand the viscosity of protein solutions and its bearing on the structure of protoplasm it may be well to think of the stereochemical configuration of a protein molecule. Such a molecule is a chain of amino-acids; in this chain each amino-acid must tend to be set at a certain angle to the one next to it, the angle being determined by the directional forces between the atoms concerned in the linkage, and also probably by attractions and repulsions between neighbouring polar groups. The whole molecule will thus tend to assume, if free to do so, a certain disposition in space of a very complex sinuous pattern. It must be remembered that what are called "straight" chains of carbon atoms in chemistry are certainly not straight; and that the number of amino-acid chains in a gelatin molecule is more than 100, in hæmoglobin nearer 200, containing many ring formations as well as "straight" chains. This pattern, when the protein is in the dry state, cannot be preserved; the molecules are crumpled up and unfold only in solution, if, indeed, having once been dried they can again be disentangled. Dry gelatin expanding in very dilute hydrochloric acid may take up 70 times its weight of water (D. Jordan Lloyd).[10] A coherent gel may be obtained from a solution of gelatin on cooling to 8° C. when the gelatin is only 0·2 per cent., when, that is, the space occupied by the water in the jelly is 500 times as great as that actually occupied by the gelatin (Rohloff and Shinjo).[11] In a gel formed on cooling a solution the gelatin molecules clearly must link up to each other so as to form a complicated meshwork in three dimensions, in which the communicating interstices filled by water far exceed in volume the space actually occupied by the gelatin molecule. This linking of gelatin molecules is, however, not strong enough to stand more than a certain intensity of kinetic activity in the permeating liquid. As this activity increases with rising temperature the linkages are loosened, not everywhere at once, but gradually. At the same time the initial high viscosity diminishes, at first rapidly, then more slowly, till the molecules are not allowed to remain linked up at all. Arisz[12] measured in a 10 per cent. solution of gelatin, which solidified at 44° C., a viscosity at 46° 50 times, at 47° 42 times, at 55° four times, and at 65° twice as great as that of water. The viscosity is a measure of the effective operation of forces that tend to link the molecules together, their stickiness. Something similar seems to be implied in the conception of any emulsoid colloidal solution of a protein with its comparatively high viscosity; the aggregates of protein molecules must arise from the tendency of molecules to cohere, and the aggregates tend to be linked together by the free molecules dissolved in the surrounding fluid, sufficiently at least to diminish the fluidity of the system.

The viscosity of the cell substance may be accounted for in the same way. Indeed, the fact that liquid protoplasm can enclose spherical drops or vacuoles, if it proves that protoplasm has not the rigidity to prevent the shape of the drops being determined by their surface tension, mark the word, and therefore that protoplasm is liquid, proves no less surely that there must be cohesion between the molecules and aggregates of molecules composing the colloidal protoplasmic solution, sufficient to prevent these molecules from being scattered by the kinetic activity of the water molecules among which they float, sufficient, too, to set a limit to the amount of water which they can enclose. Protoplasm is not miscible with water till it disintegrates, because, though liquid, it has structure.

CELL PROTEINS UNOBTAINABLE.

In some of the earliest descriptions of cell protoplasm it was spoken of as a jelly; more recent studies, including those referred to above, lead to the idea of a viscous fluid, the viscosity of which can vary. In any case it would be a mistake to argue from what is known of the behaviour of one kind of protein as to the behaviour of another. No cell protein has been studied as casein, gelatin, egg albumin, or the serum proteins have. Cell proteins cannot be obtained. But the proteins that have been studied behave so differently from each other that it is impossible to predict which of them, if any, a particular cell protein will resemble. They are alike only, it may perhaps be safe to say, in that when in solution they give colloidal solutions which in certain circumstances and concentrations have high viscosity.

If the way in which I picture protein molecules in protoplasm is justifiable, as floated out in the water of the cell, cell proteins may well be thought of as unobtainable. They are put together, they grow, where they live, expanded as the floating vegetation of the sea; expanded and yet not always necessarily to the same degree; for the disposition of the parts of the pattern must be capable of change according to whether the polar points are unrestrictedly free to act on each other, or are engaged by foreign molecules or ions that come their way. A globulin is insoluble, does not expand, except when certain ions are available. The idea of attempting to collect the proteins from some millions of cells without change may be as unpractical as it would be to collect a handful of gossamer webs in order to study the way in which they were put together. It is impossible to dispute the evidence for structure in protoplasm, while at the same time it is impossible to deny it at all times fluidity. Structure in liquids must appear as one of those incomprehensibles of which the great physician exhorted us to have a glimpse, " things that thought doth but tenderly touch "; but it is not merely an idea, it is a reality that must be apprehended. Liquid crystals are formed not only by derivatives of cholesterol, but also by many substances of known chemical constitution, azoxyanisol, ethyl azoxybenzoate, esters of p.-azoxycinnamic acid, and many others; and the viscosity of some of the melted substances has been measured in the isotropic condition and found to change as the crystals form.

THE PERMEABILITY OF CELLS.

The question, then, is how far will such ideas of protein solutions as we can form serve to account for the properties of protoplasm. The aggregates of molecules that constitute the colloidal particles in protein solutions are, it is commonly agreed, like sponges, full of water. Most cells, but not all, are in most circumstances permeable to water: the cells that line the stomach are not, at least water is not absorbed there as it is beyond the pylorus, cutaneous epithelium cells let no water through, nor do the cells that line the bladder and ureter, neither when the osmotic pressure of the urine is one quarter nor when it is four times as great as that of the blood; and however it may be with keratinous squamous epithelium, the surface cells of transitional epithelium are clearly living nucleated cells composed of protoplasm. According to Hamburger[13] even some few red blood corpuscles are found intact after diluting blood with much water; and when treated with cobra venom this property becomes general. Lillie describes sea-urchin eggs impermeable to distilled water until traces of calcium are added. In general, however, it may be said that protoplasm, even its surface layers, are permeable to water; Heilbrunn[6] has shown that as a cell swells in hypotonic solution the viscosity of the protoplasm diminishes, as it shrinks in a hypertonic one the viscosity increases. Disregarding, therefore, for the moment exceptional cases, important though they may be, the general permeability of cells to water is what might be expected if they were composed merely of colloidal proteins. But in the known properties of common proteins there is little to warrant our ascribing to the proteins that protoplasm contains, and to them alone, all the phenomena of impermeability to other substances than water which it manifests, unless it be in the case of substances in colloidal solution. Fibrin clot and casein curd cannot even hold back the proteins of serum and whey. A jelly of gelatin, though unlike these it is impermeable to colloids, has since the days of Graham been known to allow rapid diffusion of salts, and when used in ultra-filtration lets, as far as is known, everything but colloids through. Gels are permeable to common salts: that does not mean, of course, that they offer no obstacle at all to their passage. The very viscosity of mere solutions of proteins shows that in such solutions the freedom of movement of even water molecules is impaired. The greater the concentration of the gelatin in a jelly the more this freedom is restricted. It is practically impossible to disentangle the last traces even of water from gelatin. The freedom of movement of molecules of salts must be still more restricted. It is known that the diffusion of salts in concentrated gelatin jellies is considerably impeded, and that of different salts in different degrees—e.g., sulphates more than chlorides. The salting out of proteins is most easily understood in this way. The water can get free from the meshes of the protein molecules more easily than the salts can diffuse in, the more so the more the expanded protein molecules contract as the water escapes. The enormous pressures necessary in ultra-filtration through gelatin filters also bear witness to the obstruction that protein molecules when closely packed offer to the movement of salts. But it is quite another matter to ascribe all the semi-permeability of the cell to such protein structures as the dimensions of cells allow. If a jelly permits the diffusion of salts we have no right to suppose that the molecular aggregates in the viscous colloidal solution of gelatin or other protein do not.

But there is no characteristic of cell protoplasm that is more fundamental, none more essential to the performance of its functions, than selective semipermeability capable of variation. When we understand how this is brought about, in all the degrees in which it can in different conditions be observed, there will be no mystery in secretion, nor in absorption, probably none in the activities of muscles and of nerve cells.

Nor can we escape by supposing this semipermeability to be the property only of a mysterious surface layer, while the rest of the cell behaves as if merely a colloidal protein solution. It is true that Chambers has in his fascinating work carried out the delicate operation of injecting solutions into starfish eggs through pipettes with a bore of less than 1μ, and seen that the salts ammonium chloride and sodium carbonate diffuse uniformly through the protoplasm stained with neutral red; whereas if the eggs are merely suspended in solutions of these salts the NH_4 or CO_3 ions pass in through the surface layer but not the Cl or Na ions. In this egg, therefore, this semipermeability is the function of the surface film. But the physiology of cells is not all of it exemplified in a resting egg cell. The cell that secretes, the cell that absorbs, must have protoplasm that is discontinuous. In it there must be delimited regions bounded by surfaces, here at one moment, somewhere else the next, impermeable where but now they were permeable. It is not possible to reconcile physiological functions with a conception that admits semipermeability only at the superficies of the cell.

Semipermeability is the corner-stone in the structure of protoplasm. It is hard to see how anything that is known of the properties of proteins can enable them to provide for this. Loosely put together of heterogeneous atomic groupings, loaded up with water as they are, nothing but faith in the miraculous virtues of the unknown can have made us ascribe to them alone all that is puzzling in the edifice of the cell. If what is known is to count for anything, is it not at least possible that the paraffin chains of fatty acids and their derivatives may help us out? Some sort of partitions there must be; films that spread across the interstices of the labile spongy protein framework. Even were the protein coagulated, shrunken and set, this seems to be no less necessary.

Interfacial Phenomena and Cellular Physiology.

In attempts to fashion cytological conceptions on lines that are familiar in physical chemistry much has been made of the significance of surfaces in cells, not only the surface presented by the cell to its environment but also the surface of the protein aggregates in the colloidal solution constituting its substance. As the cell membrane has been supposed to be formed by adsorption at an imaginary interface between water inside and water outside the cell, so, too, an imaginary interface between the water permeating the "emulsoid" aggregates and that in which they float has been supposed equally to be the seat of adsorption. The aggregates are supposed to be mainly protein with relatively little water in their composition, the surrounding liquid water with relatively little protein in it, and that little in true solution. In an emulsion there is a true interface between immiscible liquids. Is it not possible that the pernicious suggestiveness of a term has deceived us? Can there be interfaces in the true sense of the word in an "emulsoid," where there is no question of immiscible liquids; where the liquid is the same throughout, and the non-aqueous phase, a solid, but solid something as an expanded seaweed floating in the sea is solid. Where is the interface? The many chemically polar points in protein molecules, by reason of which these molecules tend to adhere to one another, may serve, no doubt, to hold molecules or ions of other kinds as well; but if so the forces that determine the fixed positions of these foreign molecules and ions are not those understood to operate in adsorption. It is not a simple case of the Gibbs Thompson law. Fats are truly immiscible with water. Where oil begins water ends and there is a true interface. A monomolecular film of fat or lecithine coheres by virtue of the affinities of paraffin chains for each other, with which water has nothing to do. These chains are known to cohere. Straight, smooth, and homogeneous, they may be expected to fit closely and present, at least so far as they are saturated chains, no points to which foreign molecules or ions can attach themselves so as to weaken that cohesion.

If in order to understand the physiology of cells it is necessary to take into account interfacial phenomena, it is fats rather than proteins that we must look to to provide the interfaces. Surface phenomena, surface tension, and the formation of surface membranes presuppose a boundary at which the liquid water ceases: the presence of protein molecules, floated out in the water and containing many times their weight of water, sets no such boundary, even though the freedom of movement of water among the floating fabric of these molecules is somewhat restricted. When it is said that protoplasm is immiscible with water, the only way in which the proteins that it contains can account for this property in it is if the spreading protein molecules tend to join up, so as not to be scattered by the kinetic activity of the water within and without the region through which they are spread out. It is true that other colloidal ions to which the protein molecular meshwork is impermeable may give rise to unequal distribution of electric charges, because of the permeability of the same meshwork to smaller ions with a charge of opposite sign. But no one has yet succeeded in making it clear how any fundamental physiological functions in cells can be elucidated by this fact.

Whichever way we turn, therefore, we find that what is known of proteins points to the impossibility of accounting for the properties of the cell substance by their aid alone. Whichever way we turn there are indications that what is known and what it is possible to learn of the properties of fat must be of service. The rôle of fats in vital phenomena is a subject on which it may be expected that much may turn that is of importance to physiologists and to physicians.

CARBOHYDRATE TOLERANCE IN PREGNANCY.*

By H. F. HÖST.

(From the University Obstetric and Gynæcological Clinic, Oslo, Norway: Prof. Kr. Brandt.)

As early as the middle of last century Blot[1] called attention to the relatively frequent occurrence of glycosuria in pregnancy, but not until about the beginning of the present one was its influence on carbohydrate metabolism accurately studied, when v. Jaksch,[2] Hofbauer,[3,4] Lanz[5] and others showed that glycosuria could often be produced in pregnant women who were not spontaneously excreting sugar by increasing the amount of carbohydrate taken.

Pathogenesis of Experimental Glycosuria of Pregnancy.

The pathogenesis of this pregnancy glycosuria was assumed to be the same as that of diabetes mellitus. Thus Cristalli[6] asserted that it was due to a functional weakening of the liver by pregnancy, a view which was adopted by Hofbauer[3,4] in Germany.

The introduction of practical clinical blood-sugar estimation methods in the beginning of the present century rendered possible a more accurate study of the relation between the sugar in the blood and urine, and it was found that while diabetic glycosuria was always due to hyperglycæmia, excretion of sugar in pregnancy could often be demonstrated in association with normal or slightly augmented blood-sugar (Novak, Porges and Strisower,[7] and Jacobsen[8]). Glycosuria occurring spontaneously in pregnancy was, in the light of these investigations, classed with "renal diabetes" which Klemperer[9] had already described in the 'nineties. The numerous investigations of later years seem to show that the experimental

---

* The investigation was carried out with the aid of a grant from "A/S Freia Chocoladefabriks medicinske Fond."

glycosuria of pregnancy is also caused by increased permeability of the kidneys, the so-called renal threshold, but all do not at present share the same opinion, for Dietrich,[10] for example, recently maintained that it was the result of an abnormally high blood-sugar rise—a "morbid depression of the power of assimilation."

Frequency of Experimental Glycosuria of Pregnancy.

Just as opinion is divided with respect to the pathogenesis of the experimental glycosuria of pregnancy, so also do views differ as to its frequency. A few authors like Frank and Nothmann,[11] Wetz and van Netz,[12] and Bauer,[13] state that glycosuria following an excess of carbohydrate can be constantly produced in the first three months of pregnancy, and therefore recommend a tolerance test as a certain diagnostic sign of pregnancy. Others, on the contrary, such as Seitz and Jess,[14] only detected glycosuria in half the cases examined, and deny the value of the test from a diagnostic point of view.

Concerning the actual cause of the glycosuria of pregnancy there are only the investigations of Küstner,[15] who concludes from them that the sugar excretion is of renal origin, and due to a function of the corpus luteum. In women, carbohydrate tolerance—measured by the blood-sugar rise following the administration test—and the position of the renal threshold have been studied very little, most of those who have undertaken these investigations having worked with men. However, we should expect, a priori, that, just as in men, individuals can be found with a low renal threshold and a relatively high blood-sugar rise after administration of carbohydrate with consequent glycosuria. Before judging the effect of pregnancy therefore, we must first clear up the questions of the tolerance and threshold in non-gravid women.

Experimental Results.

The work to be recorded here was carried out during 1923 in the Gynæcological Clinic. For permission to do it, as well as for kindness and help during the work, I am much indebted to Prof. Brandt. The object of the experiments was to discover how often glycosuria can be produced in pregnancy, whether the glycosuria is a result of a low renal threshold or is due to a big blood-sugar rise, and lastly whether any cause for the low threshold or the marked hyperglycæmia which provokes the sugar excretion can be found.

All the persons investigated received 50 g. chemically pure glucose dissolved in 200 c.cm. water in the morning on a fasting stomach. Blood-sugar analyses were made beforehand and every 15 minutes for two hours after the administration of the sugar solution, while the urine was examined every half hour. The blood-sugar determinations were done by Hagedorn and Norman Jensen's method,[16] and the urine was tested for sugar by means of Benedict's reaction. In a number of cases the calcium content of the blood serum was estimated by Kramer and Tisdale's [17] method.

As will be seen from Table I., 19 non-gravid women were investigated. These women were not absolutely normal, but had more or less trifling complaints such as dysmenorrhœa, displacements of the uterus, &c., which could hardly be accused of affecting the carbohydrate metabolism. Five of the 19 non-pregnant women got glycosuria. In two the glycosuria occurred with a maximal blood-sugar rise of between 150 and 200 mg. per 100 c.cm. blood, while in the other three the glycæmia was above 200 mg. None excreted sugar with a blood-sugar rise of less than 150 mg.; in other words, there were none amongst the 19 with a low renal threshold. In two of the women who did not excrete any sugar the blood-sugar rose above 200 mg. These two thus had higher renal thresholds than we generally find. As will be seen, no less than five of the 19 had hyperglycæmia in excess of 200, which seems to show that relatively high blood-sugar rises are rather common in women.

TABLE I.

Nineteen Non-gravid Women.

Glycosuria in 5—	Max. hyperglycæmia :—
	Less than 150 in none.
	Between 150 and 200 in 2.
	More than 200 in 3.
No glycosuria in 14—	Less than 150 in 4.
	Between 150 and 200 in 8.
	More than 200 in 2.

Altogether 39 pregnant women were examined in whom glycosuria had not been previously demonstrated. Thirteen of them were in the first three months of pregnancy, and the remaining 26 were in the fourth to ninth months. (Table II.) Eight of the 13 got glycosuria while five were free, and of the 26 whose pregnancy was more than three months advanced, ten had glycosuria, but there was no excretion of sugar in 16. The number of persons investigated is too small to form the basis of accurate statistics, but the experiments indicate that glycosuria can be provoked in about 50 per cent. of all pregnant women, and therefore rather more often in pregnant than in non-pregnant women, and that it can be produced more frequently early in pregnancy than in the later months.

TABLE II.

Thirteen Women, Pregnant in the First Three Months.

Glycosuria in 8—	Max. hyperglycæmia :—
	Less than 150 in none.
	Between 150 and 200 in 1.
	More than 200 in 7.
No glycosuria in 5—	Less than 150 in 1.
	Between 150 and 200 in 4.
	More than 200 in none.

Twenty-six Women, Pregnant in the Last Six Months.

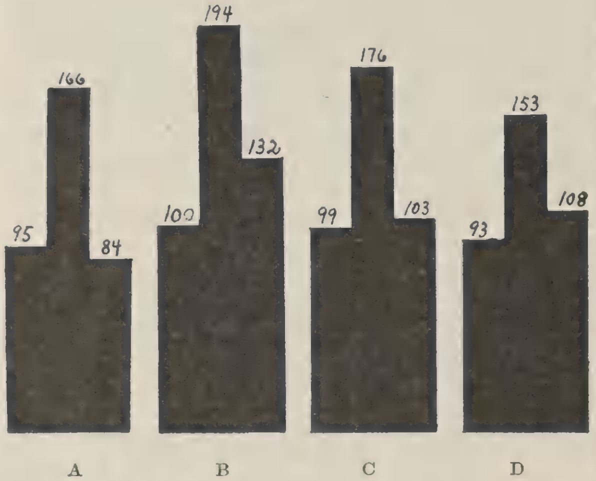
Glycosuria in 10—	Max. hyperglycæmia :—
	Less than 150 in 5.
	Between 150 and 200 in 5.
	More than 200 in none.
No glycosuria in 16—	Less than 150 in 9.
	Between 150 and 200 in 7.
	More than 200 in none.

On inquiring into the relation of glycosuria to glycæmia it will be seen that in the first three months no fewer than seven of the eight women who got glycosuria had blood-sugar rises above 200 mg., while one had hyperglycæmia between 150 and 200. In the women who were past the third month of pregnancy the conditions were different, since five who got glycosuria had blood-sugar rises less than 150 mg. and the other five between 150 and 200 mg., while none had more than 200 mg. Glycosuria therefore has usually a different pathogenesis in the first and second periods of pregnancy. In the first months there is a sharp blood-sugar rise which causes glycosuria, while the position of the threshold does not deviate from the normal, so that there is no renal glycosuria. In the latter part of pregnancy, however, glycosuria is, as a rule, due to a low renal threshold, while the blood-sugar rise is often remarkably small, and thus glycosuria in this stage of pregnancy can rightly be classed as renal.

As will be seen, in addition to the characteristic difference in the situation of the renal threshold there appears also to be a distinction in the blood-sugar rise—that is to say, in the carbohydrate tolerance in the first months and later in pregnancy, and a further investigation of tolerance is therefore of interest. The best measure of carbohydrate tolerance is a determination of the area of the blood-sugar curve after a large dose of glucose, as proposed by Hagedorn.[18] This calculation, however, is laborious, and in my opinion almost as good an indication of tolerance can be obtained merely from the maximal blood-sugar rise and the blood-sugar concentration two hours after the sugar solution is taken. By calculating the mean value of these concentrations and of the glycæmia before the experiment in non-pregnant cases in the first three months and in the last six months of pregnancy, the values can be graphically expressed as in Fig. 1.

In 19 non-pregnant women the *mean* blood-sugar concentration before the experiment was 99 mg., the maximal concentration 176, and after two hours 103 mg. In 15 women in the first three months of pregnancy the same values were 100, 194, and 132 respectively, and in 28 women in the last six months the figures were 93, 153, and 108. For the sake of comparison the result of the same tolerance test in 25 healthy men is recorded, whom I had previously investigated and whose values agree rather well with those of the non-pregnant women. It will be observed that the average blood-sugar rise in the first three months of pregnancy is considerably higher and lasts longer than in the non-pregnant, while at a later stage of pregnancy it is less than in the non-pregnant and much less than in women in the first three months of pregnancy. The number examined was so large that the result cannot be due to chance but must indicate a causal relation, which proves that in the first months of pregnancy there is, as a rule, a more or less pronounced hypofunction of carbohydrate metabolism, while in the latter part the opposite is often the case—that is to say, there is a marked capacity for rapidly metabolising large quantities of carbohydrate. If the several blood-sugar curves are studied, which space does not allow, the difference referred to will be still more striking, for it will be observed that some of the women in the early stages of pregnancy have blood-sugar curves which are typical of diabetes, while many in the later months only get a very small blood-sugar rise.

FIG. 1.



Carbohydrate tolerance in various classes. A, 25 healthy men; B, 15 women pregnant one to three months; C, 19 non-pregnant women; D, 28 women pregnant four to nine months.

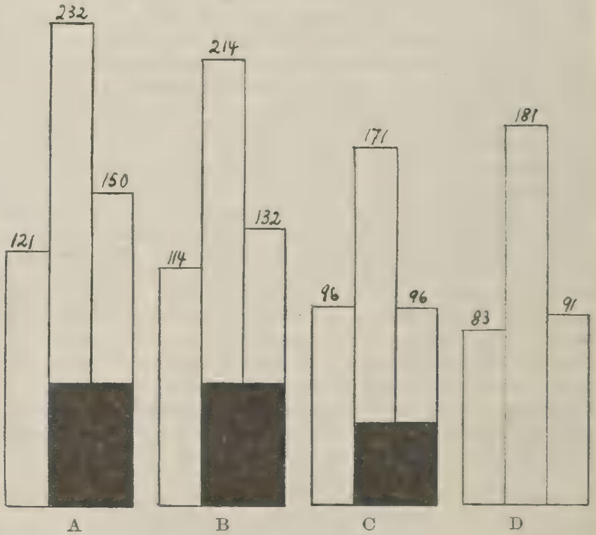
The tolerance test was done in a patient of 42, who suffered from repeated abortions, before and after two operations. The first two tests were made when the patient was two and a half months pregnant. As will be seen from Fig. 2 large blood-sugar rises occurred on May 18th and 21st, greatest in the first test, and also marked glycosuria, indicated by the black square at the foot of the columns. A few days later sterilisation by laparotomy was performed, and at the same time a corpus luteum of the right ovary was extirpated. The next tolerance test was done 12 days after the operation. There was a considerably smaller and shorter blood-sugar rise and slight but undoubted glycosuria. On June 2nd the uterus was evacuated, and on June 13th the fourth test was carried out. This showed a higher blood-sugar rise than the third test, but in spite of this there was no glycosuria. We can hardly conclude anything from these experiments on a single patient, because hyperglycæmia can vary greatly in uniform experiments in the same person, and, moreover, its maximum can only be approximately determined when blood samples are not taken more often than every 15 minutes. But if the experiments on this patient are taken in conjunction with those previously referred to, which show that the blood-sugar concentration after a tolerance test usually rises considerably higher in the first three months than later on in pregnancy when the corpus luteum is undergoing involution; and when it is remembered that the renal glycosuria often found in the later months of pregnancy disappears immediately after delivery, the experiments on this patient indicate that the corpus luteum of pregnancy depresses the carbohydrate tolerance measured by the height and duration of the blood-sugar rise and that the fœtus or placenta causes the low renal threshold which is characteristic of the later months of pregnancy.

In 12 non-pregnant cases 17 tolerance tests were done before, during, and after menstruation, to decide the question whether the corpus luteum of menstruation affects tolerance and the threshold as Küstner believes he has shown. The blood-sugar rise, however, showed no characteristic relation to the menstrual period, and the position of the renal threshold seemed to be identical, before, during, and after menstruation. Nor did the calcium concentration of the blood serum, which varied between 7·8 and 9·8 mg. per 100 c.cm. in ten pregnant and one non-pregnant woman, seem to exert any influence on the hyperglycæmia or the situation of the threshold after an administration test.

Summary.

To recapitulate the results of the present experiments, it appears that the investigation of glycosuria after large doses of glucose, as recommended by many authors, is not valid as a diagnostic aid in pregnancy, because glycosuria occurs relatively frequently in non-pregnant women, while it is far from being constant in pregnant ones. Second, the experiments prove that there is a curious and characteristic difference in the blood-sugar rise and position of the renal threshold in the first and second periods of pregnancy. Early in pregnancy the position of the threshold is normal and the blood-sugar rise is often remarkably high, so that the glycosuria is due to

FIG. 2.



Carbohydrate tolerance in a patient of 42. A, before operation, May 18th; B, before operation, May 21st; C, corpus luteum extirpated, June 2nd; D, uterus evacuated, June 13th.

the marked hyperglycæmia and is not, as is generally believed, of renal origin. In the latter part of pregnancy, on the other hand, the blood-sugar rise is usually small but the renal threshold nevertheless, is often so low that glycosuria frequently occurs, which therefore, in this stage of pregnancy, can rightly be termed renal. Finally, the work has made it probable that the corpus luteum causes the large and prolonged blood-sugar rise which is characteristic of early pregnancy, while the low renal threshold in the later months appears to be dependent on the fœtus or placenta.

RICKETS AND CHOLESTEROL.

BY O. ROSENHEIM

AND

T. A. WEBSTER.

(From the National Institute for Medical Research, Hampstead.)

WITHOUT discussing the already extensive literature of the subject[1] it may be said that the pre-eminent importance of sunlight and ultra-violet rays in the prevention and cure of rickets is now generally recognised, and further that it has not hitherto found a satisfactory explanation. In connexion with the anti-rachitic effect of radiant energy, it occurred to one of us (O. R.) to associate it with an apparently unnoticed observation on the effect of light on cholesterol, made more than 20 years ago by Ritter (1901). His accidental observation that specimens of pure cholesterol, prepared 25 years previously by Schulze from gall-stones and lanolin, showed a drop in melting point of about 30° C. and had become yellow in colour, was afterwards confirmed by Schulze and Winterstein (1904, 1906) and shown to be due to the action of light. (See also Lewkowitsch, 1909.)

The possibility of an association of fat-soluble vitamin with cholesterol or a similar substance had also gained probability by the further study (unpublished) of certain colour reactions of cod-liver oil and liver fats of other animals, mentioned in a previous communication by Rosenheim and Drummond (1920). This assumption received further support by the discovery of Steenbock and Black (1924) that irradiation of food and inactive vegetable oils conferred growth-promoting and anti-rachitic properties on them. The activation of vegetable oils by ultra-violet light was confirmed by Hess and Weinstock (1924), and later these observers showed that the anti-rachitic properties of the irradiated oils were confined to the unsaponifiable fraction.

Action of Light on Sterols.

Guided by the consideration that the presence of sterols (cholesterol and phytosterol) is one factor common to the fatty secretions of the skin of man and animals as well as to vegetable oils, we were led to correlate the effect of light upon them with the production of an assumed anti-rachitic vitamin in both. In view of the observations of Schulze and Winterstein, those of ourselves, as well as those of the above-mentioned authors, we decided to investigate the action of light on cholesterol with regard to the photochemical production of a vitamin. The preliminary results of one part of these experiments, dealing with the growth-promoting vitamin A, have already been published by Drummond, Rosenheim, and Coward (1925),[2] and the present communication is concerned with the anti-rachitic vitamin D only. We are greatly indebted to Dr. Leonard Hill, F.R.S., for the use of the experimental animals which were fed under his control.

We soon established the fact that the action of ultra-violet light on sterols produces effects similar to those of ordinary light as observed by Schulze and Winterstein, but incomparably more intense. Thus, for instance, the melting point of pure cholesterol (from brain) fell from 148·5° to 125° C. after five hours' radiation from a mercury-vapour quartz lamp at a distance of 10 cm. Sitosterol (from wheat) similarly exposed showed a fall from 136° to 120° C. The melting point of coprosterol (from dogs' fæces) fell from 97° to 56° C. The latter well-crystallised substance was converted by the action of ultra-violet light into an amorphous yellow resin, whilst cholesterol and sitosterol, previously pure white, had become yellow. These effects are undoubtedly partly due to oxygen and to the ozone which is generated by the quartz lamp. In order to exclude this factor, which might possibly exert a deleterious action on any active principle formed, we decided to irradiate cholesterol in an atmosphere of nitrogen as well as in air. In view of the low penetrating power of ultra-violet rays and their subsequent absorption by the surface layer of cholesterol crystals, we used a solution of the latter in liquid paraffin. This solvent was chosen as it allows the passage of ultra-violet light and has no anti-rachitic properties by itself nor after irradiation. Preliminary experiments establishing this point also proved that, in the doses given, it had no purgative or other effect on rats. We had previously found that a watery suspension of cholesterol soon deposited a yellowish resinous substance on the sides of the quartz flask on radiation, thus preventing uniform action and an accurate dosage. A colloidal solution of cholesterol in water was also tried; it does not flocculate on radiation, but has the disadvantage of a low strength (0·25 per cent.).

Cholesterol easily dissolves in warm liquid paraffin, and a 2·5 per cent. solution was used. Whereas it crystallises out of this solution at room temperature, it was found that after radiation in a rotating quartz flask (in air or in nitrogen) it remained more or less in solution, thus indicating a physical or chemical change. At the same time the solution differs from the non-irradiated one by reacting with certain substances, yielding colour reactions which are still under investigation.

Experimental Results.

Our tests were carried out on rats, the technique usually employed in this laboratory being followed, the Sherman-Pappenheimer, 84, low phosphorus diet being used. Six rats were used for each series and the control. Diagnosis was made from radiographs of the animals killed at the end of the experimental period. We also determined the inorganic phosphate content of the mixed blood of each group.

Several series of experiments were made with cholesterol radiated in an atmosphere of nitrogen and also in air for periods of half an hour, five hours, and ten hours respectively. All the exposures to ultra-violet light were made in a rotating quartz flask. The doses varied from 0·2 mg. to 4 mg. of irradiated cholesterol and were administered per os daily to each individual rat by means of graduated capillary pipettes. The results are given in the table.

---

[1] For a review of the literature up to 1924 see Special Report Series No. 38, Medical Research Council, second edition, 1924.

[2] It has since been found by these authors (private communication) that the growth-promoting effect of irradiated cholesterol, previously reported, is not a lasting one. The action of irradiated cholesterol on growth is therefore apparently identical with that of ultra-violet light itself and would seem to consist, like the latter, in mobilising the animal's reserves of vitamin A or, as suggested by Steenbock and Nelson (1923), by compensating the insufficiency of the anti-rachitic principle.

* This rat died of broncho-pneumonia.

† This experiment had to be discarded, one rat having been partly consumed by its fellows.

Conclusion.

From these results it may be concluded : (1) That irradiation of cholesterol with ultra-violet light confers on it definite anti-rachitic properties, both in the presence and absence of oxygen. (2) Under the particular conditions of our experiments, increasing the time of radiation seems to increase somewhat the amount of anti-rachitic substance. (3) Taking the content of inorganic phosphorus in the blood as an index, it would appear that the limit of protection against rickets is reached by a dose of 0·2 mg., and this is especially marked in the half-hour radiation experiments.

During the progress of this work a communication appeared by Hess, Weinstock and Helman (1925), in which these authors reported results agreeing with ours in their main conclusion. They found that irradiation of a watery suspension of cholesterol or phytosterol conferred anti-rachitic properties on these substances. It may be remarked that in these experiments the lowest protective dose was five times as high as our lowest dose, and that their figures for the inorganic blood phosphates as a whole are on a lower level. These differences may find an easy explanation by the variation of procedure and the medium employed, and it is satisfactory to note that two groups of observers were led to the same result independently and guided by different considerations.[3]

Whilst it would be premature before further work has been carried out to assume the identity of the anti-rachitic vitamin with the active constituent of irradiated cholesterol, nevertheless the fact that anti-rachitic properties can be experimentally conveyed to such a well-defined chemical substance as crystallised cholesterol correlates the proved photosynthesis of this vitamin by the plant with its presumed photosynthesis in the skin, and thus affords a rational explanation for the beneficial effect of light in the cure and prevention of rickets. The presence of cholesterol and its derivatives in the skin and its fatty secretions, together with the easy absorption by the skin, of such fats rich in cholesterol as lanolin, would appear to strengthen the assumption that a vitamin formed from cholesterol in the skin under the influence of light would be easily absorbed and then liberated into the blood-stream.

These investigations are being continued, especially in the direction of elucidating the chemical changes which take place in cholesterol under the influence of light.

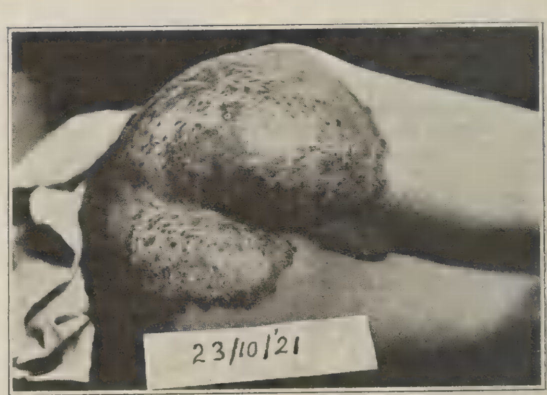
TREATMENT OF LUPUS BY IONISATION.

BY JAMES B. WHITFIELD, M.B.,
CH.B. GLASG.

HAVING had some gratifying results in treating lupus by ionisation, it was thought that an account of an extensive affection in a young man aged 18½, successfully treated by this method, might be of interest, and so an accurate record of the treatment given and progress made was kept.

The patient was sent to me in 1921. He had been suffering from lupus on the buttocks since he was two years old, a period of 16½ years. In making the diagnosis of lupus care was taken to exclude other skin affections, especially specific disease, of which no trace could be found, either historical or clinical. When treatment was commenced the disease was in active progress as is shown in Fig. 1, a photograph taken on Oct. 23rd, 1921. The thick advancing edge can be seen extending down the thighs. Fortunately the anus was not involved.

FIG. 1.



Before treatment by ionisation.

Technique.

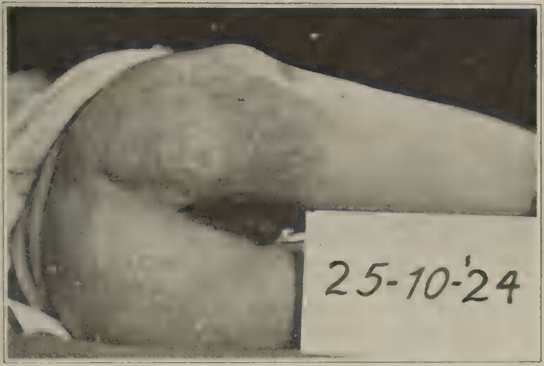
The affected area was thoroughly cleansed with warm water and soap, dried, and sponged over with a 5 per cent. solution of potassium hydrate, which was left on for three minutes and then washed off with warm water, the object being to remove the resistant layer of skin which covers the tubercles. The patient then sat in a papier-mâché bowl on eight thicknesses of "Turkish towel," under which was an electrode eight inches square. A 2 per cent. solution of zinc sulphate was put into the bowl in such quantity that the affected area was covered. The scrotum, which was not affected, was protected by being anointed with soft paraffin. The positive lead of the electric current was connected to the electrode in this bowl. The negative pole was in a similar bowl containing a 1 per cent. solution of common salt, into which the patient put his feet. A current of electricity was then turned on, beginning at zero, and slowly increased until it reached 40–50 milliampères, and was continued for about 90 minutes.

---

[3] While this note was in the printers' hands, a communication appeared by Steenbock and Daniels (J. Amer. Med. Assoc., 1925, lxxxiv, 1093) in which they mention, without giving details, that irradiated sterols possess anti-rachitic properties.

At first the treatment was repeated at intervals of 14 days. Improvement in the condition was soon manifest; the advancing edge cleared up in about three months, but the old tubercles, which had become, as it were, encysted, were much more resistant. It was due to these old lesions that the treatment had to be carried on so long; until the resistant covering is removed the passage of the ions is almost impossible and the treatment is of little avail. After treatment has been given there is a considerable reaction, which begins in two or three days and continues for three or four days. It gives very little trouble to the patient and always clears up. No dressing is required other than a clean cloth placed in the under-garment while the reaction is in progress.

FIG. 2.



After treatment.

During the three years treatment was given on 54 occasions as follows:—

First year 21, averaging 44 milliamps. for 84 minutes.
Second ,, 18, ,, 32 ,, ,, 77 ,,
Third ,, 15, ,, 27 ,, ,, 61 ,,

At the end of the second year the disease had practically disappeared, but the treatment was carried on as a safeguard against relapse. The final result is shown by the photograph (Fig. 2) taken on Oct. 25th, 1924. There is an extensive scar, as may be expected, but it is quite soft and shows no sign of contraction or thickening.

This case is one of many that have been treated by ionisation with similar results. It is chosen as an illustration because of its long standing and the extensive area covered. It had not been treated in any way other than by the application of ointments and lotions at various times.

Ilkley.

Medical Societies.

INTERNATIONAL ASSOCIATION OF THALASSOTHERAPY:

CONGRESS AT ARCACHON.

Dr. L. LALESQUE presided over the Fourth International Congress held on April 27th to 29th at Arcachon (Gironde), under the patronage of the President of the French Republic, when the treatment of rickets was the centre of discussion. Representatives of governments and learned societies attended a solemn opening session at 10 A.M. on April 27th. In the evening there were receptions and gala performances and a banquet. On April 30th visits were paid to neighbouring medical institutions, notably Fondation Wallerstein (Arès) and Moutchic (Lacanau-Lac), each known as a "preventorium." At these institutions children of tuberculous parents, deceased, are cared for, educated, and eventually placed out in the world in some occupation for which they are fitted. The children live almost entirely in the open air and the occurrence of tubercle among them is practically unknown. On May 1st the Congress went to Biarritz and in the evening members were entertained by the municipality at a banquet.

Representation.

The countries represented were England, France, Italy, Spain, Holland, Belgium, Roumania, Sweden, Poland, Czecho-Slovakia, Esthonia, Cuba, Algeria, Uruguay, and Monaco.

The following congressists were accredited delegates from different scientific bodies or ministries of health: England: Dr. W. Gordon (Royal College of Physicians of London), Dr. Howard Humphris (British Medical Association), Dr. G. L. Pardington (Royal Society of Medicine). France: Dr. Armand Delille, Dr. Chauveau (General Secretary of the Congress), Dr. Delcroix, Prof. Desgréz, Dr. Gimbert, Dr. Jaubert, Dr. Mercier des Rochettes, Dr. Monod, Dr. Pierret (General Secretary for the English Section), Dr. J. L. Pech, Dr. Sorrel, Dr. Schmitt. Italy: Dr. Bardisian, Dr. Ceresoles, Dr. Maragliano. Spain: Dr. Pinilla. Holland: Dr. Hartog. Belgium: Dr. André, Dr. Delchef, Dr. Watry. Roumania: Dr. Anastasiu. Sweden: Dr. Halle. Poland: Dr. Knug. Czecho-Slovakia: Dr. Vesely. Esthonia: Dr. Blumenthal. Cuba: Dr. Amoedo. Algeria: Dr. Piquet. Uruguay: Dr. Acevedo. Monaco: Dr. Vivant.

The following journals were represented: "L'Avenir d'Arcachon," "La Dépêche de Toulouse," "La France," "La Gazette des Sciences Médicales," "Le Journal de Physiologie et Pathologie Générale," "Le Journal de Médecine de Bordeaux," "La Presse Thermale et Climatique," "La Presse Médicale," "La Petite Gironde," "La Vigie," and "The Lancet."

THE MARINE TREATMENT OF RICKETS.

Dr. JEAN ANDRÉ opened the discussion by reading a paper on the Marine Treatment of Rickets. This treatment, he said, rapidly causes to disappear the enlarged tonsils, the anæmia, the loss of muscle and nerve tone associated with rickets. The pale, flabby, and deformed infant after a few months of the treatment is transformed into a robust, bronzed child. The treatment raises the whole resistance of the body and is an excellent prophylactic against tuberculosis. While the rachitic child may be treated in the town with massage and appropriate regimen and applications of ultra-violet rays, &c., the cure will be neither so quick nor so complete as if it had been carried out by the coast. The northern coast of France is exceptionally advantageous to the rachitic by reason of the wind, the continual movement of the air, and the actinic rays, and protection from them if they be too strong is always easy. Hazon says the ozone in the air has a soothing effect, as does also the wide expanse of horizon and freedom from crowds. After a few months' sojourn by the sea the treatment should be stopped for a few weeks. When a return is made susceptibility is increased and in this way the good effects of the treatment are augmented. As large an area as possible of the skin should be exposed so that a maximum of radiation may be absorbed. In spite of crooked limbs the little patients should be allowed to walk about the sand, thereby increasing both muscular and nerve tone. In most cases the use of plaster is to be deprecated, though in genu valgum it may be used with advantage.

Dr. ARMAND DELILLE followed with a paper on

Rickets, its Pathogenesis by Deficiency of Sunlight and Helio-Marine Treatment.

Heliotherapy and sea-bathing, he said, are treatments which only commenced to be used in the latter half of the nineteenth century. The first results followed the establishment of the hospital at Berck sur Mer and shortly after this several other similar institutions were erected. The treatment consisted in allowing the children to play on the beach followed by supervised bathes in the sea. It was later discovered that the absence of vitamins was only a contributory cause of rickets, and that the faulty assimilation of calcium and phosphorus was due to absence or deficiency of sunlight. Dr. Alfred Hess, of New York, making observations on 2000 cases of all classes discovered that cases of rickets occurred when sunlight was deficient, whatever the diet, that Negroes were more affected than whites, and that of the whites there were more cases among southern races. Also the incidence was greater in the spring than in the autumn, all facts pointing to the absence of light as the essential cause. Rachitic children treated with heliotherapy for other diseases, such as tuberculosis, improved in a remarkable manner, and the amount of phosphorus and calcium in the blood was considerably increased. Normally the calcium-phosphorus content of the blood is highest in July and August. Helio-marine treatment should be started as early as possible, for when the first stigmata, such as bony changes, are observed, the disease has already been present for some time. There is nothing to take the place of real sunshine, and the use of a quartz-lamp should be regarded as only a temporary makeshift. In the summer months the best situations are on the northern French coasts; the Mediterranean Littoral should be chosen during the winter. The method of treatment is to expose the lower extremities three times in the space of an hour for three minutes on the first day, the following day the time is increased to five minutes, while the forearms are exposed for three minutes. The area is extended in this way till the whole body is exposed. Treatment must be continued until the rachitic stigmata disappear or are arrested. The cure should always be undertaken under medical supervision, and the value of sea-bathing, massage, and good food must not be forgotten.

Dr. EDOUARD DELCROIX dealt further with the

Marine Treatment of Rickets.

The marine climate, he said, is really specific in the treatment of rickets. A course carried out with method and of sufficient duration (at least a year to a year and a half in rickets of early infancy and six months in cases of adolescent rickets) will produce a cure. When children are treated by the sea sufficiently early, most of the bony deformities disappear without recourse to surgery. It is a great pity that seaside towns make so little provision for sea-baths. It is an absolute essential for the cure in winter and at all times for fat, pasty children, and for those in whom development is delayed. The mode of action of the treatment is complex. The changes are of a physical nature, chemical and even electrical, and it is their combination which produce the remarkable effects of climatic treatment. A sojourn by the sea unites all the conditions favourable to the cure of rickets.

Dr. LEONARD HILL and Mr. A. WEBSTER presented a

Report on Rickets,

which was read by Dr. W. GORDON. Rickets, states the report, is a disease of civilisation. The incidence reaches its height in winter and declines in summer. Mellanby was responsible for the modern theory that the disease was due to deficiency in vitamin A. It has later been shown that the disease could be produced by withholding inorganic calcium and phosphorus. In 1919 Huldschinsky reported cures of rickets with the quartz-mercury vapour lamp. Experimentally he showed that the effective rays were of a wave-length of 300 Å or shorter. In rickets the blood is low in inorganic phosphorus and calcium. Cod-liver oil and ultra-violet light both increase the concentration of these substances in the blood and this takes place by means of increased absorption from the intestinal tract. For this reason it has been held that the primary seat of rickets is the gastro-intestinal tract. The rachitic animal has not lost the power of bone formation, but lacks the necessary materials. From the results of experiments these workers "feel justified in making the broad generalisation that provided that an animals is supplied with food just sufficient to maintain life and a little growth and is given the bare minimum of bone-forming elements, calcium and phosphorus, then if ultra-violet light be supplied in an adequate amount rickets will not develop however unfavourable the animal's environment be."

Dr. HOWARD HUMPHRIS read the paper on

Light in the Prevention of Rickets,

which appeared in THE LANCET, May 2nd, p. 912.

Dr. JAUBERT said: Rickets is most frequently found in towns and overcrowded quarters. It is due, not so much to errors of diet, as to unsuitable conditions of living as regards habitation, lack of air, light, and sunshine. Statistics, including a majority of severe cases taken between the second and fourth years, show that treatment by the sea produces 95 per cent. cures or definite improvement. The results are better still when treatment is started before deformities have appeared. In the marine cure, other complex agents also take part, air, sun, light, sea-water, and it is impossible to dissociate their actions and effects, but it must be admitted that the light of the sun takes a preponderant part in the cure of rickets.

Dr. MERCIER DES ROCHETTES contributed an

Analysis of the Action of Marine Treatment on Rickets.

It has been proved, he said, that rickets can be arrested completely by such treatment. Children should be sent when quite young to the coast in order to obtain a rapid and complete cure, and special provision should be made for infants as young as 15 months. The stay by the sea must be prolonged till cure is obtained. The time varies with the age of the child, the gravity of the lesions, and the climate, and the best situation is where treatment can be practised all the year round. The treatment should consist of life in the open air, warm and cold baths, and heliotherapy. Under the age of 4 years deformities disappear generally completely, from 4 to 7 years considerable improvement can be expected; after the age of 8 years marine treatment has no effect on deformities. The keel-shaped chest can nearly always be completely cured, the deformities of the lower limbs can be improved, except the antero-posterior curve in the tibia which is resistant to thalassotherapy. Ultra-violet rays from the quartz mercury-vapour lamp cure rickets in children of 6 months to 2½ years. It improves the general condition and has some action on the calcification of bones. Natural heliotherapy by itself and far from the sea ameliorates rickets. Sodium chloride baths and artificial salt baths alone cure rickets at all ages. They not only improve the general condition, but diminish the deformity. Living in the open air by the sea is enough to improve considerably the general health and improve deformities up to the age of 7 years. Marine aerotherapy with heliotherapy combined is the best treatment as much for a preventive as for a curative agent.

Dr. ROBERT PIERRET (Hon. Secretary to the British Section) spoke on the relation of

Thermal Cures at La Bourboule

to seaside treatment of rickets. In the same manner that surgeons endeavour to stop deformities in the legs Dr. Pierret corrects thoracic deformities in rachitic children. The method is to treat the nose and throat by hot arsenical and radio-active thermal baths. The local treatment both before and after removal of adenoids disinfects the respiratory tract and renders the air passages free from obstruction. The passage for the air being then sufficient the air pressure in the lungs is no lower than the atmospheric pressure, so that the ribs are in perfect dynamic equilibrium. The baths act on the general system at least as well as sea-bathing, but the thermal cure is enhanced by a subsequent holiday by the sea. If the stay by the sea precedes the thermal treatment results are much less favourable. The waters at La Bourboule are highly arsenical, equivalent to 32 drops of Fowler's solution per litre. The favourable action of arsenic in the treatment of rickets is well known, and has recently been investigated by Prof. Hill at the National Medical Research Institute at Hampstead.

Dr. W. G. **SUTCLIFFE** outlined the advantages of the

Royal Sea-Bathing Hospital at Margate,

which was commenced as long ago as 1796. The building, he said, was considerably enlarged and modernised in 1882 and was still further enlarged in 1920. The present accommodation is for 265 patients, of which 100 are children whose education is carried on in the hospital. Hot and cold sea-water baths are provided in all the wards which are now arranged to open on either side on to covered verandahs so that patients can remain in the open air night and day. Sea-bathing is carried out by all patients that are fit for it during the summer months. Since 1904 the therapeutic agency of X rays has been freely utilised and the results obtained have been highly successful. Dr. Sutcliffe showed photographs of the wards and patients undergoing treatment.

Dr. J. L. **PECH** spoke on the

Biological Antagonism of the Infra-Red and the Ultra-Violet Radiations.

It has been known for a long time, he said, that the infra-red and ultra-violet rays are antagonistic and biologically opposed. It is generally forgotten that they nullify each other when acting simultaneously on a living subject. Experiments have led to the following conclusions, that it may be possible by an appropriate radiation to annihilate the effect of another radiation in action at the same time on a living subject; that two radiations can only be antagonistic to physio-chemical equilibrium in so complex a structure as the living organism, and their actions may vary with the particular organism. The effect of ultra-violet radiation on man is to produce an erythema and certain blood changes. If infra-red rays be exhibited simultaneously these effects are very much diminished or completely lost. The dosages in heliotherapy are imperfect and the infra-red rays are not taken into account, so that the results obtained are often diverse. Sunlight is withstood without marked skin changes by virtue of the infra-red rays, but when these are filtered, for example, by steam or moisture which occurs on heights and glaciers, dermatitis is very frequent, and for the same reason skin changes are more marked at the seaside than inland. The practical result of this is that it will be found in the future better results will be obtained in the cases of local treatment by using artificial sources of radiation so that only those rays required may be selected.

The next Congress will be held in three years' time, probably in Roumania.

ROYAL SOCIETY OF MEDICINE.

SECTIONS OF OPHTHALMOLOGY AND COMPARATIVE MEDICINE.

DISEASES OF THE EYES COMMON TO MAN AND ANIMALS.

THIS formed the subject of a joint discussion by these sections of the Society on May 8th, Sir **ARNOLD LAWSON**, President of the Section of Ophthalmology, being in the chair.

Mr. **HUMPHREY NEAME** opened with a paper on

Parenchymatous Keratitis in Animals.

He gave an exhibition of slides by the epidiascope and their description. The first illustrated a central rupture of the cornea of a sheep caused by a turnip striking it. Five days after the injury a very acute infection of the eye had occurred. Clouds of nuclei could be seen between the lamellæ, and the anterior chamber, between cornea and iris, was filled with purulent material. A layer of pus could be seen between the ciliary body, iris, and lens. Polymorphonuclear cells were abundant, and there was active suppuration. A ring abscess had occurred, the ring consisting of dense infiltration. Excision was not done in one case of keratitis, and the eye showed attempts at repair as extensive vascularisation had taken place. The polymorphs were replaced by round cells. In a less acute case, in a guinea-pig, the state of affairs was only evident on histological examination. Clinically the cornea was intensely opaque throughout, and during life there was an irregularity in its centre and its diameter was three or four times greater than normal. At the edge of the wound an attempt at repair could be seen, a downgrowth of epithelium filling up the edges of the wound. The pattern of the remainder of the cornea was largely lost, and there was marked cell infiltration. The next case demonstrated was one of tuberculosis in the eye of a cat. It was examined clinically before death, and the retina of one eye was detached. Both eyes were blind. In the eye most carefully examined there was a mass of tuberculous infiltration at the corneo-scleral junction, and multiple tuberculous nodules were seen in the iris and ciliary body. There was present a typical parenchymatous keratitis, and an intense lymphocytic infiltration, with a mass of cells on the back of the iris. This cat had tuberculous irido-cyclitis. Tuberculous parenchymatous keratitis occurred by extension of the disease from neighbouring structures. In this case the whole substantia propria was much infiltrated, also the fibres of the ligamentum pectinatum. At the corneo-scleral junction there was an almost staphylomatous condition.

Mr. Neame showed also sections from the eye of a rabbit which had tuberculosis from the subcutaneous inoculation of a tuberculous culture, mostly from lupus vulgaris of the human skin. Here a tuberculoma was evident at the corneo-scleral junction. In another tuberculous eye there was marked papillitis and extension of the tuberculous process into the optic nerve. A further case was one of distemper in a dog, and he showed a micro-photograph of a piece of the cornea. When seen clinically, the cornea was full of a network of vessels. There was intense infiltration, and a great overgrowth of connective-tissue cells. A section of an eye in an early case of distemper showed, clincally, nothing more than a slight haze of the cornea. Vascularisation was both deep and superficial. The cornea from a case of trypanosomiasis showed thin lines in the periphery and vessels extending a short way into the cornea. A mass of cell exudation extended into the anterior chamber, and the whole sclero-corneal junction and ciliary body were infiltrated. Trypanosomes were abundant in the specimens.

Mr. **HENRY GRAY** contributed a paper on

Ulcerative Affections of the Cornea,

their Complications and Sequelæ. He said this ulceration might occur in association with influenza in the horse, swine fever, trypanosomiasis, rabies, and as a result of infections of the conjunctiva. It was seen sometimes also when tuberculosis attacked the eye in oxen, sheep, cats, and dogs, in epizoötic lymphangitis, and in specific ophthalmia in the ox and the horse. In the dog this ulceration might be a sequel of paralysis of the ophthalmic division of the fifth nerve, or of tumours involving the roots of the nerve. In the horse and the cat, in which the cornea was thick, excavated ulcers were met with, but repair took place without much difficulty. Accompaniments of these ulcers were intense photophobia, lacrymation, and powerful blepharospasm. In the case of a wide ulcer, paracentesis should be carried out without delay, in order to avoid a large spontaneous perforation. When photophobia and blepharospasm were present, cocaine drops should be instilled to relieve the conjunctival congestion.

Mr. A. F. MacCallan read a paper by himself and Mr. Herbert Mason on

Cataract in Horses,

with some reference to iritis. The paper was based on the experiences of the writers in Egypt. Many varieties of cataract were to be seen in both man and the horse, including anterior polar, capsular, posterior capsular, cortical, lamellar secondary to irido-cyclitis, traumatic, and the dotted cataract of congenital origin. He said the mere presence of one or two opaque dots in a lens might not interfere with an animal for draft or riding purposes, but an extension of the opacity would make it useless for the saddle and for breeding, as most cataracts in horses were hereditary. Glasses could be provided for horses, but as the native Egyptian was satisfied with his lensless eye after the operation, glasses were deemed unnecessary for horses. He described the operation usually performed on the horse, and criticised the method of lens extraction set out in Woolridge's edition of Woodruff's work. In horses in France during the war there was a condition known as periodic ophthalmia, a form of irido-cyclitis. The animal had photophobia, with inflamed conjunctivæ, and the cornea was very hazy but not ulcerated. Also the iris was inflamed, and it was impossible to keep the pupil dilated with atropine. It was not a contagious disease, and could not be reproduced by injection of the eye humors into a healthy animal. It seemed to be due to some general disease, and post mortem there were found many opacities of the lens and flocculent opacities in the vitreous.

Discussion.

General Sir John Moore spoke in a general way of the eye diseases in army horses which occurred during the war in France. During that time there were 36,690 cases of eye disease in horses, and of these 19,813 were cured, while 2558 animals were destroyed, and 9723 cast and sold, the last-named being eagerly used as food. The most serious cases in these horses were those due to periodic ophthalmia, and at a conference with the French veterinary authorities careful consideration was given to this well-known disease, called in the old coaching days "moon-blindness." Horses which had this condition got very fat and were apparently healthy, but had to be relegated to work on the lines of communication. At one time during the war there were over 2000 horses being treated for periodic ophthalmia in France. Some veterinary officers believed the disease to be contagious, though the majority did not. Bacteriological examinations did not reveal any causal organism, and the disease was apparently as common in outside standings as in stables. Sir John Moore's own view was that bad sanitation was at the root of the disease, for during the war the animals were amidst great collections of fæces and urine.

Major Dunkin said that in the keratitis seen in distemper in dogs the precedent condition was a conjunctivitis, accompanied by a profuse secretion of tears. It was only when the disease became chronic that a corneal opacity appeared.

Mr. M. B. Oliver referred to an epidemic of periodic ophthalmia which he saw near Ypres in 1918. Contrary to what Sir John Moore said, many of these animals were obviously quite ill. He noticed they had iritis and cyclitis, with enormous exudates in the anterior chamber. In some the cornea was quite opaque. In all the cases he saw the horses were blind.

Mr. Gray Clegg spoke of the occurrence of hairy moles on the corneæ of dogs, and of cataract in older dogs.

Mr. T. Harrison Butler described his experience in doing cataract extraction on a friend's King Charles spaniel. When he introduced the discission needle behind the iris and turned the lens down and removed the needle the lens sprang back, and this was repeated two or three times. Ether was then given and another attempt made, and as the anterior chamber became filled with blood he desisted.

Dr. Rayner Batten referred to nystagmus in dogs, and double detachment of the retina in a cat. Very little provocation would produce interstitial keratitis in a dog's cornea. He had done an advancement operation for marked internal strabismus in a bulldog. Prominent eyes in dogs were very liable to become ulcerated, and if the ulcers perforated there was likely to ensue a secondary form of glaucoma.

Prof. Woolridge said that in his hands the treatment of glaucoma in the dog had been most unsatisfactory. Certainly extensive opacity occurred in that animal on slight provocation, but in most cases it cleared up. Dermoid growth in the eye of the dog could be easily dissected off. Though a considerable portion of conjunctiva carrying the hair might be excised, only a small permanent opacity remained. He did not think the stricture passed by Mr. MacCallan on Prof. Woodruff's description of the operation for cataract was justified.

Mr. Treacher Collins spoke of the occurrence of parenchymatous keratitis in some pheasants at a shoot in Norfolk. These birds refused to rise, however nearly they were approached. One was sent to him for examination, and he found it had a vascular cornea and a typical interstitial keratitis. There was much cellular exudation and a marked development of vessels in the substance of the cornea. He asked whether veterinarians saw sympathetic ophthalmitis. He preferred for the disease which had been spoken of as periodic ophthalmia the term "periodic ophthalmitis." He had a specimen of dermoid growth in a pig's eye, which showed bristles sprouting out from the cornea, and in the Royal College of Surgeons Museum there was a specimen of a sheep's eye showing a tuft of wool.

Mr. Tudor Thomas spoke of a case of sympathetic cyclitis in a dog, both eyes being involved following injury to one.

Mr. George Mackay (Edinburgh) referred to the readiness with which keratitis occurred in a dog which suffered a small perforation, and the facility with which it cleared up again. He described a case in which he removed the lens in a dog for cataract, and had a difficulty in getting it away, as it seemed to be, in comparison with the human, large, hard, and round. No sepsis ensued.

EXHIBITION OF CASES.

Snowball Opacities in Vitreous.

Dr. A. Hugh Thompson showed a man, aged 62, who had the vitreous of one eye filled with round white bodies, which moved with the globe in any direction. The fundus appeared normal, and the vision did not seem to be impaired. Vision was R. 6/12, L. 6/18. Some considered the condition was congenital, but this man had only noticed it of late years. The bodies were too large and dull for cholesterine crystals.

Tuberculous Keratitis in a Cat.

Mr. Hamilton Kirk showed a case of this condition and directed attention to its frequent occurrence in this animal. This cat showed the disease in an early stage; it was brought to him six weeks ago, and there was only to be seen at present an amaurotic state of the pupil. He expected such lesions as detachment of retina to occur later. Tuberculosis affected the eye in cats, in addition to other organs, with remarkable frequency. There were nodular protuberances on the kidneys of the cat shown. 60 per cent. of dogs with distemper seemed to have eye trouble. In the human the nearest disease to distemper in dogs was measles, and eye troubles were not infrequent in measles. He thought the infection spread through the nasal duct, through the stoppage of the channel for tears. In cats there was a catarrhal form of distemper, with chemosis, swollen conjunctiva, photophobia, pain, and the secretion of a thick, cream material, which glued the lids together.

Mr. NEAME referred to a paper dealing with eight cases of tuberculosis in cats, in all of which both eyes were affected. Coats found tuberculous masses in the choroid, with a variable degree of retinal detachment.

MANCHESTER MEDICAL SOCIETY.

A MEETING of this Society was held on May 6th, Prof. G. R. MURRAY, the President, being in the chair, when Mr. H. MORRISTON DAVIES read a paper entitled Observations on the Diagnosis and Treatment of

Intrathoracic Disease.

In the first part of the paper five cases of particular interest, either as regards diagnosis or treatment, were described: 1. Gumma of the lung simulating tuberculosis. 2. Primary bronchial carcinoma, discovered accidentally by the X rays in a patient suffering from chronic bronchitis and emphysema. The diagnosis was made originally on the radiogram, then made more certain by the appearance of characteristic symptoms, and finally confirmed by operation. 3. That of a woman who for 30 years had attended hospitals for dyspepsia, dyspnœa, and tachycardia. X ray examination revealed a diaphragmatic hernia. 4. Unilateral bronchiectasis, due, it was discovered as a result of treatment, to fragments of teeth which must have been in the lung for ten years. The bronchiectasis was treated by artificial pneumothorax and phrenicotomy. Following collapse of the lung, fragments of tooth were expelled. Later, owing to the lung creeping out, the symptoms returned and a thoracoplasty was done. Following this a still larger fragment of tooth was coughed up, since when the patient had remained perfectly well. 5. That of a man wounded in the neck by shrapnel, which caused mediastinal suppuration and chronic pneumonia. The consequence of this was bronchiectasis with offensive sputum. The shrapnel in the base of the lung escaped notice until an X ray was taken with very oblique rays (from above downwards). Phrenic evulsion was done, paralysing that dome of the diaphragm. Since then there had been disappearance of all symptoms.

The second part of the paper was devoted to a description of the value of phrenic evulsion and thoracoplasty. Phrenic evulsion had superseded phrenicotomy because it broke the continuity of the accessory phrenic as well as the phrenic itself. It was therefore much more effectual and almost constantly resulted in paralysis of one-half of the diaphragm, the dome on that side rising up into the thorax and producing partial collapse of the base of the lung. The operation was of value for basal tuberculous and bronchiectatic lesions of the lung; for abolition of diaphragmatic cough; for relief from vomiting associated with coughing; as an aid in cases of partial pneumothorax; as a means of reduction of the pleural cavity in cases of chronic effusion; as a preliminary to thoracoplasty, as a means of testing the resisting capacity of the opposite lung; and was a prophylactic measure against onset of bronchiectasis in cases of unresolved pneumonia. The statistical results of thoracoplasty were practically the same as those for pneumothorax —i.e., 35 per cent. healed, 30 per cent. improved, 35 per cent. uninfluenced or worse. The operative mortality was about 8·5 per cent. It was indicated in unilateral (or mainly unilateral) cases of tuberculosis in which there were extensive mechanical changes and in which artificial pneumothorax was impossible owing to adhesions; also in unilateral bronchiectasis. Slides were shown illustrating the collapse of the lung and chest wall, and the comparatively slight resultant outward deformity.

Reviews and Notices of Books.

THE LIFE OF SIR WILLIAM OSLER.

By HARVEY CUSHING. Oxford: At the Clarendon Press. 1925. In two volumes. Vol. I., pp. 685; Vol. II., pp. 686, and Index. 37*s.* 6*d.*

Osler was the son of a Canadian rector who held the livings of Ancaster and Dundas not far from the Western end of Lake Ontario, and the boy was fortunate in his teachers, who were a cleric, William Arthur Johnson, and James Bovell, who only took orders late in life, but at the time when Osler was his pupil was a medical man and dean of the medical department of Trinity College, Toronto. They were both remarkable men and somewhat eccentric. They clearly possessed a large share of Osler's affection, and though their methods of teaching must have horrified their stereotyped colleagues, they evidently exercised enormous influence upon their pupil. Dr. Cushing gives many letters from them both, and in one from Bovell, who was notoriously absent-minded, we find a sidelight upon Osler's possible choice of a career and also an example of the teacher's wandering mind, for the letter is dated August, 1870, and he says to Osler, "I do hope you will work on, for I have quite made up my mind that you are to get a first-class for the East India Company." The East India Company was handed over to the Crown in 1858, and had therefore ceased to exist. From Toronto Osler passed to the medical school of McGill University, where he was appointed quite shortly professor of the Institutes of Medicine, being then only in his twenty-sixth year. In 1884 he left Canada, to the deep regret of his colleagues, for the United States, being elected professor of clinical medicine at the University of Pennsylvania. And in 1888 came the call to the Johns Hopkins University at Baltimore as professor of medicine and physician in charge of the medical department.

One of the outstanding incidents of his Baltimore days was the publication of the "Principles and Practice of Medicine," the result of clinical studies based alike on personal experience and on theories fortified by the wide consultation of the best German, French, and English authorities. The book was written with difficulty; we can see that Osler was consumed with the desire to write it, but painfully aware of the labour that he would be undertaking, and of the calls that the task would make on his over-occupied time. However, the task was steadily accomplished, and the work was recognised at once as a great acquisition to medical literature. There were at the time several books, notably those of Taylor, just issued, Bristowe, Roberts, and Fagge, which covered the range of medical study to the satisfaction of students and of their examiners, but Osler's treatise appeared at a time when not only modern developments required recording, but when a new spirit of approach was badly needed in response to altered central conceptions concerning disease. The observation, lucidity, and powers of judgment displayed made the book an immediate success, for the author contrived to give the lessons to be learned from the latest pathological investigations in combination with his own personal clinical observations, while he boldly accepted new theories of disease and new classification in accordance with the progress of knowledge. It was at Baltimore also that he developed the admirable plan by which clinical medicine should come directly within the sphere of University training, being placed alongside the other great faculties, the associated hospitals and institutions being regarded as schools of the University. With such a record it is not surprising that, when in 1905 he was appointed Regius Professor of Medicine at Oxford, the mother country was ready to welcome her great Canadian recruit.

The second volume of the book is largely given up to a description of Osler's Oxford career, a career in which he was not only happy to himself but a source of incomparable happiness to others. After the strenuous hustle of American life the atmosphere of Oxford appealed particularly to him. He delighted in the congenial society, and the duties gave him ample scope for his activities and free play for his broad outlook on life, facts which are proved over and over again by the correspondence included in the volume. We have here also a very full picture of the war, for Osler, it will be seen, was a firm link between the medicine of America and Canada and that of the Allies. We can see from the letters included that throughout the protracted struggle he worked heart and soul for the sick and wounded, and when the blow fell that saddened the end of his life by depriving him of his only son, he reacted to it by a deeper immersion in innumerable duties in connexion with the hospitals under Canadian and American control. On p. 577 is an extract from a diary kept by a brother officer of young Revere Osler, describing his burial: "A strange scene—the great-great grandson of Paul Revere under a British flag, and awaiting him a group of some six or eight American army medical officers. . . ." The significance of the note is that Paul Revere, after whom young Osler was named, was the notable revolutionary who made the famous midnight ride in 1775 from Charlestown to Lexington to warn the population of the landing of the British.

These large volumes bring before us the manner of man that Osler was by the recapitulation of internal evidence. We see him as one with unbounded powers of sympathy, kind, learned, and humorous, a model physician and teacher, and a reformer. He was able to combine deep respect for all that the old offered which was worth retaining, and with this acute perception of the debt owed by the present to the past, he possessed an equally acute perception of the directions in which reliance upon what had gone before can be placed as a guide to what should come. There is ever a tendency for one who essays to put on paper the portrait of a rare and charming personality to record every scrap of fact or detail which may throw a light upon his subject; the result may then be to demand from the writer exceptional qualifications. Not that we mean by this that he need be either learned or literary—both of which Prof. Cushing distinctly is, and neither of which was Boswell, the classical biographer for all time—but he should have great powers of assimilation so that the homogeneous information can be mentally digested and arranged before it is published—that is, if he wishes to write a popular book. Prof. Cushing has (and rightly) as profound an admiration for Osler as Boswell had for Johnson, but many will find that he has allowed his biography to be overloaded with details some of which obscure instead of throwing light upon the hero. It would be fair criticism to say that the result of more concentration would have been likelier to obtain for a life of Osler the popularity which it deserves, but it would certainly be quite unfair to blame the author for not having done what he has never attempted to do, or to assume that he could not have done it if he wished. Prof. Cushing has decided to give us all the information that we may digest it and make the great deductions for ourselves from a work of the highest interest.

PSYCHIATRY.

The Inheritance of Mental Disease. By ABRAHAM MYERSON, Professor of Neurology, Tufts College Medical School. London: Baillière, Tindall and Cox; Baltimore: Williams and Wilkins. Pp. 336. $5.

WITH this volume Prof. Myerson presents in an authoritative and lucid manner the results of many years' study of the hereditary factors of mental disorder. He discusses the whole conception of insanity and shows that, by departing from the use of the term "insanity," the approach to the subject as a group of "diseases of the human being to be studied in a naturalistic manner and clinically" is made more easy. He takes the attitude that there are independent groups of mental diseases, some of which he finds to have no hereditary value, while others run in families. He criticises the various theories of the heredity of mental disease and is inclined to the view that the transmissible mental diseases are not really hereditary characters in the same sense as stature or blue eyes, for example, but that they merely represent diseases caused by unknown agents whose effects persist over two or more generations and from which a stock may either recover or die out. Finally, he deals with the value of the problem in the racial life, for, as he says, "if a true heredity is involved, then our humanitarian efforts are injurious to the race, but if the problem is not one of heredity, then our social efforts are racial efforts and our noblest strivings have a eugenic backing."

The work is admirably presented. Prof. Myerson departs entirely from the text-book style of description; he takes the most prominent symptoms and describes them in such simple language as can readily be understood by those unfamiliar with the technical phraseology of the psychiatrist. In his grouping of mental diseases he takes a toxic group, a psychoneurotic group, an epileptic group, a feeble-minded group, and a group of five mental diseases, of which the underlying pathology is as yet somewhat obscure. These "conditions" (a term which he prefers to "disease") are dementia præcox, manic-depressive insanity, paranoid psychoses, involutional diseases, and senile dementia. It seems probable to him that in all the periods of life there occur three main types of mental disease: the first is a paranoiac type with hostility, suspicion, a deluded interpretation of the life around, and a gross egoistic over-evaluation of the self; the second is a dementing disease whose prototype is dementia præcox, but which occurs in modified form in the involutional and the senile periods; while the third is a disease marked mainly by a depressive mood with lowered energy, absent interest, and delusions of a depressive and apprehensive nature, occasionally associated with excitement and exaltation. Whatever their cause, the less resistant individuals develop these conditions early, others remain normal until the change of the involution, and still more resistant individuals develop them late in life.

The remainder of the book consists of a detailed and thorough exposition of the material which the author has collected during the years in which he has been working. He divides it up into sections dealing with the transmission of specific mental disease in the vertical line and the transmission horizontally. He concludes as regards the vertical transmission: (1) That the paranoid disease tends to paranoid states, perhaps finally to dementia præcox. (2) That the manic-melancholic diseases are in the main followed out, but in a certain number, especially in doubtful cases, they may be followed by dementia præcox. (3) That the involutional and senile state, if paranoid, trends towards paranoid states and dementia præcox. (4) That the manic-depressive states of involution and the senium trend towards manic-depressive states and dementia præcox, especially the latter. (5) That dementia præcox in an ancestor trends towards dementia præcox in the descendants with a certain scattering incidence of imbecility. (6) That neither for organic disease nor for alcoholic disease can anything definite be said. The conclusions concerning the horizontal transmission are as follows: (1) The psychoses of brothers and sisters tend on the whole to be alike. (2) An apparent exception is the frequency of the statement that one or other of the brothers or sisters with dementia præcox is also mentally defective. This he believes to be due to the more early occurrence of the disease, and his observations corroborate the belief of Kraepelin that some cases of feeble-mindedness are really early cases of dementia præcox. (3) His own experience throws doubt on the occurrence of typical mental defect and typical dementia præcox in brothers and sisters. He says: "It will thus be seen that brothers and sisters are more alike in types of mental disease than are parents and descendants. This is what one would expect if there is a greater similarity biologically and socially between members of the same generation than between members of two generations."

The book ends with a warning against any attempt to influence legislation in a eugenic direction. Prof. Myerson recognises, however, a basis for the demand that no one should be allowed to conceal the fact of mental disease when entering upon marriage, and that such concealment should be a cause for annulment. He advocates sterilisation of those types of feeble-mindedness which are known to run in families, and he is of the opinion that wherever mental disease exists in a family group for more than one generation it would be wise for society to sterilise those of the second generation who pass into institutions. "I do not believe," he says, "that we can ask much more than that in the present state of our knowledge, and we cannot afford to be unduly dogmatic. The common sense and stolidity of legislatures, what seems to be stupidity, is often enough justified by the dogmatic attitudes of science, a dogmatism hard to understand by one who knows the history of the theories of science."

This work is in every respect a valuable contribution to the literature of the subject and can be recommended to all concerned with these branches of science.

Heredity in Nervous and Mental Disease. By Various Authors. New York: Paul B. Hoeber. 1925. Pp. 332. $3.75.

THE third volume of the reports of the Association for Research in Nervous and Mental Disease is an important contribution to the subjects there reviewed. The work is divided into five sections. The first deals with general considerations, including the rôle of the cell and the chromosomes and the significance of exogenous and endogenous factors in heredity. This contains an excellent review by Dr. Charles Metz of work in connexion with the examination of the chromosomes of the fruit-fly, Drosophila, which is of the highest importance and interest. There is also a paper by Dr. L. F. Barker on the significance of certain factors, such as consanguinity, race, and alcoholism, in the development of the heredo-familial diseases of the nervous system. The second chapter is a study by Dr. Smith Ely Jeliffe of the parts of the central nervous system which tend to exhibit morbid recessive or dominant characters, and outlines the work carried out by many observers in connexion with the hereditary aspect of nervous and mental disease, such as the familial muscular dystrophies, disseminated sclerosis, epilepsy, and dementia præcox. Chapter III. deals with the pathology of diseases of known hereditary tendency, particularly Freidreich's ataxia, amaurotic family idiocy, Leber's disease, and retinitis pigmentosa. A final section, by Dr. Charles R. Stockard, gives an account of the experimental work he has done on the production of congenital malformations by means of chemical traumata. The fourth chapter considers Heredity in the Psychoses, the hereditary and familial factors being dealt with by Dr. A. M. Barrett, the pathological changes in patients dying from hereditary and familial psychoses by Dr. S. T. Orton, while Dr. C. B. Davenport discusses the proportion of feeble-mindedness in such hereditary conditions. An interesting chapter is contributed by Dr. J. Collins on the attitude of the novelist to the hereditary factor in life.

The book is enriched by many excellent histological plates and genealogical tables and other illustrations, and includes discussions which took place in the society, following the presentation of the various papers. The wide scope and detailed survey of the field of research given in the volume render it a work worthy of careful and diligent study on the part of those interested in the hereditary aspect of mental and nervous disease.

THE MEDICAL, DENTAL AND PHARMACY DIRECTORY OF SOUTH AFRICA.

Edited and published by EWALD HERBERT. Johannesburg. 1924. Pp. 259. 15*s.* 6*d.*

THE area covered by this directory includes the Union of South Africa, Northern and Southern Rhodesia, and South-West Africa, Basutoland, and Swaziland Protectorate. The greater bulk of the volume is taken up by useful information relating to the Union of South Africa. The personnel of the Department of Public Health is detailed and that of the medical councils and pharmacy boards of each of the provinces; the principal medical officers of the Department of Defence are named and also the medical and lay members of the Council of Public Health. Medical, dental, and pharmaceutical societies are listed, with their presidents and secretaries. The names, qualifications, and addresses of practitioners (*a*) of medicine, (*b*) of dentistry, (*c*) of pharmacy are then set out first in alphabetical order, and then geographically according to the town of residence. An account of the medical schools, hospitals, and district surgeons concludes that part of the volume devoted to the Union of South Africa. Corresponding particulars are given in respect of the other countries.

It is noted in the preface that the directory has been brought out under great difficulties, since no penalty is imposed on practitioners who fail to notify change of address in South Africa; official registers are thus not always reliable, and it is difficult to trace the movements of practitioners.

Generally speaking, the medical and dental degrees and diplomas of Great Britain and Ireland, which are registrable in Great Britain, are recognised in the Union. But those who hold foreign degrees or diplomas are advised to write to the council or board under whose jurisdiction they propose to practise, in order to ascertain if they are entitled to practise there.

THE PEARL OF FORTUNE.

A Tale of the South Seas. By Lieut.-Colonel T. R. ST.-JOHNSTON, C.M.G. London: Selwyn and Blount. 1925. Pp. 261. 7*s.* 6*d.*

Dr. T. R. St.-Johnston, of the Colonial Civil Service, has to his credit already an interesting volume of South Sea reminiscences, a work on the ethnology of the Pacific Islanders, some verse and fairy-tales. To this rather unusual literary output for a medical man he now adds a sensational novel concerning the discovery on a deserted coral island of a priceless pearl. There were three men only on the island at the time; one found it, one legitimately succeeded to it as a trust, and most of the book is taken up with the attempts of the third, essentially a "bad man," to obtain it, being stimulated not only by ordinary dishonest greed, but by a well-described passion for revenge. The story, while running on familiar general lines, is made interesting by the special knowledge the author is able to display in the *mise-en-scène.* We will not spoil it for the reader by detailing the way in which the interest is sustained by the temporary success and ultimate failure of the villain's designs.

JOURNALS.

QUARTERLY JOURNAL OF EXPERIMENTAL PHYSIOLOGY. Vol. XV., No. 1.—Contributions to the Physiology of Gastric Secretion: I. Gastric Secretion by Local (Mechanical and Chemical) Stimulation, by Robert K. S. Lim, A. C. Ivy, and J. E. McCarthy. The investigations were carried out entirely on dogs provided with gastric pouches or fistulæ. The various kinds or types of fistulæ used by different observers are described and illustrated. Some observations on normal men are included for comparison, and radiographs of the entire stomach pouch after meals are figured. A long historical account of previous observations on local mechanical and chemical stimulation is given with well-documented references to the original papers, and the authors' experimental results are recorded. The mechanism concerned in gastric secretion is discussed and the following working hypothesis is suggested. All stimuli that excite gastric secretion act essentially by increasing the active blood-flow through the gastric glands; the means by which this is accomplished may be quite varied, the motility of the stomach being in some way involved. This view is not held to the exclusion of others, for the enteric reflex may play an important rôle. But since this mechanism does not suffice to explain the secretion to meals in the denervated pouch, and since all attempts up to the present have failed to prove a hormone or humoral mechanism, the authors believe it is better to adopt a hypothesis which offers a common mechanism, and they claim that their observations offer a satisfactory explanation for at least a part of the hypernormal gastric secretion ("hypersecretion") that is observed to occur in cases of pyloric obstruction. The factors concerned in the excitation of gastric secretion are: (1) The cephalic phase, heretofore referred to as the "psychic secretion" demonstrated by Pavlov, which is excited chiefly by the taste, smell, and mastication of palatable food, and by slight or hypnotic suggestion of palatable food. The term "psychic secretion" is rejected because it is not necessarily psychic, as it has been shown to occur in the absence of the cerebral cortex. (2) The gastric phase, in which mechanical and chemical stimuli are effective. (3) The intestinal phase, in which the stimuli are certain chemical substances acting in the intestine as proved in the next paper by the same authors, entitled "The Intestinal Phase of Gastric Secretion." The intestinal phase of gastric secretion, they hold, is due to the action of the products (e.g., peptone, amino-acids, and amines) of digested complex food substances and not apparently to the food in its raw state (meat, carbohydrates, and neutral fat). Water in the intestine stimulates, but not invariably. Gastric secretion may be stimulated from the intestine by a non-absorbable substance—namely, 0·5 per cent. saponin solution. The authors conclude that their observations definitely disprove the specific pyloric or gastric theory as originally stated by Edkins, and maintain that their observations demonstrate that the intestine as a pathway for the stimulation of gastric glands must be considered in an analysis of the factors concerned in the genesis of gastric secretion. In short, the existence of an intestinal phase is proved.—The Effect of Lesions of the Hind- and Mid-brain on Micturition in the Cat, by F. J. F. Barrington. In previous publications the author had shown that two of the reflexes which go to make up micturition do not in the cat arise in the cord but in the brain stem, at approximately the level of a plane through the posterior part of the inferior colliculi dorsally and the middle of the pons vertically. These two reflexes are the only two which produced a powerful and sustained bladder contraction, and to their abolition the suppression of micturition resulting from transection of the spinal cord is apparently due.—Alterations in the Form of Mammalian Erythrocytes in Hypotonic Plasma, by Eric Ponder and W. G. Millar. The authors find that the diameter of the human erythrocyte becomes less as the cell volume becomes greater, and this condition is typical of the behaviour of a balloon-like body. They conclude from their own results, and from those of other observers, that the red cell may be treated as a balloon-like body—i.e., is composed of a membrane containing a fluid or a semi-fluid material, probably a colloidal system, and is not, as suggested by Rollett, composed of a dense stroma in the meshes of which the hæmoglobin is contained.—Action of Adrenalin on the Perfused Fish Heart, by A. D. Macdonald.

Reports and Analytical Records.

"HYPOLOID" BISMUTH METAL.

(Burroughs, Wellcome and Co., Snow Hill Buildings, London, E.C.)

"Hypoloid" bismuth metal in isotonic glucose solution (0·2 g. in 1 c.cm.) has been prepared by Burroughs, Wellcome and Co. as an additional remedy against syphilis. It presents metallic bismuth, now recognised as a definite spirillicide, in the form best suited for intramuscular injection. The isotonic glucose solution allows uniform absorption to take place and practically eliminates abscess formation if the proper technique for intramuscular injection is observed. The required dose is drawn up direct into the syringe barrel by puncturing the rubber cap with the syringe needle and withdrawing the piston to the requisite mark on the barrel. On withdrawing the needle the aperture in the rubber cap closes automatically and reseals the container. The preparation is supplied in rubber-capped bottles 5 c.cm. and 10 c.cm. The commencing dose suggested is 1 c.cm. at each injection.

SQUIBB'S MINERAL OIL, "LIQUID PETROLATUM (SQUIBB)."

(Quelch and Gambles, Limited, 211/215, Blackfriars-road, S.E.)

It is claimed for this Californian oil that it differs in essential respects from other American oils, and is superior to Russian oils. As a mechanical lubricant for internal use the purity of an oil is of importance, and this preparation is stated to be free from inorganic matter, organic sulphur compounds, or injurious hydrocarbons. Colourless, odourless, and tasteless, it has a high specific gravity and a high natural viscosity, the index of lubricating power. The usual dose is one tablespoonful twice a day between meals, one of the doses being taken on going to bed; but the dose can be later increased or decreased according to its effect. For children and infants smaller quantities are, of course, necessary than for adults.

BERINA FOOD AND BERINA MALTED MILK.

(Montgomerie and Co., Ltd., Ibrox, Glasgow.)

We have received from this firm, who are the proprietors of Bermaline bread, a food specially prepared for infants and a preparation of malted milk designed as a diet when necessary for children of a few months old. The ingredients are stated to be whole cream milk, cream of wheat—a short extraction of flour from the wheat berry—and lactose, malt being added in the second preparation. The malt is a product of Scotch barley, and is prepared by the firm at their own maltings. A pamphlet is supplied with both preparations giving careful directions for use, with tables of dosage for the different ages. In this pamphlet a prudent insistence is laid upon the fact that no more food should ever be prepared at one time than is required for immediate use.

TRIVALIN.

(The Saccharin Corporation Limited, 72, Oxford-street, W.)

We have received samples of trivalin capsules and ampoules from the Saccharin Corporation Limited. Trivalin is a combination of caffeine valerianate, cocaine valerianate, and morphine valerianate in certain proportions selected so that the undesirable properties of one drug should be counteracted by the action of the others, with a proportional development of the beneficial properties. It has been used as a substitute for morphine, and medical evidence is forthcoming as to its value as an anodyne. It is supplied in ampoules for hypodermic injection of 1 c.cm., each containing gr. 1/17 caffeine valerianate, gr. 1/12 cocaine valerianate, and gr. 3/10 morphine valerianate, the dose being from ½ to 1 c.cm. once to thrice daily. The capsules are contained in bottles of 12, one capsule to be taken once to thrice daily by the mouth.

Intestinal Infections

resulting from bacterial disturbances can be promptly relieved and controlled by the use of

Dimol

(Dimethylomethoxyphenol)

as described by Captain Ainslie Walker in his brochure

"Intestinal Disinfection"*

The use of intestinal disinfectants has been justly discredited owing to the fact that hitherto it has been impossible to administer anything which was at once efficient and non-toxic.

Take the case of Salol—the best available for many years. The dose is 5 grains—more is unsafe; dissolve this in a quart of water (the average residual fluid of the intestinal tract of an adult) and you get a solution which is too weak to destroy even the most attenuated organisms.

Compare this with Dimol. The dose recommended is 2 to 4 pulverettes—say 3. Each pulverette contains 1 grain Dimol, and Dimol is 35 times more efficient as a bactericide than Phenol, the active principle of Salol; that is to say, in administering 3 Dimol pulverettes the patient is receiving the bactericidal equivalent of 105 grains of Phenol. Moreover, it is not absorbed, being voided with the fæces, unchanged, after doing its work.

When we are able to repeat this dosage four or five times a day without affecting the appetite or digestion, and without action on the mucosa, we can readily understand the excellent results which are obtained by the administration of Dimol in non-amœbic dysentery, rheumatoid arthritis, chronic ulcerative colitis, intestinal putrefaction, fermentation, auto-intoxication, &c.

Testimony from the Tropics.

"I have nothing but unqualified praise for the effects of Dimol in the series of cases in which I used it, including a wide variety of intestinal intoxications from mild but persistent diarrhœas.......to fulminating dysenteries, with passage of large sloughs and great hæmorrhage.......Accept my hearty congratulations on the discovery of what looks like a specific for control of the poisonous flora of the intestine."

—— —— M.B., B.Ch.(Dub.),
29th August, 1922. Medical Officer —— —— *Malay States.*

The efficiency of Dimol in the treatment of many other intestinal infections is conclusively told in the interesting clinical reports which, together with the brochure describing the chemistry and pharmacology of Dimol, will be sent to any physician on application to the sole distributing Agents—

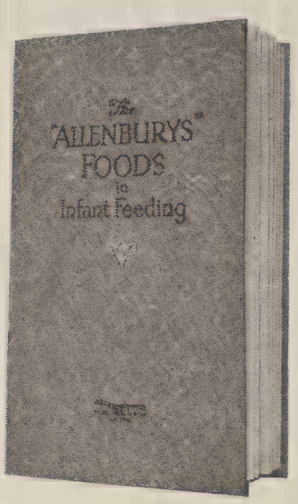
THE ANGLO-FRENCH DRUG CO., LTD., 238a, GRAY'S INN ROAD, LONDON, W.C. 1.
Cables and Telegrams : "Ampsalvas, London." Telephone : Museum 4029.

**The Anglo-French Drug Co., Ltd., will be pleased to send to any member of the Medical Profession, on request, a copy of this brochure together with samples of DIMOL.*

A Misconception

appears to exist in the minds of some members of the Medical Profession in regard to the composition of the 'Allenburys' Foods Nos. 1 and 2.

THESE FOODS DO NOT CONTAIN STARCH



A New Publication

"The 'Allenburys' Foods in Infant Feeding" has just been issued to all medical men on our mailing list. This booklet contains a concise description of the 'Allenburys' Foods and gives full details of their composition and uses.

If you have not received the booklet, or have mislaid it, we shall be glad of the opportunity of sending you a copy.

HEREDITY IN MENTAL AND NERVOUS DISEASE.

THE transmission from parent to offspring of mental and physical characteristics has been accepted as a fact from the beginning of time, but this principle cannot be applied to disease processes quite so simply. The complex living organism is made up of a number of individual entities together composing the whole, and in the consideration of the transmission of qualities the questions at once arise: Does the innate characteristic of the individual persist unchanged and is it transmitted in its unchanged form, or can the characteristic be modified during the life of the individual, and can this modified characteristic be transmitted? The Mendelian laws showed that in comparatively simple organisms, with clearly recognisable traits, the innate characteristic persisted and that the manner of its appearance in the progeny could be mathematically computed. The advent of Darwinism and the theory of sporadic variation further deflected attention from the second possibility, but opinion now shows a trend towards the neo-Lamarckian attitude which affirms that the acquired modification may, under suitable circumstances, be passed on. The Mendelian law is very hard to apply in the complex organism and more particularly in the field of disease. It is difficult, in the first place, to pick out the definite fundamental trait, the unit characteristic; what appears unitary may, in fact, prove to be highly complex. Apart from a very limited group of abnormalities, such as hæmophilia, albinism, and certain familial myopathies, very little in this line has actually been accomplished beyond the establishment of a certain persistence of characteristic in a family tree.

In medicine it has been the custom to introduce the heredity as an ætiological factor in disease, especially in cases where no other definite causative factor is known. The history of pathological research, however, offers many instances where the hereditary influence was once supposed to be the all-important agent, when further advances in knowledge have shown the disease to be one acquired in the life-time of the individual. In such cases, even where the disorder has been definitely proved to be due to an environmental cause, such as the invasion of micro-organisms, the exponents of the hereditary theory merely change their ground and speak of a "diathesis" or a "constitutional tendency." Prof. ABRAHAM MYERSON, in a work reviewed in our columns this week, emphasises this point in relation to tuberculosis. He says:

> "Up till Trudeau's time, in fact right up to the discovery of the tubercle bacillus by Koch, the main factor in the causation of the disease was held to be heredity. There were plenty of families found in which tuberculosis occurred 'generation after generation,' plenty of families found in which all or many of the brothers and sisters had the disease, the same kind of evidence we have to-day for the 'inheritance of insanity.' . . . With the discovery of the infecting organism as a cause of tuberculosis heredity received a knock-out punch; in fact, everyone now loudly proclaims that there is no heredity in tuberculosis, but instead the metaphysical 'predisposition' is acclaimed, and still lingers to obfuscate intelligent thinking."

The real obstacle, as it appears to us, in the way of any advance in our knowledge of the hereditary transmission of disease lies, firstly, in the difficulty of finding a "unit character." There are few diseases which can be so regarded; the majority are symptomatic groupings. Particularly does this apply to mental and nervous disorder, of whose ultimate nature we have at present little accurate knowledge and concerning which it is probable that future research will radically alter our conceptions. Secondly, we do not know how far a certain grouping of symptoms may constitute a biological reaction to certain specific environmental circumstances. Because a certain symptom-complex appears in a national or family grouping it does not necessarily follow that the cause lies within. There is a strong measure of probability in the alternative explanation—viz., that the mechanism of biological adaptation to the environment is producing a similar series of reactions in a number of individuals exposed to the same conditions. Thirdly, we are remarkably ignorant of the laws governing degeneracy, atavism, or simple failure of development. It is a matter of consideration whether a number of the disease entities now recognised are not phenomena of this order rather than disease processes proper.

The progress of *homo sapiens* has been not biological but sociological; it has depended upon his control of and ability to grow at the expense of his environment. The development of man is not reckoned in terms of biology but in terms of his capacity for using materials—the Stone Age, the Bronze Age, the Age of Steam. There has been steady progress in the manipulation of the environmental factor, and it may be that the hope of medical science lies in a further extension of this principle. It is a comforting reflection that the history of medicine shows a steady tendency to eliminate the hereditary in favour of the environmental cause as the knowledge of morbid processes has become more explicit. For it is still a question whether the advance of the human race depends upon the adaptability of man to his environment or upon his capacity for adapting the environment to himself.

◆

THE DYNAMICS OF THE CELL.

IN man's scientific struggle to bring under his direct control all the reactive phenomena exhibited by the animate and inanimate world, progress has been conditioned to a large extent by his power of analysing the concrete basis of his research into particles of ever increasingly minute dimensions, and of defining the laws governing their mutual interaction. Physics and chemistry are approaching each other on the common ground of atomic and molecular dynamics. Physiology, towards which medicine must unceasingly look for a rational interpretation of the problems which confront her, is on her part largely dependent, and ultimately entirely so, on the physico-chemical elucidation of the structure of matter. Without in the least wishing to disparage experimental work done on the whole animal and especially on man—work to which physiology and medicine owe a great and lasting debt—we cannot refrain from emphasising the tendency at present exhibited in physiology to make use of the synthetic method of experimentation. Such a method of study—namely, the study of the functions of an organ isolated from the disturbing and uncontrollable influences of the rest of the body—enables a much more exact determination of the reaction of the individual organ to changes in environment to be made than would otherwise be possible.

Witness the mechanism of muscular contraction and the law of the heart, to mention but two results of fundamental value obtained by this means.

Clearly the individual cell forms a still more particulate field for study—one striking even more deeply towards those basal reactions which are at the root of all natural phenomena. Prof. J. B. Leathes, in the undelivered Croonian lectures for 1923, the last of which we publish to-day, focuses attention in a fascinating manner on the structure of the cell and especially on the part played by fats in the cytological reactions which manifest themselves in such divers ways in vital phenomena. Protoplasm we know to behave as a colloidal solution; when observed under the ultramicroscope particles in Brownian movement can readily be seen. These particles have usually been looked upon as protein aggregates and to account for the high viscosity exhibited by the protoplasm; the colloidal solution has been considered to conform to the emulsoid rather than the suspensoid type. That is to say, the dispersed phase consists of aggregates containing a dilute solution of protein in the interstices between the molecules whilst the continuous phase is a dilute solution of the protein. The cell membrane itself will be composed of any substance which lowers surface tension, this quantity by the principle of Willard Gibbs always striving to become a minimum. Proteins, therefore, will be concentrated in this position, a fact which is readily demonstrated in the surface condensation experiments of Ramsden, or more familiarly in the formation from egg-white of froth which speedily takes on the irreversible rigidity of the meringue. The cell membrane must be looked upon as an intimate and living part of the cell—a portion, indeed, which is in dynamic equilibrium with the constituents of the cytoplasm, and changing its structure with any change in the internal composition of the cytoplasm. The membrane of the resting cell is almost perfectly semipermeable—that is, freely permeable to water but impermeable to the majority of physiological crystalloids. Changes in permeability, however, readily occur. We may mention the decreased electrical resistance of Laminaria cells when transferred from sea water to solutions of pure sodium chloride. Heliotropic curvature in plants is an index of increased permeability of, and, therefore, loss of turgor by, those cells directed towards the light. Excitation is accompanied by increased permeability, whilst narcotics, as would be expected, have the reverse action.

But it is to the presence and state of fat in cells and cell membranes that Prof. Leathes directs special attention. That fat forms an intimate and essential part of the structure of the cell is shown by the fact that in starvation the wasted tissues—adipose tissue, of course, excepted—do not lose a disproportionate amount of fat. This cell fat is found in at least two physical states—namely, as small particles in the cytoplasm and as the lipoid component of the cell membrane. An explanation of the coexistence of a continuous lipoid membrane and dispersed fatty aggregates may, perhaps, be found in the study of the behaviour of fatty substances when forming films at an air-water interface. The physical properties of substances in this condition are very different from those of the same substance in bulk. These properties have been studied by Langmuir and by Adam. By means of an ingenious arrangement it has been shown that unimolecular films are formed when fatty acids spread on water, the molecules being oriented in a definite direction perpendicular to the surface. The polar group of the molecule is attached to the water, and the kinetic energy of the molecules of the latter is imparted to a certain degree to the molecules of the film causing a much greater intermolecular distance than is exhibited by the same substance in mass at the same temperature. The films may exist in two main forms, either in the condensed state, when the substance is in reality a two dimensional solid or liquid, or in the expanded state, a two dimensional gas. Prof. Leathes has extended this work in a study of the films formed by lecithin and by cholesterol, lipoids which enter so ubiquitously into the formation of the cell membrane. The former is found to form a highly expanded film, the latter a condensed one. Indeed, the myelin outgrowth from the surface of lecithin in a watery medium is an expression of this tendency to form an expanded film. Clearly any interpretation of cell structure which fails to take into account the extraordinary properties of unimolecular layers of fats and lipoids must inevitably be short-lived. Prof. Leathes points out that it is impossible to account for the properties of the cell substance by the aid of protein alone, and "if in order to understand the physiology of cells it is necessary to take into account interfacial phenomena it is fats rather than proteins that we must look to to provide the interfaces."

We commend the lectures to the close study of our readers. It is such work as is embodied in them which bids fair to expose the secrets of cell life, and so give us an ever clearer and more valuable insight into the nomocracy of vital phenomena.

◆

THE CONTROL OF VACCINES: AN APPEAL TO PARLIAMENT.

We feel confident that the medical profession will support the appeal we make to Members of Parliament to pass the Therapeutic Substances Bill at an early date. This useful little measure, which now awaits a second reading in the House of Commons, has already attained a third reading in the House of Lords three times—in July, 1923, in May, 1924, and in March of this year. It seeks to secure the standardisation and purity of certain substances, such as vaccines, sera, salvarsan, insulin, and pituitary extract, which are incapable of analysis by ordinary chemical process.

In the field covered by the Bill, England at present lags behind other civilised countries. The United States, France, Italy, Spain, Germany, Norway, and Sweden submit the manufacture of these substances to the most rigid inspection. Denmark has gone even further and insists that all such preparations be made in State laboratories only. There is no occasion to go thus far in England where private firms have established so high a standard of manufacture. But undoubtedly it is urgently necessary to set up and enforce tests of purity and potency. Fatal cases have occurred because the practitioner has no certain guide to the strength of some of the new and indispensable remedies which scientific research has placed in his hands. Some of these substances are highly poisonous unless prepared in properly graded quantities. In practice a doctor acquires with immense care and caution an experience of the activity of pituitary extract supplied by a particular firm. If accident or emergency compel him to depend upon the product of another firm, he is working in the dark for want of the uniformity which this Bill is designed to create. His accustomed prescription may prove equally dangerous because on the one hand it has not the efficiency upon which he is relying, or because on the other hand its unsuspected strength amounts to an overdose. At present there is nothing to prevent this country from being flooded with preparations which the other countries named above have already rejected for bad quality. There is nothing to ensure that imported preparations shall conform to the careful standards which British manufacturers have severally established for themselves. If we delay much longer and if an international convention is signed before any official body in this country is authorised to standardise British products, we shall find that American and Continental manufacturers will be able to sell their products here while British products will be refused in America and on the Continent.

The Bill contains adequate safeguards and will secure uniformity of standards of authenticity and activity. The Minister of Health, the Secretary for Scotland, and the Minister of Home Affairs for Northern Ireland, acting together as a joint committee, are directed to consult an advisory council, which will include representatives of the Medical Research Council, the General Medical Council, the Pharmaceutical Society of Great Britain, and the Institute of Chemistry of Great Britain and Ireland. The Bill has suffered, it would seem, not only from its rather unhappy title, which is neither attractive nor explanatory, but also from its non-contentious character. Had it been more controversial, it would have excited more discussion and its purpose would have been more widely understood. It has aroused no hostility either from the medical profession or the manufacturers. The latter, indeed, as we stated when discussing the proposals in these columns in 1921,[1] are strongly in favour of the scheme because it protects both themselves and the public from the activities of those who are inefficient or dishonest. The Bill involves no bureaucratic extravagance and no horde of new officials. The testing will mainly be done by the manufacturers themselves, and the supervision will be undertaken by the Medical Research Council. Let it be clearly understood that, until this Bill is passed into law, lives are daily being needlessly endangered. The matter must not be left till the evidence at an inquest creates a sensation for the public and a panic for patients. The House of Commons will not wish to show itself indifferent to the perils of the present position.

◆

THE INTER-STATE POST-GRADUATE ASSEMBLY.

THE Inter-State Post-Graduate Assembly of America, directed by the State Medical Association of that country, is visiting the British Islands during June. Opportunity will be taken to hold the Annual Congress of the Association on this side of the Atlantic, and the inaugural ceremony will take place on June 2nd at 9.30 A.M., at the Wigmore Hall, London, W., when the Duke of York will be in the chair. A reception will be held on the evening of the same day at Lansdowne House by the Princess Wiasemsky and Mr. Gordon Selfridge. The banquet in connexion with the Assembly has been arranged for Friday, June 5th, and by the permission of the Corporation of London will be held in the Guildhall at 8 P.M., Dr. Charles H. Mayo, of Rochester, Minnesota, presiding, while the chief speaker will be Mr. Neville Chamberlain, Minister of Health. On the following day the American Ambassador and Mrs. Houghton will give a reception to the Assembly at Crewe House.

The visit to London is part of an itinerary, which includes also Edinburgh, Dublin, Leeds, Liverpool, Manchester, Newcastle, Belfast, and Glasgow, and at all these centres arrangements of a social nature have been made. The general programme of the tour is in the hands of Mr. Philip Franklin, F.R.C.S., 27, Wimpole-street, London, W. 1.

Annotations.

"Ne quid nimis."

TREASURY GRANTS TO UNIVERSITIES.

THE impartial distribution of the annual contribution from the Treasury among the universities and university colleges applying for State help is a formidable task. For several years it has been entrusted to the University Grants Committee to assess the relative urgency of the needs of some 50 institutions. The personnel of the committee consists of Sir William McCormick (chairman), Sir William Bragg, Sir Dugald Clerk, Sir Wilmot Herringham, Sir Arthur Keith, Sir Frederic Kenyon, and Sir Stanley Leathes. In academic circles the annual report of this representative committee is studied with at least as much anxious attention as the National Budget. The report for 1923–24,[1] recently issued, includes as usual, besides a table of the recurrent and non-recurrent grants allocated, full statistics of the institutions subsidised. Particulars as to number and age of admission of new students, the number of full and of part-time students, the proportion of students as to those of each sex in each faculty, and the number of degrees and diplomas obtained, as well as summaries of income and expenditure, are clearly set out in appendices. Incidentally, full-time students working in the faculty of medicine (including dentistry) throughout Great Britain amount to 10,864—8866 men and 1998 women—and even these big numbers do not indicate the total, since Guy's Hospital Medical School is not among the applicants for State aid. The corresponding figures for 1922–23 are 11,866 (9498 men and 2368 women), so that some diminution is shown.

A table that appears this year for the first time shows the salaries of the full-time teaching staffs at institutions other than Oxford and Cambridge. The salaries of the 623 professors average £977, and range from £550 (nine posts) to £2000 (seven posts). It is noted that of the 55 professors receiving salaries below £800, 36 work in the University Colleges of Exeter, Nottingham, Reading, and Southampton, and in the Durham colleges, and that in most institutions the minimum salary for a professor is £800 a year. The figures do not, the committee point out, indicate a very generous national conception of the rate of pay suitable to the highest class of academic worker; but they do not consider it desirable that any attempt should be made to lay down a uniform minimum salary for this or any other grade of university post in all places and in all subjects. Universities differ from one another in size, wealth, and standing, and a chair at one centre may carry a heavier load of work and responsibility than the corresponding chairs at others; again, different subjects, for reasons which may have little connexion with their intrinsic importance, occupy different places in the scale of values that reigns in the academic market. No examples are cited, but it is obvious that the highest professorial figure (£2000) represents a scale of pay below which it would be impossible to induce members of the medical profession to give up lucrative consulting practice in London for full-time service. The general systematisation of salaries would not, in the opinion of the committee, benefit university education and would tend to impede that free circulation of teachers through various institutions which is a valuable asset in academic life. However, the problem of the remuneration of the senior member of the lecturer grade is regarded as an urgent one, and a suggestion is made that individual service might be recognised by preferment to a special post which might be created for and need not necessarily outlive the holder.

---

[1] University Grants Committee. Report including Returns from Universities and University Colleges in receipt of Treasury Grant. Academic Year 1923–24. London: H.M. Stationery Office. 1925. Pp. 44. 3s. 6d.

During the year under review the committee paid a series of visits to institutions receiving grants, their previous visitation having taken place in 1919–20. They conclude that while real progress has been made in the intervening period, improvement is urgently called for as regards conditions of service of staff, and the provision of libraries and of material equipment in such departments as already exist, and that the responsibility for maintaining new departments should not be undertaken until the existing ones are put on a satisfactory basis. The social needs of students, especially more extended facilities for life in suitable residential halls, should also receive early consideration. These needs are recognised by the majority of the institutions and depend only upon increased financial resources. The increased grant-in-aid voted by the Treasury for the academic year 1925–26 is noted with satisfaction by the committee, who will have at their disposal £1,550,000 for that year in place of £1,242,570, which is the amount voted for the year 1924–25. The report throughout shows unmistakable signs of care to consider the highest interests of university education in this country from all possible points of view, and the committee deserve the gratitude of the public as well as that of the academic world for their labour.

THE SEROLOGICAL DIAGNOSIS OF SCARLET FEVER.

In 1918 W. Schultz and W. Charlton stated that if serum taken from a normal person or from a convalescent case of scarlet fever was injected intradermally into the skin of a person with a bright scarlet fever rash there appeared after a time a complete blanching of the rash at the site of injection over an area from half an inch to a few inches in diameter. W. Mair[1] showed that Schultz and Charlton were mistaken in their claim in so far as related to the serum of a normal person who had not been rendered immune to scarlet fever. More recently the serum of horses immunised by means of the hæmolytic streptococcus, thought to be the cause of scarlet fever, has been used in the same manner to test its rash-blanching value. Quite apart from the question of the serum treatment of scarlet fever, this blanching power of the serum may aid in the differentiation of scarlet fever from rashes which resemble that disease. With this object a number of workers have been engaged in testing the value of this phenomenon in scarlet fever and to a lesser degree in other rashes. There is no practical method of standardising this serum, and hence variation in the blanching power of different sera is to be expected, and actually the blanching is found to vary. Yet the variability of the blanching reaction does not appear to be wholly due to want of standardisation, for the same serum can produce varying degrees of blanching in different individuals. Further, it occasionally happens that it fails to produce any reaction in a case that appears to be clinical scarlet fever, though reacting well in others. In such instances even the expert clinicians will remember their frailties and be prepared to admit that after all the serum test may be the better guide. There may be other explanations of this failure. For example, if a rash has been established some days it is possible that it might blanch less readily, and if it was a pronounced one perhaps not at all. This point has not yet received the attention that it no doubt will.

The Schultz-Charlton reaction varies in its intensity, in the size of the blanched area, in its time of appearance, and in the time it lasts. Further, it may vary with the amount of serum introduced and, as would be expected, it varies in the same person with differing dilutions of serum, though not always so if the dilution be not very great. The intensity of the reaction varies from the complete local blanching of the rash to a faint fading which is difficult to see. Complete blanching is common enough, but it is also quite usual to see in an easily observed and partially blanched area the punctæ of the scarlet fever rash. When human serum was used it was found that the size of the area varied from about half an inch in diameter to two inches, but the quantity introduced was from 0·7 to 1 c.cm. The horse serum, in dilution, now being used in doses of 0·2 c.cm. results in a blanched area, or partially blanched area, varying from about half an inch in diameter to one inch. The interval from the time of injection to the commencement of the blanching is usually from 12 to 24 hours, but it may unusually be postponed for even 48 hours, and has been observed as early as 3¼ hours. The blanching usually remains clearly visible for about two days, though punctæ commonly reappear within the area earlier. On the other hand, the blanching may remain until the rash disappears, and even afterwards may show as a non-desquamating area surrounded by the usual pin-point and pin-hole desquamation. Further, it occasionally happens that the rash fades quickly without a blanching reaction arising.

This serological test has been applied to a number of other rashes, such as serum rashes, measles, rubella, influenza rashes, and other erythemata without blanching arising. The test is therefore a promising one from the point of view of differential diagnosis, but more observations are desirable to prove, if it can be proved, that the reaction occurs in scarlet fever only.

THE FUNCTIONS OF THE HOME OFFICE.[1]

A scheme has been set in motion for publishing accurate and authoritative information in an accessible form concerning the great Departments of State. The volumes are to be termed the "Whitehall Series," and it opens with Sir Edward Troup's book. If the excellent precedent thus formed is followed the series will be useful to all who are interested in the government of the country, and the number of people who to-day try to get an intelligent grasp of the principles upon which they are legislated for is an increasing one. Among these people are Members of Parliament themselves who do not take their seats, either in the Upper or Lower Chamber, as jurists or as administrators, and who are for the most part—we say it respectfully—as ignorant as many of us of how things are done at Whitehall. Civil servants, again, should find in these volumes information about other offices than their own, and municipal workers, students of administrative methods, and journalists will find them useful books of reference. How often do most of us want to know in whose jurisdiction a certain activity lies, and where to find detailed information concerning it? Sir Edward Troup, who was Permanent Under-Secretary of State for the Home Office from 1908 till 1922, is brief and modest, but we are glad to see that space has been made to include a history of the origin and development of the powers and functions of the Home Office, for over and over again it happens that the meaning of the legislation of to-day becomes clear when the conditions which gave rise to it, now forgotten, are brought to light. To a medical audience the chapters on police administration, on prisons and institutions like Borstal or Broadmoor, on the control of immigration and the question of aliens, and especially on the Factory Acts and workmen's compensation will be particularly welcome. We are glad to see that Sir Edward Troup states definitely that the time has arrived for a further consolidation of the Factory Acts, for we consider that the delay in introducing the Home Office Bill on the subject is most unfortunate. All who are in touch with the administration of these Acts know that the law requires amending, simplifying, and strengthening. Other sections of particular interest to our readers will be those dealing with intoxicating liquors and dangerous drugs, and an informing chapter on public morals and public amenities.

---

[1] The Home Office. By Sir Edward Troup, K.C.B., K.C.V.O., Permanent Under-Secretary of State in the Home Office, 1908–1922. London and New York: G. P. Putnam's Sons, Ltd. Pp. 267. 5s.

The succeeding volumes of the series, as announced, are as follows: "The Ministry of Health," by Sir Arthur Newsholme; "The Admiralty," by Sir Oswyn Murray; "The India Office," by Sir Malcolm Seton; and "The Post Office," by Sir Evelyn Murray. The series is issued under the general editorship of Sir James Marchant.

AN UNUSUAL CASE OF PREGNANCY.

MANY cases of pregnancy have been recorded in which the woman was unaware of her condition, usually through sheer ignorance, until the moment of parturition, but it must be rare for a married woman with three children to go to term in a fourth pregnancy without any knowledge of her state, as occurred in a case reported by Dr. R. Beckers, of Brussels, in *Bruxelles Médical* for April 19th. The woman was 30 years of age and had three children, aged 3, 4, and 5. Her three pregnancies and confinements had been perfectly normal and there was no history of any gynæcological complaint. She woke one morning to find the sheets soaked with a clear and copious vaginal discharge and 24 hours later she was delivered of a living child weighing about 5½ pounds, labour being associated with the expulsion of a considerable excess of amniotic fluid. Inquiry into her history revealed that she had menstruated regularly each month for the usual number of days, that she had felt no movements, nor had she suffered from any malaise or digestive disturbance. The larger size of her abdomen had not attracted her particular attention since previous pregnancies had left the walls lax and she attributed any swelling to her habitual constipation. Her breasts had shown no alteration from the state in which they had been left by previous pregnancies. Dr. Beckers examined the patient about 20 hours before delivery and he found a uterus enlarged to the size expected at about five or six months, with very exaggerated ballottement of a fœtus, no movements of which could be felt, nor could any fœtal heart sounds be heard. The case is of interest both from the obstetric and legal points of view. It adds another to the list of cases where losses of blood at monthly intervals have occurred during pregnancy, which losses were indistinguishable from the phenomena of normal menstruation; and the hydramnios which was present could not be accounted for by any trouble in previous confinements, by any signs of cardiac or renal disease, the Wassermann reaction being negative. From the legal point of view the existence of pregnancy in a comparatively intelligent multipara without her knowledge is important in view of the responsibility of the doctor called in to deal with the first symptoms of labour in such a case.

APPLETON'S.[1]

REMINISCENCES of a great publishing house are always of interest, and those of the house of Appleton have a special interest for the medical profession owing to the amount of medical and surgical literature which emanates from that source. The founder of the firm was Daniel Appleton and the book business was at first merely a small section of a general store mainly devoted to dry goods. This was in 1825. By 1830 the general store had become solely a bookstore and in 1831 the first book was published. This was some 3 inches square, was entitled "Crumbs from the Master's Table," and from a reproduction, as an illustration, of two pages we see that it consisted of devotional commentaries upon certain texts of scripture, and was not, as stated, made up entirely of verses from the Bible. In 1832 appeared the book which was in a way the forerunner of the host of medical books hereafter to be issued, called "A Refuge in Time of Plague and Pestilence," being a devotional commentary on the 91st Psalm which the writer considered as entirely relating to plague. It appeared at an opportune time, for cholera was then devastating the country. The present head of the house, William Worthen Appleton, is the grandson of the founder, who seems to have had an innate flair for publishing. For the founder recognised the charm of Lewis Carroll's "Alice in Wonderland" at its first appearance and bought a number of sheets for publication in the States. He also brought out the "Uncle Remus" stories, and no doubt reaped the rewards of his perspicacity in both instances. To medical men his chief service was the part which he played in the publication of Osler's "Principles and Practice of Medicine," but the account given by Mr. Overton of the transaction is not altogether in accordance with that given in a letter from Osler himself, to be found in Prof. Harvey Cushing's biography, reviewed in another column of this issue. Appleton was, in addition, the publisher of Herbert Spencer's writings in the United States, and Mr. Overton gives some amusing letters from Spencer to his publisher which well show the wretched valetudinarianism of the former and his perpetual sense of injury. Thus he complains bitterly of his health: "You in common with most people do not understand what a thorough invalid I am. At the end of last August (the date of the letter is May 24th, 1901) I had rather too long a conversation with a gentleman who came to see me at Bepton, and the result was that I have never been up to my low level since; I have not taken a drive since last August, and for six months was never out of doors until a fortnight ago, when an experiment in a bath-chair did me great harm." For all this Spencer died in his eighty-third year. Mr. Overton's brochure will appeal to all lovers of books.

THE DOUBTFUL VALUE OF IODINE IN TUBERCULOSIS.

Two papers on the treatment of tuberculosis with iodine have appeared recently in the French medical press. They are typical of two widely different mentalities and schools of therapeutics. The one may be said to represent faith without reason, the other reason without faith. The first school is represented by the paper written by Dr. S. Bonnamour and Dr. P. Delore in the *Journal de Medécine de Lyon* for April 5th. The authors' presentation of their thesis is crisp, dogmatic, and admirably parsimonious in words. They state that iodine may be given by the mouth, by intramuscular injection, by inhalation, or by intravenous injection. It may be given in large or small doses, and a variety of preparations, ranging from the simple tincture to the semi-mystic "colloidal electro-chemical" preparations, may be tried. The authors then proceed to state the indications which are perfectly simple. If the disease is chronic, stationary, or, better still, in the pre-tuberculous stage, iodine is indicated. It is contra-indicated in those cases which do not terminate in recovery by natural means, "natural means" being a euphemism for freedom from medicamentary interference. In this paper there is no account of the rationale of treatment with iodine; even that notorious guinea-pig which has recovered from tuberculosis under a certain treatment is not dragged into the discussion. As for the clinical results of the authors' treatment, we learn nothing until the last three lines of their paper is reached, when we read that their results will be published in a later paper. Very different is the quality of the second paper, published by Dr. S. I. de Jong and Dr. J. Christophe in the *Presse Médicale* for April 8th. Before the war they carried out experiments on guinea-pigs which were infected with tubercle bacilli and treated with iodine in different ways. It was found that the action of iodine on the tuberculous processes was, if anything, detrimental. After the war, the authors tested the action of iodine on

---

[1] Portrait of a Publisher; and the First Hundred Years of the House of Appleton. By Grant Overton. London and New York: D. Appleton and Company. 1925. Pp. 96. 3s. 6d.

40 patients suffering from pulmonary tuberculosis. They first gave iodine by the mouth in the form of the tincture, the dose of which was gradually increased. They found that nausea and gastric disturbances contra-indicated this procedure, which they abandoned in favour of intravenous injections of iodine methylate of hexamethylenetetramine. In most cases this treatment was well tolerated and could be continued for months with impunity. But as many as nine patients suffered from hæmoptyses during this treatment, and in 30 cases there was no evidence of even transitory improvement as a result of the injections. Only in ten cases could any improvement be noted, and in none of these ten did the improvement last long. In no case did tubercle bacilli disappear from the sputum or the temperature show improvement. A carefully documented report like this may not be palatable literature for the enthusiastic therapeutist who wants to be "up and doing," but it is bound to command the respect of all who consider therapeutics a science stripped of empiricism.

MALARIA UNITS IN PALESTINE.

MALARIA has played an important rôle in the historic development of Palestine, where the disease is attracting the close attention of the present Zionist organisation. In Palestine the malaria season coincides with the breeding of the main species of anopheles, commencing at the end of March and lasting to the end of December. Thus there are but three short winter months when the infection is quiescent. The Malaria Unit has spread its activities, the most important of which were the control demonstrations designed to establish the possibility of reducing malaria in Palestine on a large scale at a low cost. These demonstrations are described in the annual report for 1923 of the Malaria Research Unit at Haifa, which is maintained by the American Joint Distribution Committee in coöperation with the Government of Palestine. Simultaneously with these demonstrations the unit was enabled to amass a considerable amount of useful information regarding the prevalence of malaria in different parts of the country and to pay attention to the commoner species of anopheles. The permanent elimination of breeding places of anopheles has also been aimed at. In some cases coöperative drainage undertakings were stimulated by contributing to the communities part of the cost in money or in labour. The laboratory of the unit has contributed greatly to the success of the work. It examined thousands of blood-films for the determination of blood-indices, and in studying other special problems it has proved itself an important part of the general organisation of the unit.

PROTECTION OF UNDERGROUND WATER.

THE Ministry of Health has published a report of the Advisory Committee on Water[1] setting forth the conclusions of a subcommittee upon the protection of underground water-supplies against depletion and pollution. There is happily an ever-growing demand for a higher standard of purity in water-supply. There is also, it need hardly be said, an ever-growing demand for quantity in supply. The expansion of urban areas and the requirements of baths, sanitation, and street watering have multiplied the consumption of water per head of the population. We can no longer afford waste or want of coördination. We have, it is true, the Public Health Acts provisions as to sewage and nuisance, the Rivers Pollution Acts (hard as they are to apply), and the by-laws of local authorities as to cesspool construction and proper scavenging. But, as the subcommittee points out, the general provisions of the law seem directed towards protecting surface water rather than underground water. Science as applied to sanitation has evolved improved methods of sewage purification and refuse disposal. But science as applied to the engineering side of mining and of water-supply has also evolved improved methods of large-scale pumping. There is evidence, especially in colliery districts, that new perils assail underground water-supplies. The subcommittee describes the kind of case it has had to consider. Heavy pumping at a colliery opens out fissures and draws in sea water, thus increasing the proportion of salt in the well of a water company nearer the sea. An East Kent colliery pumps water from strata below the chalk and discharges it on the surface in large quantities; the result is that the water finds its way back to the underground sources of water-supply in a contaminated state. Another colliery elsewhere pumps huge quantities of water to waste within a water company's statutory limits. In Flintshire lead-mining operations have tapped the source of St. Winifred's well at Holywell, drying up what was part of the local authority's source of water-supply as well as destroying the virtue of a place of ancient pilgrimage. Such examples might be multiplied. A casual glance through our local Acts of Parliament will discover cases where the needs of water-supply have required protection in the grant of fresh powers to public undertakings. Meanwhile the common law of the ownership in underground water is so remarkably unfair, the contamination of water by adjacent operations is so difficult to prove, and the cost of litigation is so high, that fresh legislation certainly seems necessary.

The recommendations of the subcommittee may be summarised thus. The Ministry of Health should have power to schedule areas (after due notice and local inquiry) for protection. Inside those areas no fresh wells (except for domestic or farm purposes) and no fresh mine-shafts should be sunk without a permit from the Minister, who in mining cases would act in consultation with the Mines Department of the Board of Trade. To prevent pollution, all statutory water undertakings should be given the powers (which some already possess by local Act) of protecting their supplies by acquiring adjoining land, limiting its use, or requiring particular measures of drainage. Compensation would be given to interests injuriously affected. The Ministry of Health should have power to obtain returns of water pumped to waste. The borings of mining companies might be tubed and made water-tight. The specific strengthening of Sections 61 and 62 of the Waterworks Clauses Act of 1847 is recommended, and also (as already indicated) the general application of clauses now found only in local Acts, together with the comprehensive consolidation of the whole public law of water-supply. Some legislative action certainly appears essential. The problem of reconciling conflicting interests is not more difficult than that which Parliament managed to solve in the Mines (Working Facilities and Support) Act of 1923.

ORIENTAL SORE IN A NEW CENTRE IN PALESTINE.

IN the *Archiv für Schiffs- u. Tropen-Hygiene* for March Dr. A. Dostrowsky, of the Hadassah Medical Organisation in Jerusalem, tells us that Jericho is the only endemic area of Oriental sore (cutaneous leishmaniasis) so far known in Palestine, but reports that another has been found at Artuf, a small Jewish village of 114 inhabitants, 941 feet above the sea, on the other side of the Judæan hills from Jericho, with quite different flora, fauna, and physiography. It is two hours by train from Jerusalem. The resident doctor saw the first case in the summer of 1923, in a man who had not left the village for eight years. Altogether ten cases were seen, of all ages, and in only four families; in one family five children were attacked. How are such cases spread? Dr. Dostrowsky suggests it is by phlebotomi. The village had hardly known these flies till 1923, when, in the summer, they became a plague. The villagers live in two-storied houses, their cattle on the ground floor. That only four houses were infected is to be correlated with the known habits of phlebotomi which gather, apparently without reason, in one house and leave the next alone; bugs and fleas distribute themselves more evenly. The sores are not spread by auto-infection through scratching, for even if the patient is lousy (many of them are very poor) and scratches freely, the later sores are, like the earlier, found only on the uncovered surfaces. The carrier, if any, of this outbreak cannot be traced; no stranger came to the valley in 1923. Cases are frequently seen in Jerusalem, but only in visitors; never has a patient who has returned to his home there been known to infect his relatives. Dr. Dostrowsky's view that Oriental sore is spread by an insect, most likely by a phlebotomus, has a good deal to support it.

INTERNATIONAL MEDICAL FELLOWSHIPS.

ONE of the most valuable gifts which an advanced scientific worker, whether at the bedside or in the laboratory, could hope to receive would be the opportunity of a period of intimate association with those engaged in studying similar problems in other countries. Until recently this privilege was hardly available except by private arrangement, but some three years ago the Rockefeller Foundation of New York allocated a fund of $50,000 to the Medical Research Council for the provision of Fellowships of Medicine tenable in the United States upon the award of the Council during a period of three years.

The Council, in giving public notice of these Rockefeller Medical Fellowships, announced their intention to award the Fellowships, in accordance with the desire of the Foundation, to graduates who had received training in research work in the primary sciences of medicine or in clinical medicine or surgery, and were likely to profit by a period of work at a university or other chosen centre in the United States before taking up positions for higher teaching or research in the United Kingdom. The first four Fellows appointed under the scheme worked in the United States during the academic year 1923–24. Dr. J. C. Bramwell was engaged in clinical and laboratory studies of diseases of the cardio-vascular system, chiefly with Prof. Erlanger at Washington University, St. Louis. Mr. N. M. Dott did clinical and experimental work in neurological surgery, with Prof. Harvey Cushing at the Peter Bent Brigham Hospital, Boston. Dr. Helen Ingleby worked with Dr. Adolph Meyer in the psychiatric clinic at the Johns Hopkins Hospital, Baltimore, on the morbid histology of the central nervous system. Dr. H. K. Ward was engaged in experimental work on the treatment of tuberculosis and on other subjects, chiefly with Dr. Zinsser in the Department of Bacteriology, Harvard Medical School, Boston. For the academic year 1924–25 Rockefeller Medical Fellowships were awarded to Mr. R. K. Cannan, Dr. J. J. Conybeare, Dr. J. R. Learmonth, Dr. Ethel M. Luce, Dr. J. W. McNee, and Dr. W. Robson. Full particulars and forms of application for Fellowships for the academic year 1925–26, which will shortly be awarded, are obtainable from the Secretary, Medical Research Council, 15, York-buildings, Adelphi, London, W.C. 2, with whom applications must be lodged before June 10th, 1925. Each Fellowship has the value of not less than £350 a year for a single Fellow, with extra allowance for a married Fellow, payable monthly in advance; the terms are elastic, so that special circumstances of individual candidates can be taken into account. Travelling expenses and some other allowances are made in addition.

The recent announcement that the Commonwealth Fund of New York has decided to establish 20 annual Fellowships at American universities for British graduate students is also welcome. The amount of these Fellowships will probably be about £600 a year for three years and the holders will be appointed by a committee of award. The student will be allowed to select the university in which he wishes to study, but not more than three Fellowships will be awarded at any one American university. Further details have not yet been announced, but since the members of the British Committee of Award include Sir Hugh Kerr Anderson, F.R.S., it is certain that the claims of medical graduates will receive a sympathetic hearing. These last-named Fellowships are largely made possible by donations amounting to over £5,000,000 from Mrs. Stephen K. Harkness to the Commonwealth Fund, towards the promotion of a closer understanding between Great Britain and the United States. It would be difficult to imagine a better way of achieving this object.

THE INFANTS HOSPITAL.

THE festival dinner of the Infants Hospital, Vincent-square, was held last week, by permission of the Corporation, in the Guildhall of London, under the presidency of H.R.H. Prince Henry, who made an excellent speech in proposing the prosperity of the institution. He pointed out that the hospital was the first of its kind to be established in Europe, and he appealed for the sum of £25,000, required for the further expansion of work whose objects included the placing on a scientific basis the management of infants up to 5 years of age, the treatment of nutritional diseases, and the investigation of the causes of infantile mortality. His Royal Highness stated correctly that some 40 per cent. of our infantile mortality is preventable, and amusingly concluded by pointing out, without intention, one of the main difficulties in connexion with prevention. He said that he had not known until he visited the Infants Hospital how complicated the feeding of infants is; but the general public, when for this reason or that the natural methods of sustenance fail, are in the same plight. Part of the work of the Infants Hospital is to spread knowledge. Mr. J. Gomer Berry, the chairman of the Hospital, spoke of the growing prosperity of the institution, of the attraction which it exercised for patients all over the country, and of the value of its researches, which were placed at the disposal of every doctor. He announced the gift from the Prudential Assurance Company of £1000 for the cost of an X ray installation, accompanied by a promise to maintain five beds. Lord Birkenhead proposed the medical and nursing staff of the Infants Hospital, and spoke of the movement which it represented as reflecting exactly the growth of our national responsibility for the physical welfare of the nation. Dr. Eric Pritchard, the medical director, having replied, it was announced that the donations had reached £15,000, about one-third of which sum was represented by the endowment of nine cots. We understand that a considerable further sum has since been received, so that the authorities of the Hospital can recognise that the stamp of public approval has been put upon their endeavours.

THE MEDICAL CAREER OF JOHN KEATS.

Sir William Hale-White, by his paper on the Medical Career of John Keats, delivered as the annual oration of the Medical Society of London on May 11th, added a valuable contribution to our knowledge and love of the man who is "numbered among the inheritors of unfulfilled renown with Catullus and Marlowe, with Chatterton and Shelley, whom we mourn as doubly dead in that they died so young" (Osler). Much has been written on Keats, but touching his career as a medical student surprisingly little, and that has often been wrong. Known to have been a surgical dresser, it is usually assumed that he was unqualified. But the medical profession has complete justification for regarding him as definitely one of us, and Sir William Hale-White exhibited on the epidiascope the actual pass list of the Society of Apothecaries as published in the "London Medical Repository," 1816, containing the entry: "John Keats, Wilston, Edmonton."

Keats was born in October, 1795, and in 1803 went to a school kept by John Clarke at Enfield. He left school at the age of 16 to begin his apprenticeship to Mr. Thomas Hammond, surgeon, of 7, Church-street, Edmonton. Thomas Hammond's house, "Wilston," is at the present day named "St. Winifreds," and is still occupied by a medical man. Close by the house is a little cottage in which Keats and his fellow apprentice were housed, but this tiny building has recently been condemned, and will soon have disappeared. Keats was articled to Hammond for five years, but at the end of his fourth year he left to "walk the hospital" at Guy's, and his name is inscribed in the register of physicians' and surgeons' pupils and dressers in 1815. The notes which Keats took when attending lectures on anatomy and physiology have been preserved in a small grey-green notebook in boards with frayed edges at present in the Dilke Collection at the Hampstead Public Library. The orator showed on the screen a facsimile of that notebook, and he expressed his gratitude to the mayor of Hampstead for allowing him to have the facsimile made. Following the name "John Keats" on the inside cover are 28 pages of neat well-spaced notes on descriptive anatomy, notes which must obviously have been made at the writer's leisure. These notes occupy the left-hand pages, while the right-hand pages are filled with closely written, often misspelled records of physiology lectures, which sometimes run over into the margins of the anatomy notes. This contrast has led some authorities (as Sir Sidney Colvin) to say that Keats obtained some other student's anatomy notebook and used it for his own physiology notes, but Sir William Hale-White considered that all the writing came from the same hand, the varying circumstances of time and pen accounting for discrepancies. The anatomical notes were clearly made before the physiological ones, and surgical annotations are often added. The course in physiology as described in the notebook consisted of 12 lectures, the ninth of which Keats apparently did not attend, each on a separate subject. The lectures, Sir William Hale-White said, were good, up to date, and practical, each being illustrated by applications to medicine and surgery. Who was the lecturer? Keats does not name him, but six times in the anatomy lectures and 14 times in the physiological he refers to a "Mr. C." The *Medical and Physiological Journal* for the years 1814–15–16 gives the names of four lecturers in the combined schools of St. Thomas's and Guy's, all of whose names begin with "C"—Astley Cooper, Henry Cline, Curry, and Cholmedley. Curry and Cholmedley lectured on medicine alone, and can therefore be excluded, but both Cooper and Cline taught physiology. Cline's series of lectures, however, began with the muscles of the head, and as Keats's notes do not treat of these we may assume that the lecturer was not Cline, but Mr. (as he was then) Astley Cooper. And the evidence is strong that the anatomical notes were also derived from Astley Cooper. Sir William Hale-White, comparing some of Astley Cooper's lectures, published in 1824, with Keats's notes, found such similarities as follows: Astley Cooper—Koskiusco had his sciatic nerve wounded by a pike; Keats's notes—Patient K. had sciatic nerve wounded by a pike. The evidence is therefore conclusive that the whole of Keats's notes are from lectures by Astley Cooper. Lectures were a very important matter in those days, but the most dramatic part of the student's life was to attend operations, an unpleasant business. The orator quoted South's description of the scene in the operating theatre—the heat, the foulness, the screams of the wretched patient, and the struggle of students for front places when the operator was popular, as Astley Cooper was. Such scenes must have had a horrifying effect on the sensitive poet, and Astley Cooper, a true friend to his students, seems to have noticed Keats among the crowds who sat at his feet, and to have put him under the special care of his relation, George Cooper.

While attending Guy's Hospital, Keats at first lived alone in what was then 8, Dean-street in the Borough, since built over by the coming of the railway. On Astley Cooper's advice he went, in January, 1816, to lodge with Henry Stephens and George Wilson Mackereth in St. Thomas's-street. At this time he was much occupied with poetry, but he qualified, as has been said, in July, 1816. He had still seven or eight months of a dressership to complete, but there is not a line to show that he ever went back to hospital, and he certainly never became a practitioner. During his medical studentship the orator said there were two Keats in one body. The one was (as shown by his notes, by the rapidity with which he qualified, and by the ease with which he passed his examination) a diligent medical student, sufficiently outstanding to attract the attention of the great Astley Cooper; the other was the poet. He would sit so often in the window-seat of his lodgings in St. Thomas's-street that it was called Keats's place. The story was that here, dreamily resting one evening while Stephens was studying medicine, the young poet broke out with the announcement that he had composed a new line. "A thing of beauty is a constant joy," he recited, asking, "What think you of that, Stephens?" "It has the true ring, but is wanting in some way," said Stephens, and went on reading. An interval of silence, and then Keats broke out with, "A thing of beauty is a joy for ever"—and thus was born in St. Thomas's-street one of the imperishable lines of English poetry.

JAUNDICE IN THE GERMAN NAVY.

In the March number of *Marine Rundschau*, a non-medical review dealing with naval interests, Marine Stabsarzt (Surgeon Lieut.-Commander) Dr. Heinrich Ruge gives an account of jaundice as a cause of invaliding in the German Navy. Between 1919 and 1923 he saw 1300 cases of jaundice, quite apart from cases of Weil's disease of which the exciting cause is definitely known. In these cases, commonly called "catarrhal"—although the term, according to Dr. Ruge, lacks pathological basis—the liver is usually enlarged, and may be tender. There is little risk to life, for only about one case in 900 is fatal, but great loss of service, inasmuch as cases are apt to be off duty for a month. Attacks often follow bouts of extra exertion, particularly when the places where work is done are badly ventilated, and for this reason, perhaps, bluejackets suffer less frequently than other men on board ship. An element of infection may be present, for of 19 officers who contracted jaundice 6 were medical officers, and the incidence on the sick-berth staff was also unduly high. The high prevalence of jaundice among the young recruits is ascribed by Dr. Ruge to impaired liver function dating from underfeeding during war-time. Dr. Ruge refers to the much-increased frequency of jaundice after salvarsan injections, which suggests to him that a liver, badly nourished as it was developing, is affected more seriously by both syphilis and salvarsan.

Manchester's Scheme to Aid Hospitals.—A new movement on behalf of the voluntary hospitals is being started in Manchester with the object of bringing the appeal for funds home to many people whose pockets are hardly touched at present, for the Hospital Saturday and Hospital Sunday collections do little more than touch the fringe of the population. Divisional committees corresponding to the Parliamentary divisions are now being formed, and these committees are to work in turn through newly formed ward committees. Each ward is to aim at raising £2000 by inducing people who do not make a regular contribution to the hospitals to make a weekly, monthly, or annual contribution. Every kind of society in the different divisions—social, political, or artistic—will be appealed to help the committees to reach these untapped sources of income. The annual deficit of the Manchester hospitals is £50,000, and there is a waiting list of over 2000 patients. It is sought to obtain £70,000 annually to cover the annual deficit and to allow for new expenditure on buildings.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CXXII.—THE TREATMENT OF TACHYCARDIA.

Tachycardia may be due to a variety of causes, and is a condition which for two reasons may demand treatment. In the first place, rapid heart action, quite apart from any associated structural lesion, seriously impairs the efficiency of the circulatory mechanism. A heart which beats rapidly when the body is at rest lacks reserve power. It is severely handicapped when called upon to increase its output in response to an increased demand of the muscles for oxygen during physical activity.

And, secondly, tachycardia may make itself distressingly manifest to the sufferer in the form of palpitation. When this is so, he is continually being reminded that there is something the matter with his heart; and this aggravates his condition by adding to the other disabilities from which he is suffering an element of constant mental anxiety. Even in the absence of palpitation, tachycardia, discovered perhaps by accident, will afford a fertile source of worry to the introspective patient. He keeps feeling his pulse, and each time he does so the gruesome features of the bogey of heart disease loom more clearly before his eyes.

Differential Diagnosis.

In health the rhythmic stimuli which excite the heart to contract arise in a group of specialised cells situated in the wall of the right auricle and known as the "normal pacemaker" or the "sino-auricular node." In accordance with the functional activity of this pacemaker, every case of tachycardia may be classified in one of two groups: either (1) *the primary tachycardias*, in which the disturbing factor lies within the heart itself—in these the stable government of the sino-auricular node has been temporarily or permanently replaced by a revolutionary régime; or (2) the *secondary tachycardias*, in which the rapid action of the heart is a mere secondary manifestation, indirectly or reflexly produced, by a lesion, or by the effects of a lesion, in some other organ of the body. Here the stable government is still in power, but has been obliged temporarily to modify its policy in response to urgent pressure from outside.

Secondary Tachycardias.—There are two simple and extremely important criteria in the diagnosis of secondary tachycardia: (1) the heart's rhythm is regular, and (2) the heart rate is highly susceptible to variation in response to changes of posture or emotional disturbances. If the pulse exhibits these two features, and if there be no rheumatic history or other evidence suggestive of an organic lesion, in my opinion, tachycardia, *by itself alone*, never justifies a diagnosis of heart disease.

Most of the cases of rapid heart action which we meet with in practice are secondary tachycardias, and it is extremely important to realise that, in them, the heart is not primarily at fault; the mere fact that in such cases we can assure the patient that his heart is perfectly sound will prove to be a psychotherapeutic factor of real value.

The treatment of cases in this group is essentially the treatment of the underlying condition, for with the elimination of the toxic or nervous factor which is bringing pressure to bear upon the heart the tachycardia automatically subsides. The simple tachycardia of Graves's disease, or of early pulmonary tuberculosis, that associated with various febrile conditions, or met with during convalescence from almost any acute illness, the tachycardia of neurasthenia, or that which occurs in perfectly healthy individuals as the result of some emotional disturbance, are all secondary tachycardias, and they are all generally easy to recognise.

In all types of secondary tachycardia, including "D.A.H.," any therapeutic measure which tends to direct the patient's attention to the heart is definitely harmful and should be most carefully avoided.

Primary Tachycardias.—In the treatment of the primary tachycardias, as in all forms of chronic heart disease, the restriction of physical exertion is of fundamental importance. The extent to which the patient is able and willing to adapt his mode of life to the limitations of his impaired cardiac reserve will largely determine the success or failure of any line of treatment. The diet should be such as will not cause flatulent distension of the stomach; the bowels should be carefully regulated, and excessive intake of fluid avoided.

As regards drug treatment, the practitioner has to decide whether he will strike at the root of the trouble and endeavour to restore the normal cardiac mechanism, or whether he would not do better to neglect the relatively unimportant auricle and concentrate upon the ventricle. He should ask himself three questions: (1) What chance is there of restoring the normal cardiac mechanism? (2) Is the normal mechanism, when restored, likely to be maintained? (3) To what extent is the patient likely to be benefited by the restoration of the normal mechanism?

Auricular Fibrillation.

The rapid heart action associated with auricular fibrillation is by far the most common of the "primary tachycardias." The features of this disorder, irregularity of the pulse both in rhythm and volume, numerous unproductive beats, which can be recognised by auscultation, but fail to reach the wrist, or even to open the aortic valves, and the commonly associated signs and symptoms of heart failure with venous congestion are characteristic and well recognised. In most cases the rapid ventricular rate is alone sufficient to account for the additional impairment in circulatory efficiency which accompanies the onset of fibrillation. It curtails diastole and thus hinders the filling of the ventricle, and it tires out the heart by frequent contractions, many of which are so premature that they serve no useful purpose. It is not surprising, therefore, that, without attempting to remedy the auricular mechanism, one can greatly improve the circulation by merely controlling the ventricular rate by means of digitalis.

The particular preparation selected is largely a matter of individual preference, but for general use either the tincture or the powdered leaf is eminently satisfactory. The larger dose of the infusion renders it less suitable when the drug is being given in large quantities, and the various proprietary preparations which I have tried appear to be less reliable in those cases of heart failure which demand immediate relief.

Recent work in pharmacology has shown that, in man, the absorption of digitalis from the alimentary canal is complete in six hours after administration, whereas the absorption of strophanthus from the alimentary canal is both poor and extremely variable. Full digitalisation can be rapidly obtained by the oral administration of massive doses. This procedure is perfectly safe provided the patient has not previously been taking digitalis or strophanthus, and provided that we allow an interval of six hours between successive doses. Morphine, gr. $\frac{1}{6}$, combined with the first dose of digitalis often brings great relief, by securing a few hours of much-needed sleep. The rate of elimination of digitalis from the body is such that, if necessary, a patient can take about 15 minims of the tincture per diem, over long periods of time, without any risk of cumulative effect.

The alternative plan of campaign is to attempt to restore the normal mechanism by means of quinidine, a procedure which requires careful supervision. In over 50 per cent. of cases of auricular fibrillation, normal rhythm can be restored temporarily by the use of quinidine, but it is only in a very much smaller number that the normal rhythm is permanent. When the symptoms are directly and mainly attributable to the presence of an abnormal rhythm, the results of quinidine therapy may be highly satisfactory; but when the myocardium is severely and permanently damaged control of the ventricular rate, by means of digitalis, is likely to yield greater benefit to the patient than the restoration of the normal rhythm, which is often too rapid for the damaged heart.

The procedure which I usually adopt, first having got the patient fully digitalised, is to give an initial dose of 3 gr. of quinidine, either as a powder or in the form of a cachet, and then, after waiting 12 hours to guard against the possibility of any idiosyncrasy to the drug, I give 6 gr. every three hours for five doses, and if necessary repeat this procedure on the two succeeding days. My own personal experience suggests that, if the normal mechanism is not restored before the end of the third day, although it often may be restored later by prolonging the treatment, it is not likely to be permanent. Quinidine tends to increase the ventricular rate, and digitalis may be given simultaneously to counteract this action. Quinidine is withheld if the heart rate becomes excessive, and is discontinued as soon as the rhythm becomes regular or toxic symptoms supervene.

Auricular Flutter.

In auricular flutter the pulse is generally regular, and in the neighbourhood of 150 per minute, while the auricle is beating at double that rate, every second auricular impulse failing to reach the ventricle. The degree of block between auricle and ventricle can be increased by digitalis, and the ventricular rate satisfactorily controlled in this way. By pushing the digitalis treatment, flutter can be converted into fibrillation; and then, if the drug be discontinued, in some cases the fibrillation will be replaced by normal rhythm. Flutter may persist for many years; but, provided the ventricular rate be efficiently controlled by digitalis, this disorder appears to impose surprisingly little additional burden on the heart.

Paroxysmal Tachycardia.

In true paroxysmal tachycardia the attacks commence and terminate absolutely abruptly, and for no apparent cause; the heart without warning suddenly switching over, in a single cycle, from the normal to an extraordinarily rapid rate of beating, often in the neighbourhood of 200 per minute. In any condition such as this, where the attacks are liable to occur at irregular intervals and to terminate spontaneously, it is exceedingly difficult, if not impossible, to assess the true value of the therapeutic agents which we have employed. Various methods of aborting the attacks have been advocated by different physicians, but none has proved infallible; and one is bound to admit that, at the present time, we know of no really reliable method of combating this disorder. Sometimes vagal stimulation, either direct, by pressure in the neck, or reflex, by the induction of vomiting or forced deep respiration, will abort an attack, but more frequently such methods fail, and we have to be content with endeavouring to prevent the attacks by carefully eliminating any infective, toxic, or nervous exciting factor.

Before becoming permanently established, auricular fibrillation is liable to occur in paroxysms which alternate with periods of normal rhythm. Although it may hardly seem justifiable to draw any conclusions as to the results of treatment in such paroxysmal attacks, quinidine does appear to yield good results.

Structural cardiac lesions are generally permanent, but derangements of function are often extremely amenable to treatment; by appropriate management and drug therapy we can do much to restore balance, to relieve symptoms, and to enable the heart, even when badly damaged, to carry on its functions in a fairly satisfactory way for long periods of time.

J. Crighton Bramwell, M.D. Manch.,
M.R.C.P. Lond.,
Registrar in Charge of the Cardiographic Department, Manchester Royal Infirmary.

Special Articles.

PROCEEDINGS OF THE ROYAL COMMISSION ON NATIONAL HEALTH INSURANCE.*

(Continued from p. 995.)

Evidence of the British Dental Association.

(App. XIX.) The British Dental Association submitted evidence on the dental treatment at present available, the need for the extension of dental treatment and for its establishment as a permanent statutory benefit, and the scope of such a permanent service.

The evidence was given by Mr. J. H. Badcock, President-elect, Mr. E. Y. Richardson, and Mr. B. J. Wood.

Early Recognition of the Need for a Public Dental Service.

Organised schemes of dental aid for persons who could not afford private dental fees were not unknown prior to the Insurance Act. Following upon the passing of the Act of 1911, and independently of State support or recognition, a scheme for a Public Dental Service to be available for all persons coming under the age-limit of the National Health Insurance Act was drawn up and preparations were made for making dental treatment available under it in all parts of the country. The outbreak of the war prevented the realisation of this project, but it was revived after the 1918 valuations of Approved Societies, which set free surplus funds available for additional benefits, amongst which was included dental benefit.

Panels of Dentists.

The British Dental Association took the initiative in calling meetings throughout the country which every registered dentist was invited to attend, with the object of organising panels of dentists who would undertake to treat insured persons.

(App. XIX., 4–7. Q. 9212.) Up to the passing of the Act of 1921 the British Dental Association represented from three-fifths to two-thirds of the practising members of the profession. It has not so far admitted to its membership the "1921" dentists. When the panels were formed they soon felt the need for coöperation and for uniformity of action and control, and in December, 1922, combined to form themselves into the Public Dental Service Association of Great Britain, Limited. This Association numbers nearly 7000 members.

Criticisms of the Present System.

(App. XIX., 10–14. Q. 9228–9.) The present system was criticised by the witnesses on account of the unequal distribution of the benefits, the different proportions of payment met by the societies, and the fact that each dentist has to deal with a great number of different societies.

---

* In previous articles the proceedings of the Commission were reported under the following headings: Introductory Note; The Scope of the Insurance Scheme (see The Lancet, Jan. 31st, pp. 247–8); The Provision of Medical Benefit (Feb. 7th, pp. 301–3; Feb. 14th, pp. 355–6; Feb. 21st, pp. 403–5); Financial Provisions of the Act (Feb. 28th, pp. 454–7); Medical Certification and the Regional Medical Staff (March 7th, pp. 508–9); The Approved Societies and the Money Benefits (March 14th, pp. 564–5; March 21st, pp. 623–4); Evidence of the Hearts of Oak Society (March 28th, pp. 677–9); Evidence of the National Conference of Industrial Assurance Approved Societies and of the Manchester Unity Approved Society (April 4th, pp. 731–3); Evidence of Independent Order of Rechabites, of Rational Association Friendly Society, and of Miners' Societies (April 11th, pp. 784–6; April 18th, p. 839); Evidence of Mr. Alban Gordon (April 18th, pp. 839–40); Evidence of Joint Committee of Approved Societies, of Stock Exchange and Lloyds' Health Insurance Societies, and of Group of Catholic Approved Societies (April 25th, pp. 889–91); Evidence of the National Insurance Beneficent Society (May 2nd, pp. 943–4); Evidence of the British Medical Association (May 9th, pp. 993–5).

References to the paragraphs in the printed statements issued as appendices to the reports of the oral evidence are given thus: "App. X. 69," and references to the oral evidence thus—Q. 1369.

> If the individual dentist had to deal with one body, say the local insurance committee, for the whole number of his cases instead of having to deal with 300 or 400 societies as at present, all slightly differing, it would enormously lighten his burden of correspondence and would lead to greater efficiency in many other ways.

It was also suggested by the witnesses that although in some cases emergency treatment is definitely provided for in the arrangements, some societies, when a claim has been made, have repudiated it on the ground that a " dental letter " had not been completed. Even among members of the same society there is inequality of treatment owing to the fact that where the patient is unable himself to find a portion of the dentist's fee he has usually to decide to go without the treatment.

The statement sometimes made that about 7 millions of insured persons are entitled to dental treatment creates quite an erroneous impression. As already stated, so many members have to give up their claim to benefit because they are unable to pay. Further—

> Adolescents joining societies which give dental treatment as additional benefit are not eligible for such treatment when they join, but must wait a variable number of years before they become entitled to the benefit, thus losing the advantage of dental treatment at the very age when it is most needed and would do the greatest amount of good.

Perhaps the best that can be said about the present service is that—

> It has afforded opportunity for the experimental testing of a means of supplying dental treatment and has demonstrated that the members of Approved Societies are eager to take advantage of such facilities for dental treatment as have so far been provided.

The Need for an Extensive Scheme.

(App. XIX., 24–35.) Reports of Departmental Committees and of various authorities are quoted in an appendix to this evidence, and it is suggested that they prove up to the hilt the case for a wide extension of public dental service. Any campaign against national disease which neglects this, one of the chief outposts of preventive medicine, is making a tragic error. Also, the evidence states—

> Employers of labour who have established dental clinics for their workpeople are unanimous in testifying that, philanthropy apart, the treatment pays in increased efficiency of the worker and diminished loss of working hours through indisposition.

A Complete Service.

(App. XIX., 32–8.) The remedy for the present unsatisfactory provision is not an extension of additional benefit, but a complete scheme which would include :—

> (1) Dental treatment at maternity and child welfare centres ; (2) treatment during school age ; (3) treatment for adults and their dependants under an insurance scheme.

Such a scheme should embrace :—

> The extraction of teeth under local or general anæsthetics. The scaling of teeth and the treatment of inflammatory conditions of the mouth. The filling of cavities in carious teeth. The provision and repair of partial and complete artificial dentures.

(App. XIX., 42.) The most urgent necessity is a complete school dental service staffed and organised so that every school child during its entire school age has dental treatment of a preventive and curative nature. This service should be linked to, and should follow on, an equally complete scheme of dental treatment for children under school age and for expectant and nursing mothers.

> Until these services are effectively organised, adult dental treatment of the industrial classes must remain chiefly a matter of extraction of septic teeth and the insertion of dentures, which is a perversion of the highest requirements of public health and an outrage on common sense.

Medical Benefit Machinery Recommended.

(Q. 9220–30.) The witnesses suggested that the service for a statutory dental benefit should be controlled as regards the local arrangements by the Insurance Committee in the same way that medical benefit is at present administered ; that there should be a dental panel committee, a dental service sub-committee (for dealing with complaints), and regional dental officers.

The Cost of the Service.

(Q. 9245–6.) Careful analysis of various figures have resulted in the Association putting forward the suggestion that 5*s.* per head of the insured population is the best approximation that can be made at the present time of the cost of a complete service. The witnesses said, however, that the actual payment of the dentists by means of a capitation fee was not practicable. (Q. 9320.) Abuses under a system of payment for services might be checked by the proposed regional officers.

(Q. 9456–61.) On a 5*s.* basis it was pointed out to the witnesses that this would put roughly £500 a year into the pockets of every one of the 7500 dentists taking part in the scheme. The reply was that this would by no means represent all new income to the dentists, and that, in any case, the numbers would be nearer 10,000 than 7500.

An Adequate Supply of Dentists—and the Demand.

(Q. 9125–8, 9385.) The witnesses said that an adequate number of registered dentists would be forthcoming to run a satisfactory service for the whole insured population. A complete scheme could almost certainly not come into full being all at once, and as it grew the dental profession could be relied upon to meet the increasing demands.

(Q. 9230.) The average demand-rate was thought to be about 5 per cent., which gives 750,000 cases a year for an insured population of 15 millions.

Clinic v. *Panel.*

(App. XIX., 19–23.) The panel system was advocated as being readily adaptable to meet small or large demands and as facilitating free choice of dentist. The clinic system permits of the effective handling of large numbers where a continuous supply of patients is assured.

(Q. 9241–2, 9254, 9406–12.) The dental profession, in any case, would object to clinics with whole-time salaried officers controlled by Approved Societies ; they would not object to clinics organised by the dentists themselves or of arrangements made under which part-time dentists were paid a fee per session. Such clinics would permit of specialised treatment—X rays, violet rays, and ionisation—not always available in a private surgery. It appeared that in objecting to lay control the witnesses were visualising the possibility of interference with the professional treatment of a patient. They said they would not mind in the least control which was confined to administration and questions of discipline, provided that there was some dental representation on the governing body.

EVIDENCE OF OTHER DENTAL ORGANISATIONS.

British Society of Dental Surgeons.

(App. XX. Q. 9462–9626.) The evidence for this society was given by Sir Frank Colyer and Dr. E. W. Fish. They emphasised the importance of a national scheme for the prevention of dental disease and urged that prophylactic measures should have the first consideration. It was of great importance that the dependants of the insured should be included as soon as funds were available. In the meantime they made recommendations for an immediate scheme of treatment for the insured estimated to cost 3*s.* 6*d.* per head, and limited at present to (*a*) propaganda, (*b*) extraction of tender or hopelessly infected teeth under suitable anæsthetics ; and (*c*) scaling of the remainder. As regards administration, the formation of panels of dentists was suggested and generally the same machinery as for medical benefit. For the administration of general anæsthetics an addition to the medical capitation fee would be necessary.

A Clean Mouth More Important than Dentures.

The witnesses suggested (Q. 9498) that any insurance scheme should be limited to extractions and fillings, and that if patients wanted dentures they should provide them out of their own pockets. The provision of dentures was, it was suggested, not at all an essential to health, but was largely for matters of appearance. The "1921" dentists were far too prone to extract teeth and put in dentures, and generally the witnesses thought that there was room for propaganda amongst the dentists themselves as to the importance of preventive treatment and the preservation of the clean mouth rather than remedial treatment.

Public Dental Service Organisation.

(App. XXII. Q. 9787–10,060.) This evidence was given by Mr. J. Clifford Wing, the Chairman, and Colonel Howkins, Mr. A. H. Condry, and Mr. P. I. Wigoder. This association came into existence as a direct result of the demand for dental benefit out of the surplus funds of Approved Societies. It contains 7000 members and embraces the great majority of Insurance dental practitioners. The witnesses were whole-heartedly in favour of a large extension of dental treatment under the Health Insurance scheme and said that their cordial coöperation would be forthcoming. The cost of the provision of public dental treatment would, they suggested, be largely off-set by a reduction in the quantity of medical treatment needed.

They endorsed the earlier evidence as to the lack of uniformity in the present system of administration by various Approved Societies, as to the objections to clinics, and agreed that there would be an adequate supply of dentists forthcoming for a national scheme.

Linking-up Provisions.—They urged that any scheme of dental benefit would be defective which was not linked up with the existing provisions for the treatment of dental disease among children and which left any gap in the supervision and treatment of dental disease between childhood and maturity.

Scope and Cost of a National Service.—The witnesses suggested that professional opinion would be found almost unanimous in approval of the following schedule: Carefully organised propaganda as to the care of teeth, with a view to the prevention of dental caries and other disease; scaling of teeth and treatment of inflammatory conditions of gums; fillings; extraction of teeth under (1) local, (2) general anæsthetics; provision of (1) complete, and (2) partial artificial dentures. The cost on such figures as were available would be met by 1*d.* a week per insured person, but it was thought that this might be found to be an under-estimate. The witnesses indicated the order of precedence for these services (Q. 9829): (1) Extraction of teeth, (2) scaling and filling, and (3) the provision of dentures. Propaganda should, they thought, be carried out by the Dental Board. They disagreed entirely (Q. 9882) with the suggestion which had been made that it was not necessary for the health of an adult that he should have his bad teeth replaced by dentures.

Cost and the Safeguarding of the Funds.—The witnesses handed in the scale of charges agreed with the Approved Societies, which is a lengthy document and includes amongst other items: extractions with local anæsthetic 2*s.* 6*d.* a tooth up to three, and a maximum fee for upper and lower jaws of £1. For a full denture, upper and lower plates, including any necessary extractions, £6 10*s.* is paid. The capitation fee of 1*d.* per week per insured person suggested above was based, it appeared, upon the cost to an Approved Society under a scheme where the members themselves had to pay a part. The risk of an indefinite charge under a national scheme where the dentist was paid for each service rendered might be safeguarded: (1) by the fact that dentists were honourable men; (2) by the unpopularity of dental treatment; and (3) by the appointment of regional dental officers. Medical certificates were quite unnecessary (Q. 9949). "Medical men do not understand anything about dental conditions." Subject to the supervision by the Regional Dental Staff, the witnesses thought that the bills for treatment would have to be met in full, and that if there was not enough money to meet them the State ought to find the balance.

The Incorporated Dental Society.

(App. XXVIII. Q. 11202–11392.) This society, for whom evidence was given by Mr. W. F. Bower and Mr. Butterfield, contains about one-third of the 7000 "1921" dentists. The objections already urged by other witnesses to the present partial scheme and the varying standards of administration were reiterated. A great deal of the evidence was taken up with the objection felt to clinics as being "contrary to the psychology of the average insured person" and also bad professionally. The witnesses suggested inter alia that the dental benefit must be adequate and free of cost to the patient, and that there must be free choice of dentist. There was a sufficient number of dentists to give complete treatment and to overtake arrears.

The suggested cost was 1½*d.* per week per head of the insured population, and the dentists undertaking service would certainly object to any scaling-down of their bills.

ROYAL COMMISSION ON LUNACY AND MENTAL DISORDER.

FURTHER SITTINGS.

(*Continued from p. 889.*)

THE Commission held a further session on May 4th and 5th, Mr. H. P. Macmillan, K.C., the Chairman of the Commission, presiding.

EVIDENCE OF THE MEDICO-PSYCHOLOGICAL ASSOCIATION.

The two days were occupied by the evidence tendered by the Medico-Psychological Association of Great Britain and Ireland. That body was represented by Dr. R. H. Cole (chairman of the committee appointed in July, 1924, to prepare a précis of evidence), Sir Frederick Mott, F.R.S., Lieut.-Colonel E. Goodall, Lieut.-Colonel J. R. Lord, Dr. W. F. Menzies, Dr. R. Worth, and Dr. M. Abdy Collins.

The evidence set out that the Association was established in 1841, and its objects were to facilitate intercommunication on all matters concerning the care, treatment, and recovery of patients suffering from mental disorder, and the collaboration of research into and the elucidation of the causes of insanity and its prevention. It was now some 800 strong, and a large proportion of the members were medical superintendents or medical officers of mental institutions. Since 1892, 379 medical men had been awarded its certificate in psychological medicine, while 18,000 certificates in mental nursing had been granted by it.

In regard to the general aspect of the subject the committee state that the need for legislative action before certain progressive lines could be followed had militated against the real advance which those engaged in this work desired.

In 1911 a committee was appointed by the Association to inquire into the status of British psychiatry, and it reported grave defects under which the specialty in this country laboured. Two of the chief of these were (1) the absence of proper provision for the early treatment of incipient and undeveloped cases of mental disorder; (2) the paucity of facilities for the study of psychiatry and for research. This committee recommended the establishment of clinics for mental disorders in connexion with universities, medical schools, and general hospitals; also that, as a general principle, the admission to all mental institutions should be on a voluntary basis, and loss of civil rights should not be consequential thereto. A further recommendation was that incipient cases should be detainable for a limited period, such cases being notified to the Board of Control; and that admissions to mental institutions should have no relation to poor-law authorities. They also asked that the use of urgency or provisional orders should be widened.

It was the view of the Association that the vast majority of the community, patients included, was grateful for the protection given by the present Lunacy Acts, and that on the whole the safeguards they provided against abuses and illegal detention had proved satisfactory. These Acts had failed, however, to keep pace with medical progress, especially in regard to the treatment of initial and more curable stages.

The Association state that many medical practitioners, not having had means of learning the manifestations and treatment of early mental disorders, failed to recognise the seriousness of them and the need for efficient treatment. Many such patients belonging to the well-to-do classes, who were certifiable, were now in private houses and nursing homes without any order having been obtained for their reception, and no intimation of such admission had been given to the Board of Control. There should be opportunities for the competent authority to ascertain that these places were suitable for the purpose.

The evidence tendered by the Association included appendices by Sir Frederick Mott (on better provision for early treatment), by Lieut.-Colonel Goodall (on a cognate subject), and by Lieut.-Colonel Lord (on psychiatry in some European countries and in America).

The Association's Recommendations.

The recommendations of the Association number no less than 57. The following are some of the points:—

In the organisation of clinics, special provision should be made for children, and the clinics should be, where possible, annexed to a general hospital or housed in a special building. Their medical and nursing staffs should include those specially trained in psychiatric work. Local authorities should provide and maintain these clinics or avail themselves of voluntary organisations for the purpose. Inspection and approval of the buildings so used should devolve upon a central Government department. In the case of voluntary patients, a 72-hour notice in writing should be required if a patient wished to leave the institution. The central Government department should have power to approve homes which were supported, wholly or in part, by voluntary contributions, or which were privately owned, which could lawfully receive without certification more than one paying patient who was suffering from early mental disease. All matters of mental health should be centralised in the Board of Control, which the Association preferred should be known as the Board of Mental Health, and that it should have a larger staff. When appointments were made as Medical Commissioners of the Board of Mental Health, consideration should be paid not only to the candidate's experience in mental disorders, but also to status and experience in the medical profession as a whole. The management of all rate-supported institutions for the care and treatment of mental disorders should be vested in one statutory committee of mental health of a local authority; the county or borough rate should be utilised to support the maintenance of necessitous patients, as well as of the fabric of public mental institutions, the rate being supplemented by a Government grant. A further recommendation was that the words "lunacy" and "lunatics" should be replaced by "mental disorders" and "persons of unsound mind"; and "asylum" by "mental hospital"; also that two medical certificates should be required for rate-aided as well as for private patients. The committee considered that there was need of simplification of forms under the existing Lunacy Acts, and that leave of absence on trial or for health should be encouraged. They further thought that the automatic discharge of a patient by escape after 14 days was undesirable. The after-care of rate-aided patients should be considered, and the work of such bodies as the Mental After-Care Association should receive adequate pecuniary recognition by statutory committees. Patients alleged to be of unsound mind should not be removed to a workhouse infirmary before their reception at a mental hospital. Patients transferred from a mental hospital to a poor-law institution should be transferable back again without re-certification. Reports on mental cases in all Poor-law institutions should be notified to the Board of Mental Health, and better provision should be made for the care and treatment of senile cases in infirmaries approved by the Board of Mental Health. The committee's final recommendation was that the protection afforded to medical practitioners by Section 330 of the Lunacy Act, 1890, should be extended so as to stay proceedings at an earlier stage than at present, and that they should receive the same immunity as that granted to witnesses in a court of law.

Colonel Goodall, in his special appendix, says that the Lunacy Acts of England and Wales mainly concerned themselves with the segregation and care of the "lunatic," the protection of him and his property, and of the public, and a perusal of the Acts left the impression that merely an alien was being dealt with, not a sick man. He also says that, apart from the Maudsley Hospital, we in England and Wales had long been merely marking time in psychiatry.

The Chairman put a number of questions as to the work done by the Association in improving mental nursing, and the provisions of the new General Nursing Council. Dr. Collins said the Association proposed to continue to hold its examinations for nurses. Dr. Cole said it was felt by the members that an unnecessary amount of records were required to be kept. This was such a burden that it really interfered with the treatment of mental disorder. As to the safeguards of the present statutes, these, except in certain minor respects, could not be improved upon.

Voluntary Treatment.

With regard to treatment of the early stages of the disorder, Colonel Goodall said the Association had pressed for some time for a relaxation of the law in this direction. The mental clinic should be under the same administration as the general hospital. He did not think it was wise to have mental patients in general wards. He thought all kinds of early cases should be admissible to the clinic; here the treatment would be more intensive than in an ordinary asylum: there would be a larger proportion of staff, and the latter would be assisted by other medical men. He disliked the idea that these clinics would be corridors to the asylums.

The question of voluntary patients was discussed in a conversational way round the table, views being freely exchanged. Dr. Menzies drew attention to the class of case already certified and in a mental hospital who became physically ill and needed surgical or other special treatment, such as a general hospital was continually giving. These could be transferred to the general hospital clinic for a period.

Stigma.

Dr. Menzies expressed the view that the stigma which was generally held to attach to mental disease would be greatly diminished with the spread of education and enlightenment. A large part of the objection to being certified was found to consist in the fact that patients who had been discharged from a mental hospital were proved by experience to be unemployable, however well they might be deemed to have recovered. The statement was often made: "He may have a relapse at any time: he might have one now."

Sir Ernest Hiley suggested that if a man mentally ill were removed by the sanitary inspector he would probably be stigmatised, and Dr. Collins asked why the same person should not do this as acted in the cases of scarlet fever. Dr. Cole said many voluntary patients themselves told their friends that the place they had been to was really an asylum. Still, a man who went to an ordinary hospital would be regarded as less mentally ill than if he were to go to the Maudsley Hospital. Sir Ernest Hiley said that even a special ward for these cases in a general hospital was known as "The Balmy Ward," and Colonel Goodall retorted that that was no reason why people should be denied the benefits attaching to such a ward.

Classification.

Sir Frederick Mott said it was desirable to have, in association with mental hospitals, what was known as an "acute block" outside the mental hospital grounds so that patients here would not mix with chronic lunatics at all. Many mental hospitals were without this provision. These would be for the more curable cases and would be useful as clinics to which general practitioners could bring their patients. Dr. Cole said that, wherever possible, mental clinics should be in association with general hospitals. In answer to the Chairman, he said that rate-aided and the private patient should be assimilated in the matter of legal procedure. There should be no distinction simply because one had money. The two medical certificates recommended for each class of patient could be given after consultation, but there should be a separate examination of the patient by each of the medical signatories. Colonel Lord said it had been felt all along that the Poor-law officials were not the right people to have charge of the insane. The Association considered that the county council or the borough council should not only build and maintain mental hospitals, but that they should take over all the duties and responsibilities in connexion with those patients. That would be better for the patients, better for the administration, and would probably be, in the long run, more economical.

The Patient's Rights.

Dr. Menzies, in answer to a question by the Chairman, said that the justices acting in this work should be specially chosen—perhaps by their brother magistrates—by reason of their experience and interest in lunacy work. With regard to the right of a patient to see a magistrate, Dr. Cole said the exercise of this right was sometimes very upsetting to patients, especially as the form to be filled up was such an elaborate one. Dr. Menzies said the fundamental principle of all the Association's recommendations was to render the treatment of the patient as a sick man as easy as possible, and to make improper detention as difficult as possible.

Lord Russell asked in how many cases a second certificate would prevent a man being wrongfully detained, and Dr. Menzies replied that in ten years' time it was hoped that the permanent certificates would be reduced to a fourth of the present number.

Sir David Drummond asked whether the Association's view was that the second certificate should be given by an expert in these diseases, and Dr. Cole replied that it was felt that the right of supplying the second certificate should not be taken from medical men as a whole; but they felt that every medical man should have some proficiency in mental diseases.

The Central Authority.

Dr. Menzies was questioned upon a supplementary memorandum which he had supplied, chiefly on the question of the central authority. He said his view was that the paid Commissioners should consist of five medical men and two legal members. The medical members should be paid at least £2000 per annum, and years served under a local authority should be taken into account in determining the pension. At present questions were kept held up at the Board of Control two or three weeks. He also suggested that there should be district inspectors. The feeling of the Association was that the gentlemen so appointed should be high experts, men of the highest medical and scientific attainment. He mentioned the late Sir Clifford Allbutt as the type of man the Association had in mind.

Licensed Houses.

Dr. Cole said it was felt that when the Act of 1890 came into force, the stoppage of the extension of licensed houses due to it was a mistake. The general public wanted their relatives who were mentally ill to go to a place they themselves selected. A considerable proportion of people and doctors preferred the licensed house. When those houses were full there was a tendency to evade the Lunacy Act, to keep in houses patients who ought to be certified to the Board of Control but were not. The present distribution of licensed houses was very unequal. By interfering with private asylums one was interfering with private single patients and with private practice, considered as a whole.

Asked as to possible collusion in these houses, Dr. Cole said the only collusion he could think of was between a medical officer and a relative of a patient. He felt sure there was no risk of exploitation of patients.

Lord Russell suggested there might be a temptation to extend the time of detention of a patient beyond the needed period, but Dr. Cole said he did not think that was so; people did not pay more for the care of their relatives in these circumstances than they could help. Some preferred to remain on as voluntary boarders, and there seemed no good reason why they should not. Lord Russell explained that the real point was the suspicion of the public that on occasion interest might conflict with duty.

Female Nurses in Male Wards.

Colonel Goodall was questioned about his experiences in having male wards nursed by women. He said his individual view was favourable to this—the Association as a whole had not pronounced on the matter. Six of his wards were under female nurses, and in two of them there were no men at all. That had been the case in his mental hospital since 1920. In three war years he had great experience in the treatment of mental cases, some of them very severe, and these were under the care of trained female mental nurses, some men being, during the war, employed in a subordinate capacity. Women, he found, were able to exercise sufficient control over these male patients, except in the small matter of exercising in the gardens. From the therapeutic standpoint he was sure women were far superior to men for the work; there was a psychological and sex basis for this. This employment of women nurses in male wards had been attacked by the local trades-unions, on the moral ground, and that of the alleged unnecessary supplanting of the men. Both these objections were false, and he had not discharged a man so that a woman could be appointed.

Psychiatric Education and Research.

At the short sitting on Tuesday the chair was occupied during part of the time by Mr. Micklem, K.C.

Sir Frederick Mott spoke of the need for better provision for education and research in connexion with mental disorder. In 1907 he felt convinced that the diploma in psychological medicine would be of equal value to the D.P.H. Now, in L.C.C. mental hospitals the possession of this diploma was a sine qua non for a senior appointment. It was granted only to men who had been a year or two in asylums. There were at present only three holders of the London University doctorate in psychological medicine. He outlined a plan whereby, for purposes of research, several asylums would have a central laboratory, apart from the laboratory of each. Colonel Goodall said that at Cardiff large sums of money had already been spent on research. The present teaching on psychiatry was inadequate in this country, far worse than at Utrecht University, for instance. Sir Frederick Mott argued in favour of team-work which had brought about advances which no individual work could have done.

MEDICINE AND THE LAW.

SALE OF MILK "AS IT CAME FROM THE COW."

AN appeal was heard recently in the Divisional Court in which J. Bridges, an inspector under the Sale of Food and Drugs Act, appealed against a decision of the justices at Stow-on-the-Wold dismissing a summons that he had taken out against J. Griffin, a dairyman. The appellant had bought from a roundsman employed by the respondent a pint of milk, which on analysis had been found to be deficient to the extent of 46 per cent. in milk-fat. The milk had been drawn from a tap at the bottom of a churn. The respondent had given evidence of having instructed his man to stir the milk before drawing it off for a customer; but whether this had been done or not the magistrates had been satisfied that the milk was put into the churn in the state in which it came from the cow, and that no one had had access to the churn or had tampered with its contents. The question argued, therefore, was in substance whether an "abstraction" of cream, within the meaning of the Milk Regulations, 1901, takes place if milk has been drawn from the bottom of a churn, when some of the cream which should go to the customer has risen to the top. The summons was for selling milk not of the nature, substance, and quality demanded by the purchaser, not for actually abstracting the cream, the Milk Regulations, as was argued on behalf of the respondent, establishing no standard for what should constitute milk, but providing only that if it has failed to reach a certain standard adulteration by addition of water or abstraction of fat should be presumed. It was contended that where the analyst's certificate only was relied upon by the prosecution, proof that the milk was put in the churn as it left the cow and had not been tampered with was a good defence.

The Lord Chief Justice gave judgment allowing the appeal, in which Mr. Justice Avory and Mr. Justice Shearman concurred. Lord Hewart said that the case had resolved itself into a question whether there could be said to be abstraction of milk-fat where all that had happened was that the milk had been poured in bulk into a receptacle and, after the cream had risen, had been sold as new milk, when owing to the construction of the receptacle it had been drawn from the bottom. The regulations did not supply a definition of milk, but supplied a means of proof. The milk, however, to which the regulation referred was not the milk in bulk in the churn, but the actual sample sold to the customer. In *Hunt* v. *Richardson* [(1916) 2 K.B. 446] it had been found expressly that nothing had been subtracted or added, and the defence that the milk was "as it came from the cow" had been adopted ever since. The important moment was, however, the moment of sale, and the important milk was the milk that was sold. It was not enough to say that there was a time when it formed part of milk which was in its natural state. The milk as put in the churn was found by the magistrates to have been in its natural state. There was no finding that the sample sold was in that condition, and it was contended that the cream had risen to the top owing to the churn having been allowed to stand. In *Dyke* v. *Gower* [(1892) 1 Q. B. 220] cream had been abstracted from milk at the bottom of a receptacle because milk had been taken up from the top by means of a dipper; this was the reverse of what had happened in the case under discussion. His Lordship asked whether if a seller put milk into a receptacle knowing that the cream would rise to the top, and then sold from the bottom, he could say that milk so denuded of cream was as it came from the cow. In *Dyke* v. *Gower* the abstraction of cream had been ascribed to "neglect to keep the milk stirred." His Lordship referred to Scottish cases which appeared to harmonise with the reasoning in *Dyke* v. *Gower*. There was nothing in the case before the Court on which the magistrates could find that the milk was in the condition in which it came from the cow, and the right conclusion was that it was not of the nature, substance, and quality of that which was asked for. There was also evidence that the defendant knew what would happen if the milk was not stirred, but no evidence to show that to stir it would be impracticable. The appeal, therefore, ought to be allowed.

The successful appellant in this case is to be congratulated, as does the local authority for which he acted, upon having secured a decision which will be of great value to others having like responsibility for maintaining the quality of milk sold throughout the country. The importance of Lord Hewart's judgment lies in the attention which it calls to the essential question of the condition of the milk actually sold, and to its condition at the time of sale. This, of course, is what really concerns the customer and consumer. A housewife who buys milk deficient in cream can derive no consolation from the possible fact that it once formed part of a larger quantity of milk which was rich in cream, or from the fact that no deliberate or mechanical abstraction of cream from it has taken place. It is also clear that the decision inflicts no hardship on the great majority of honest milk-dealers, who only wish to supply good milk, and who know that they can put it in bottles and sell it in them as it came from the cow, or can see that their men keep it stirred with a plunger when on their rounds. The plunger, however, should be so fitted that it can be used without exposing the milk to any external contamination. Of this also milk-dealers are well aware.

BAKER'S ITCH AND WORKMEN'S COMPENSATION.

In a paper read before the Royal Society of Medicine, Section of Dermatology, in October, 1924,[1] on the subject of "baker's eczema," Dr. Prosser White and those who joined in the subsequent discussion showed that there is by no means unanimous medical opinion as to the causes of the symptoms complained of by workmen who seek compensation for this affection. Dr. White indeed suggested serious doubt as to whether the claimants of such compensation had a primary morbid condition of the skin, and whether there was in fact any rash peculiar to those who prepare bread and confectionery for human consumption. In an interesting compensation case heard recently at Hanley, and briefly reported in our last issue, his honour Judge Ruegg had before him a workman fully recovered, who had suffered from the complaint and anticipated its recurrence if he returned to his work. The judge held that to compensate a man for that from which he was not suffering would be to compensate him for life, and that if the man returned to baking and developed the disease again he could claim compensation as for a fresh accident. It was intimated, however, that there would be an appeal, which will be awaited with interest by bakers and confectioners. In view of the opinions expressed at the meeting of the Royal Society of Medicine it would be interesting from a medical point of view to know whether on such occasions as the above the evidence proves that the workman's illness is directly and exclusively due to his occupation. If there is a predisposition to eczema it would hardly seem fair that a man should be compensated permanently, merely because he has developed it through engaging in work likely to have that effect, and another form of livelihood would seem to be indicated. If, on the other hand, the making of bread and confectionery tends to cause eczema in previously healthy workmen in England, the desirability of devising and enforcing suitable precautions is immediately suggested. Dr. White said that baker's eczema is unknown in France, and that American statistics point to a similar immunity being enjoyed by workers in the United States.

Public Health Services.

SCHOOL MEDICAL SERVICE.

YEAR by year increasing space is being given in the general press of the country to reports by school medical officers, some of whom give very full accounts of the work being done and the remedial measures adopted. There is evidence in the reports for 1924, now before us, of a practical desire to interest the layman as much as the statistician.

Name of district.	No. on roll.	Av. elem. school attendance.	No. examined in "code" groups.	Special examinations or inspections.	Percentage of children found on routine examination requiring treatment.†
Ilford ..	10,693	—*	4,007	10,719	40·2
Gillingham	7,540	6,880	2,761	1,690	14·0
Eccles ..	—*	—*	2,315	5,733	22·7

—* = Not given.
† Excluding cleanliness and dental defects.

Ilford.

Dr. A. H. G. Burton, in his report to the urban district council, points out the steady decline of cases of scabies from 146 in 1920 to 5 cases in 1924, and of impetigo from 586 to 256 in the same period, and the small figure of 5·6 per cent. of verminous heads reflects favourably on the interest his public are taking in hygiene generally. The steady rise in the percentage of parents attending the medical examinations to 71 per cent. is encouraging. 13·8 per cent. of the children examined were found to be suffering from unhealthy conditions of the nose and throat, and as 302 children who had either suffered and are suffering from discharging ears or defective hearing are known in the district Dr. Burton suggests that an aural surgeon ought to be appointed. Of 62 per cent. of children requiring dental treatment 62 per cent. accepted it; 13·5 per cent. children required treatment for visual defects, and all who were recommended glasses obtained them.

There was a distinct drop in all the infectious diseases except measles during the year. Dr. Burton hopes that an open-air school may be opened this year to accommodate the 177 pre-tuberculous children in the district. In Ilford no school meals are provided and no special schools exist for physically or mentally defective children. The point is raised of the two definitions of feeble-minded, and Dr. Burton contends that the "social" definition now applied to those over 16 years should be made to apply to all ages, and some other class of certificate provided for children who require special education. This would cause no stigma to the child, and such children could be educated with dull and backward children, and if suitable be transferred later to an elementary school. Such a course would entail institutional care for children certified under the Mental Deficiency Act at prohibitive cost, to say nothing of the parents' objection to having their children removed. As it is now most certifying officers hesitate to certify any child who might ultimately be returned to an elementary school, and statistics show how few of the children once certified ever do return. Dr. Burton, in explaining the paucity of certified children in his area, states that he has avoided notifying as mental defective children who are merely mentally retarded.

In the return of goitre cases 13·8 per cent. had slight enlargement, 2·4 per cent. marked enlargement, and 0·6 per cent. such enlargement as to suggest that treatment may be required. The school nurses carried out 35,450 examinations during the year. From the table of average heights and weights of Ilford boys and girls, which is shown in comparison with the anthropometric standard, it appears that 8–9 year old Ilford boys are 2·78 inches taller and 1·37 lb. lighter than those in the standard.

Gillingham.

From the above statistical table it will be seen that the standard of defect for which treatment is recommended is distinctly low in Gillingham. Dr. W. A. Muir, in his report to the Education Committee of the borough, points out the complete coördination now existing between the various health services, so that the records of ailing children are available from all sources. The hygiene of the non-provided schools in his area is generally below requirements. At routine examinations 7 per cent. of the children were verminous, and at the nurses' surprise visits 13·4 per cent. of the average attendance were verminous. A table showing the percentage of unclean children in each school by introducing a competitive standard should have useful results in the future. The decrease in the incidence of ringworm and impetigo is commented on, but no comparable figures are given for past years. Defects of the nose and throat were found in only 6·3 per cent. of "routine" children, and of those requiring treatment for tonsils and adenoids 55·6 per cent. obtained it, the cost to the authority being £1 4*s.* 6*d.* for the operation. Treatment for defective hearing and disease of the middle-ear was required in 0·94 per cent. of Code group children.

As the dental clinic is open on only three half-days per week only the worst cases of dental caries could be referred for treatment—i.e., 19·6 per cent. of the intermediate and "leaver" groups and 21·6 per cent. of the 5 to 8 year-olds. This condition of affairs is scarcely one on which the local education authority can congratulate itself. The local dentist is an optimist. He writes: ". . . . I am sure I can get 2*s.* for gas extractions for two reasons. Firstly, because most patients are very surprised at the cheapness of the present 1*s.* charge, and sometimes give me an extra amount out of gratitude. . . . When a town-hall is built I trust a proper room may be procured for me, with a recovery room away from the waiting room and the operating room in a north light." 0·28 per cent. of the routine children had pulmonary tuberculosis and 0·79 per cent. were classed as suspicious. No open-air class or school exists for the treatment of these cases. 12,027 school meals were supplied to 230 necessitous children. A plea is put up by Dr. Muir for the local education authority to make some arrangement with St. Bartholomew's Hospital, Rochester, whereby all crippling defects and orthopædic cases would have early and efficient treatment.

No special schools exist in the borough for the education of physically defective and mentally defective children. 1·9 per cent. of the intermediates and "leavers" were found to have visible enlargement of the thyroid gland. Measles, with 366 cases in 1924, as against 97 cases in 1920, was the only infectious disease showing an increase during the year.

Eccles.

Dr. J. E. Spence's report is a record of much work carried on by him unassisted except by a part-time dentist and a part-time ophthalmic surgeon. 8048 inspections is an imposing total for one man who also carries out the treatment in the minor ailment clinic, gives gas for the dentist, and supervises an open-air school, in addition to his work as M.O.H. The division of the work of the four nurses between school services and the public health side enables them to supervise infectious diseases, except scarlet fever and diphtheria, and since they also act as home nurses the confidence and sympathy of the parents are enlisted with beneficial results in the treatment of the school child. The welfare scheme is now coördinated with the school service and ensures continuity of supervision of children from infancy until they leave school, and the correction of remedial defects in infancy should result in a fall in the number of defects found amongst school entrants.

Stress is laid on the connexion between over-clothing (amongst other factors) and catarrhal conditions leading up to much invaliding from otitis and respiratory affections generally. Amongst the code groups 14·5 per cent. suffered from enlarged tonsils and adenoids, 14·1 per cent. from other nasal defects, and 15·7 per cent. from bronchial trouble; 74 children were found to have defects of the ears, and many children with defective hearing were found to have thickened and indrawn drums as sequelæ of old-standing catarrhal conditions. Though the number of verminous children has fallen this year, the number of those unclean had risen, and a slight increase in cases of blepharitis and conjunctivitis is reported. The school dentist examined 3752 children, of whom 2955 required treatment and 1186 were treated; 149 minor eye defects were treated at the clinic, and 162 were referred for refraction; glasses were prescribed in 123 cases, and obtained by 102 children. Six cases of organic heart disease and 130 cases of functional cardiac disturbance were noted. In view of the widespread interest now taken in rheumatism in its damaging effects on the heart, the past history of all cases of acquired organic carditis would be helpful.

The work of the open-air school is reviewed. The average gain in weight per child was 0·8 lb. per month. The cost per child to parents who can afford it is 5*s.* per week, and parents paid £283 3*s.* towards an outlay of £372 17*s.* for meals, medicine, car fares, &c. A table showing the length of stay, gains in weight, and general condition of each child in the open-air school is given. Apart from the open-air school 31 children who were ailing or convalescent were sent into the country under the auspices of the Manchester and Salford Children's Aid Association. No special schools as yet exist in Eccles for the education of physically or mentally defective children.

PORT SANITARY AUTHORITIES.

IN the letter introductory to his annual report for 1924 to the *Cardiff Port Sanitary Authority*, Dr. R. M. F. Picken, the medical officer of health, observes that, although no case of plague has occurred in Cardiff for many years, the chance of the spread of the disease has been a constant cause of anxiety. This was much accentuated in 1924 when a ship, which lay for a while in harbour during the summer, and was on arrival reported free from rats and "all well," and was later examined and "no rats found," was again inspected shortly before leaving and given a clean bill of health, and yet two cases of plague developed on board a fortnight later, the ship not having meanwhile touched at any other port. At Suez she was fumigated and ten rats killed. As a consequence ships are now inspected for rat infestation even more carefully than before. Dr. Picken saw two ships fumigated with hydrocyanic acid to destroy rats and thinks the method employed to be, in the hands of experts, without danger and the most efficient and expeditious means of freeing a ship from rats and all vermin. One small-pox patient, though discharged after treatment from a hospital abroad, was found on arrival at Cardiff to be still infectious; five of the crew were vaccinated and no subsequent cases occurred. The question of providing latrines ashore in sufficient numbers to permit the sealing of the water-closets of all ships in dock is under consideration. This very important matter came to the front in 1924 owing to the visits of naval vessels with large crews. In the report itself we find that the infectious diseases that came most frequently under notice were malaria 25 cases, pneumonia 11, and tuberculosis 5, or perhaps 17. There were no cases of cholera, plague, or yellow fever, and the hospital at Flat Holm Island, kept always ready for them, has been unused throughout the year. Many rats have been killed: in ships, by baits, 1480 (all black), averaging 39 per ship; by sulphurous acid 66, 9 per ship, and by hydrocyanic acid 44, 22 per ship; 4449 rats and 1097 mice were killed about the port by baits, and 437 in warehouses. Dead rats (104) were examined but none were plague-infected. On 214 rats examined for fleas, *Xenopsylla cheopis* was most frequently found, but never on rats from outside the port sanitary area; *C. fasciatus* was found on a rat caught in the town, and *X. brasiliansis* was found, for the first time in Europe, on a rat killed on board a ship from Brazil. The fleas were identified by Mr. J. J. Simpson, keeper of zoology, National Museum of Wales. The number of venereal cases attending the seamen's clinic for the first time (615) decreased in 1924 by a quarter, but the total attendances (16,212) increased by a sixth. Fifty of these cases were recommended for hospital treatment. Of scabies 26 cases were treated among seamen; no men were found verminous. None of the 354 aliens who passed through the port suffered from infectious disease. The lighters of the port have been examined, cleansed, and disinfected; the fishing boats and wharves have been regularly visited, cleansed, and disinfected. Inspections were made of 7086 vessels with 126,057 men in their crews. There were disinfected 887 articles of clothing and 1861 beds were destroyed. In 609 ships 1532 structural defects and other nuisances were detected, dirty quarters in 627, defective side lights in 298, 111 forecastles were verminous, 83 water-closets were dirty, 78 stoves in crew spaces were defective, in 50 cases water-closets or paint stores ventilated into crew spaces, and in another 50 the drainage of crew spaces was defective. Nearly all of these and the other 235 defects were put right, and the note in the report is correct that these figures prove useful work done by the staff of the authority and imply a great improvement in the sanitary surroundings of the seamen whose ships reach Cardiff. Ventilation and lighting are being improved, and dirt, smell, and dampness are being diminished. Defects were noted in less than 10 per cent. of the ships. Of 206 samples of drinking water from ships examined, 49 were condemned; the tanks concerned were emptied and cleansed. Some 350 tons of imported food, chiefly fruit, were condemned and destroyed. The sanitary condition of the canal boats is reported as on the whole satisfactory.

In his annual report for 1924 to the *Tyne Port Sanitary Authority*, Dr. W. E. Harker, medical officer of health, states that 82 vessels were visited by him on account of reported or suspected sickness on board; five cases of typhoid fever, one of diphtheria, and various slighter cases were removed and necessary disinfection done. No infectious disease was found among the 13,462 alien passengers, who were mostly clean. No case of plague, cholera, or yellow fever came under notice in 1924, but 5492 rats, none of them plague infected, were caught; 197 were killed with sulphur dioxide in 15 ships; hydrocyanic acid was not used. The dead rats were burnt in the ships' furnaces. Of the rats, two-thirds were black, one-third were brown; the largest number of rats caught in any month was 961 in October. Thirty-one ships from ports known or suspected to be infected with cholera had their drinking-water tanks emptied and purified. The chief diseases reported during the previous voyages or found on arrival were, accidents 197, venereal disease 122, feverish colds 114, undefined 96, malaria and influenza each 41, 10 cases of consumption, and 13 of typhoid fever with 5 deaths. The main imports into Newcastle were wheat, sugar, and other foods, of which there were condemned 1220 lb. peas, 10,898 lb. plums, 140 lb. potatoes, and three bags of wheat. The fish landed was good, but 35 of 8326 fishing vessels had to be cleansed and deodorised. In 10,076 inspections of ships, sanitary defects were found more often in foreign-going (13 per cent.) than in coasting (3 per cent.) ships. Peaks, forecastles, w.c.'s, and bilges of 1168 vessels, British and foreign equally, were found dirty and were cleaned. 1201 old beds were burnt. Structural defects were notified and rectified; side ports for refit 461, deck leaking 153, defective w.c.'s 135, defective stoves 36, water tanks cleansed 31, deficient ventilation 12, deck of forecastle for repair 7, paint (store) to be removed from bow locker 6, defects of drainage 6, of bulkhead 4, of lighting 1, and 1 iron deck was sheathed with wood. The 18 water boats of the port were examined and their tanks found in good condition. No master was summoned for evolution of dense smoke. The floating hospital is used for isolation and treatment of the more dangerous infectious diseases from abroad, also as a cleansing, disinfecting, and disinfesting station. Other infectious cases are sent to the city infectious hospital. The usual measures are taken for relief of venereal cases; there is no estimate of their usefulness.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED MAY 2ND, 1925.

Notifications.—The following cases of infectious disease were notified during the week, namely:—Small-pox, 176; scarlet fever, 1564; diphtheria, 769; enteric fever, 40; pneumonia, 970; puerperal fever, 45; cerebro-spinal fever, 10; acute poliomyelitis, 3; encephalitis lethargica, 55; continued fever, 1; dysentery, 7; ophthalmia neonatorum, 110. There were no cases of cholera, plague, or typhus fever notified during the week. The number of small-pox cases showed an increase of 6 over the number for the preceding week. Fifty cases were notified from Derbyshire (Derby C.B., 38); 11 from Northamptonshire (Kettering, 7; Desborough, 4); 38 from Northumberland (Prudhoe, 19); and 49 from Yorks, North Riding (Middlesbrough C.B., 45).

Deaths.—In the aggregate of great towns, including London, there was 1 death from enteric fever, 103 from measles, 11 from scarlet fever, 93 from whooping-cough, 25 from diphtheria, and 100 from influenza, as compared with 139, 162, 221, and 242 in the four preceding weeks. In London itself the deaths from influenza numbered 15, from whooping-cough 23, and from diphtheria 6.

Small-pox in Derby.—The medical officer of health of Derby reported to the town council on May 6th that the cases now numbered 147, compared with 102 last month. Since the outbreak in Derby in 1924, the great majority of the cases, he said, had been of the mild type. Recently there had been a larger proportion of a more severe type. The expenditure incurred during the financial year ended March 31st, 1925, was £5600.

Obituary.

THE LATE DR. REGINALD DUDFIELD.

Dr. Major Greenwood writes: "Absence from England when the lamentable news of Dr. Dudfield's death was received prevented me from adding a few words from the statistical side to your account of his career.[1] Dr. Dudfield was an important, in some respects the most important, member of the tiny group of English medical statisticians. He was the only senior member of the municipal public health service to whom statistical science was a principal interest. Others—it would be invidious to mention names—have, of course, done valuable statistical work, but Dudfield alone for more than a quarter of a century took a regular part in the work of the Royal Statistical Society, contributing many valuable papers to its journal and never grudging time and energy for the heavy work which has to be performed by the council and committees of a large scientific society. I have said that Dudfield was in some respects the most important member of our group. The reason is this. He was particularly interested in aspects of statistical work which *must* be studied if we are to progress, but which are not very attractive to most investigators. He was, indeed, a good investigator, as his paper on Epidemic Diarrhœa (read before the Epidemiological Section of the Royal Society of Medicine in 1912) proved; but his greatest energy and enthusiasm were reserved for the, as many think, dull work of reforming the basis of statistical investigation, rendering the data more precise. Most medical statisticians will recall his labours on the statistics of stillbirths, and if in this and in other countries more precise information on that topic is made available in the near future, Dudfield is the man to whom the reform will mainly be due. Within a few weeks of his death he attended at Geneva an international committee appointed by the Section of Hygiene of the League of Nations where this subject was discussed, and I have reason to believe that his share in the work of the committee was very large. 'I know the map of England, as well as the noble lord, or as any other person; and I know that the way I take is not the road to preferment.' Dudfield might have said that with as much justification as Burke. Patient and sagacious labouring to improve the raw material of statistics leads neither to academic honours nor to official promotion. But when, if ever, a true history of scientific progress is written, the name of Reginald Dudfield will be given precedence of names more often upon our lips. At least his old friends and colleagues in the work of the Royal Statistical Society and the Epidemiological Section of the Royal Society of Medicine realise how great a loss they have sustained."

HENRY TRENTHAM MAW, M.D. CAMB.

Dr. Henry Maw, chairman of directors of the firm of S. Maw and Sons, Ltd., manufacturers of surgical instruments and appliances, died on April 23rd at the age of 58. Dr. Maw was educated at Repton and Christ's College, Cambridge, and studied medicine at St. Bartholomew's Hospital, which he entered in 1890. He took the diplomas of L.R.C.P. Lond. and M.R.C.S. Eng. in 1892, and graduated M.B., B.C. Camb. two years later, gaining the M.D. in 1896. He held hospital appointments as house surgeon at the Leeds Infirmary and in London at the Children's Hospital in Great Ormond-street, and was for a time medical officer at the Royal Chest Hospital, City-road. Upon joining the firm, which was established by George Maw in 1807, Dr. Henry Maw took over the managership of the surgical instrument department, and continued to occupy that position until his death. He became a partner in the firm in 1901 and acted as chairman of the company from 1918. He was honorary treasurer of the National Union of Manufacturers and was also an official of the Surgical Instrument Manufacturers Association. Dr. Maw took infinite pains in all he did, and it was this quality associated with the will to please that assured his success in various walks of life.

DONATIONS AND BEQUESTS.—Miss Jane Ada Trenow, Richmond, Surrey, besides other bequests, left £1000 to the Zenana Bible and Medical Mission, and £500 to the Mission to Lepers in India and the East.—Miss Isabella Seymour, of South Eaton-place, London, S.W., and Aix-les-Bains, bequeathed £6000 to charities, including £2000 to St. George's Hospital, London; £1000 to the Belgrave Hospital for Children, Clapham-road, London, S.W.; and £1000 each to the Hôpital Etablissement des Baines (Roman Catholic), the Asile (Protestant), and Hospice Brachet, all at Aix-les-Bains.—The Christie Hospital, Manchester, has received £2500 from the executors of the late Mr. Edwin Kershaw, of Bolton, as payment on account of the residuary estate (amounting to about £4000) which Mr. Kershaw bequeathed to the hospital.—The students of Aberdeen University have raised fully £4000 on behalf of the hospitals in Aberdeen.—Miss Eliza Entwistle, of Longsight, Manchester, left £1000 each to the Manchester Children's Hospital, Ancoats Hospital, and the Christie Cancer Pavilion; £500 to the Ardwick and Ancoats District Nursing Home; £100 each to the Manchester Surgical Aid Society and the Disabled Folks Guild, Ancoats; and £350 to the Manchester and Salford Blind Society, subject to a life interest. The residue of the property to be divided between the Manchester Royal Infirmary, St. Mary's Hospitals, Manchester, and any other charitable institutions the executors may select.—The St. Mary's Hospitals, Manchester, have received £1500 from the executors of the late Mr. James Parr.

"Audi alteram partem."

THE ALLEVIATION OF CHRONIC PROGRESSIVE DEAFNESS.

To the Editor of THE LANCET.

SIR,—The interesting and instructive paper on the above subject published in your last issue by Mr. George C. Cathcart, calls for the serious attention of all otologists considering the almost invariably unfavourable result from treatment in cases of chronic progressive deafness whether due to pathological states of the auditory nerve or to chronic adhesive changes in the middle ear.

Modern surgery, with all its brilliant achievements, has up to now been unable to design any operative procedure which has afforded anything but a merely temporary improvement in those cases where definite thickening of the mucosa has taken place or where advanced adhesive changes have been noted clinically. One can understand that in cases of nerve deafness, where there is frequently a functional as well as an organic element, a certain improvement is possible by re-education with sonorous vibrations, but my difficulty is in grasping how advanced pathological thickening of the tympanic mucosa and stapedio-vestibular adhesions in cases of chronic dry catarrhal otitis media and pathological changes in the bony elements of the pars petrosa of a "porous" nature, as in otosclerosis, are capable of being materially altered by sound-vibration treatment even if a hyperæmia is induced as the result of mechanical sound waves of varying pitch and intensity.

The fact that 81 per cent. of Mr. Cathcart's nerve cases improved, whereas the improvement in the cases of chronic otitis media and otosclerosis was respectively 67 and 55 per cent., shows that the former are more prone to respond to this method of treatment than either of the other types of deafness. Is this due to the effect of the treatment or the frequently existing functional element?

I venture to suggest that Mr. Cathcart should continue his investigations and should experiment on certain deaf animals—e.g., dogs or cats—and after a course of treatment have a careful histological examination of the middle and internal ears made. If only it were possible to have the treatment based on sound pathological observations its reception by otologists would be more enthusiastic than it is at present. At the same time, I desire to say that the results presented by such a careful and conscientious observer as Mr. Cathcart is should not be too lightly dismissed even if at the present time pathological evidence of what actually does take place is not forthcoming. Otology has all along suffered from lack of pathological investigation, partly on account of the difficulty of securing good sections of the temporal bone, and more especially from the fact that patients do not die from such diseases as chronic catarrhal otitis media and otosclerosis.

Mr. Cathcart deserves great credit for his endeavours to do something to alleviate the hard and depressing lot of those whose hearing is so poor as to debar them from social intercourse.

I am, Sir, yours faithfully,
Manchester, May 10th, 1925. WILLIAM MILLIGAN.

CANCER AND INNERVATION.

To the Editor of THE LANCET.

SIR,—At the conclusion of a leading article on the Anatomical Distribution of Occupational Cancers allusion is made to Dr. W. Cramer's experimental support of my clinical observations on the relation of innervation to cancer. What can be the meaning of it all? Can it be that the presence of rodent ulcer acts as a stimulus that induces a dilatation of blood-vessels, which encourages its growth within the affected area? This does not appear to me to be the whole explanation, for many reasons that would take too long a letter to describe. The answer is complicated by realising that that which influences the spread need not necessarily affect the genesis of a rodent ulcer, although both its incidence and spread appear, from my clinical observation, to be very closely connected with the nervous system. It may suffice here to indicate that during one type of the natural acquirement of grey hair the greyness begins in beards on four points—viz., the two points where the mental nerves become cutaneous, and the two points where the great auricular nerves become cutaneous, thus making on the same beard four symmetrical points of beginning greyness, which cannot be a matter of accident or coincidence. As the greyness of the hair covering the skin and lower lip continues, an area exactly corresponding to the mental nerve area, as mapped out by Dr. Henry Head, is delimited by greyness. This appears to me a most interesting and profoundly important observation. It demonstrates a distinct relationship between an epithelial change (though it may be only one of loss of pigment), which is under an influence of the nervous system. Hair follicles, although near neighbours to each other, are really separate establishments, yet each is involved in this process of greyness within the nerve area under demonstration. Hence a nerve influence, or modification of nerve influence, upon the incidence and genesis of pathological new growth appears to me a very much more subtle thing than can be explained by only an alteration in the local blood vascular system.

There may be two distinct nervous influences in operation—one that concerns the incidence and genesis of rodent ulcer, and the other that affects only its spread. Now that Dr. Cramer's ingenious experiments have called attention again to the matter, I hope it will receive the attention I believe it deserves. I should like to remind you that I have shown clinical evidence that demonstrates a relationship between infective processes and nerve areas. Hence the question of acquired and natural immunity is also concerned in a local nervous relationship between host and the infective process.

I am, Sir, yours faithfully,
G. LENTHAL CHEATLE.
Harley-street, W., May 8th, 1925.

THE TREATMENT OF EXCESSIVE LOSS AT THE PERIODS.

To the Editor of THE LANCET.

SIR,—If to condemn utterly is better than to damn with faint praise, then the advocates of X ray treatment may be grateful to Mr. Victor Bonney for small mercies. In your issue of May 2nd, referring to cases of excessive bleeding in which no myomata are present, he says:—

> "X ray treatment is as much to be condemned in these cases as it is in cases of fibroids, under which heading I will refer to it more particularly."

After keeping the trembling radiologist in suspense for a whole week, he proceeds (THE LANCET, May 9th, p. 990) as follows:—

> "The treatment of fibroids by X rays I heartily condemn. It is, in effect, a revival of the bad operation of double oöphorectomy . . . in quite a number of cases neither the bleeding nor the growth of the tumour was checked (by this operation). X rays effect a bloodless oöphorectomy followed by results exactly the same and exactly as variable. . . . Moreover, I have seen irradiations followed by acute septic degeneration of the tumour, and by severe X ray burning of the abdominal wall. . . . The ideal surgical procedure cures without disturbing either function or normal structure."

Here, indeed, is strong doctrine—no subtleties—all plain black and white. How simple it would be if I could say ex cathedra that Mr. Bonney's black is white and his white black! But twenty-one years of practice, whether they have taught me much or little, have, at least, convinced me that truth is many sided, and I cannot oppose dogma to dogma. Nevertheless, I venture to assert (1) that any operation has a certain mortality; (2) that post-operative shock in a nervous patient is often severe and lasting; (3) that in some cases the excessive bleeding continues after the removal of the fibroids; and (4) that there are great numbers of cases on record in which a permanently satisfactory result has followed the treatment of fibromata by X rays.

It remains true that surgical removal is the treatment of election in women under 40, because, unless one produces an artificial menopause, it is impossible by X rays to reduce fibroids to permanent inactivity. After 40, X rays may be seriously considered as an alternative to surgery. *Pace* Mr. Bonney these effects are not simply those of a surgical oöphorectomy. The rays have an action on the tumours as such—temporary if the ovaries remain intact, but usually permanent if the ovarian activity is brought to an end. The power of X rays to cause *local* disappearances even of malignant tumours is not disputed, and it is surely not surprising that they can cause shrinkage of an innocent growth such as a fibroid. As to any disturbance which may follow an artificial menopause, the work of Groedel, Werner, and Borak[1] has taught us how to deal with these by checking the unbalanced action of the pituitary or the thyroid, on which they appear to depend.

The radiologist freely admits that, even in women over 40, there are many cases of fibromata which are unsuitable for X ray treatment. Large tumours should not be so dealt with as a rule, and the presence of sepsis or degeneration are contra-indications. In seeking to exclude these conditions he would be glad to have the aid of the gynæcologist —but is it in human nature that he should seek the coöperation of one who would like, metaphorically speaking, to burn him and his writings at the stake?

Mr. Bonney's reference to skin damage by X rays after sterilisation cannot be accepted in these days as a valid objection, provided that the treatment is carried out by a competent radiologist. Up to three or four years ago it was necessary to give a "full skin dose"—i.e., a dose just short of that producing a definite erythema—in order to get a sufficiency of radiations into the ovaries. Now, with improved apparatus and technique, only one-third of this is essential on any given area, which leaves a margin of safety of over 60 per cent. The X ray treatment of fibroids is admittedly of limited applicability. I will not venture to express an opinion as to what proportion of all cases are suitable. It is, indeed, impossible for any radiologist to obtain the data upon which an estimate could be based. It is equally impossible for the gynæcologist to judge of the successes of X ray treatment; he sees only the failures, just as the surgeon does in the case of Graves's disease. On the other hand, to the radiologist come some of the patients whom myomectomy has failed to relieve from the excessive losses on account of which they originally sought advice. To attempt to judge the value of the operation of myomectomy from a consideration of such cases would be manifestly unfair.

I now pass from this debatable ground to the use of X rays in cases of excessive bleeding where no tumours can be found. Such lesions as retroversion of the uterus or erosion of the cervix may be present, but operation should not be recommended for these conditions with a promise that the hæmorrhage will be benefited, as often it is not. Excessive menstrual bleeding often occurs in virgins, and may be accompanied by no detectable abnormality. It may then be termed "idiopathic" and appears to be associated with excessive production, or vitiation, of the ovarian hormone; it is amenable to the same type of radiation treatment as is so often successful in exophthalmic goitre. X rays in small repeated doses have the power of regulating thyroid secretions without in any way damaging the gland. It is never justifiable to push X ray treatment of the thyroid to the point of injuring it; and the same holds good with regard to the ovaries in the treatment of menstrual disorders in young women. I will now, in my turn, be mildly dogmatic, and say that X rays, properly applied, have an almost specific effect upon "idiopathic" excess at the monthly periods. They may also, in some cases, relieve painful menstruation when bleeding is not a prominent feature; but their sphere par excellence is in dealing with hæmorrhage. This is not the place to quote cases, but anyone interested may refer to my paper on the subject in THE LANCET (1919, ii., p. 432).

The crude idea of destruction—even selective destruction—is quite out of date in radiation therapy. That of *regulation* is taking its place, especially with regard to the functions of the ductless glands. We know that we can by X rays check excessive activity of the thyroid, ovaries, or pituitary. We can stimulate the thyroid by electricity, and there is some ground for believing that adrenal secretion is increased by ultra-violet rays. The X ray treatment of endocrine disorders—under which heading must be included many forms of menstrual disturbance—is not in any sense bloodless surgery, but a rapidly progressing branch of physiological therapeutics.

I am, Sir, yours faithfully,

F. HERNAMAN-JOHNSON.

TREATMENT OF ACUTE PERITONITIS.

To the Editor of THE LANCET.

SIR,—In the excellent article on this subject printed in your issue of April 4th the principal traits of the diagnosis of the disease are touched upon. I shall take the liberty to make some additions to the diagnostical procedures proposed by Mr. Jeans and mentioned also by Mr. Zachary Cope.[1] Both of them advise in cases of difficult and doubtful diagnosis the making of a short exploratory incision of the abdominal wall. I am also of this opinion, but since the exact microscopic analysis of any peritoneal fluid is of great importance, I make only a very small incision in the abdominal wall, not only in order to see and smell the escaping liquid, but also to withdraw some of the fluid by means of a pipette introduced into the cavity and to subject it to microscopical examination. In my experience the cells in the normal peritoneal fluid are 70 per cent. lymphocytes. In cases even of early peritonitis the ratio of lymphocytes to other forms of cell becomes much smaller. Besides this, in cases of peritonitis caused by small perforations the contents of the organ perforated may be found. In very early cases, where there may be very little fluid, it is useful very gently to scrape the peritoneal contents of the parietal peritoneal wall with a spoon. This practice is adopted by me only in difficult and early cases and has proved to be a very useful guide. In a paper read before the Congress of Surgeons of South Russia in Odessa in 1924 I named this little operation *laparotomia minima*. It is performed under novoçaine anæsthesia. The place of incision, in my opinion, is not of great importance, but it is better to cut in at the point of the supposed source of infection. The operation can be performed in bed. The length of incision required depends on the amount of subcutaneous fat, but need never exceed one inch. Simple puncture of the abdomen must be avoided, owing to the danger of perforating distended intestine.

I am, Sir, yours faithfully,

SERGE LIGIN,

Surgeon at the Labour Hospital, Nikolajeff,
South Russia.

April 27th, 1925.

[1] THE LANCET, 1924, ii., 806.

THE Twelfth International Physiological Congress will take place in 1926, at Stockholm, from August 3rd to 6th. The Congress will be under the presidency of Prof. Johansson. Prof. Liljestrand will be hon. secretary and Prof. Santesson hon. treasurer.

HEALTH INSURANCE IN THE IRISH FREE STATE.

An Interim Report of the Committee of Inquiry into Health Insurance and Medical Services in the Free State was issued last week. The Committee was constituted as follows: Prof. J. B. Magennis (chairman), Sir Joseph Glynn, Canon McHugh, Dr. W. J. Maguire, Dr. R. J. Rowlette, Dr. E. F. Stephenson, Mr. James Hurson, Mr. James G. Kydd, and Mr. J. J. McElligott, with Mr. W. J. Kavanagh (secretary). With the exception of the Chairman, Canon McHugh, and Dr. Rowlette, the Committee was composed of officials concerned with National Health Insurance or Local Government work.

Terms of Reference.

Appointed in May, 1924, the Committee was asked (1) to inquire into and report on the advisability of the continuance of the present system of National Health Insurance, and to make any recommendations which the Committee considers proper in that connexion; (2) to consider whether it is desirable to institute a system of medical treatment on a contributory basis, and, if so, to advise as to the form which such system should take; and (3) to examine and report on the question whether the medical services at present assisted or maintained out of State or local funds can be improved as respects efficiency and economy, and, if so, in what manner, due regard being had to any recommendations made under the preceding paragraph.

A large number of witnesses were examined, including representatives of the Government departments concerned, the approved societies, the Labour Party, the medical profession, and the local authorities. The Interim Report is concerned mainly with the first of the terms of reference, and deals only in general terms with the second and third. The Committee received an overwhelming body of evidence in favour of the continuance of National Health Insurance in the Free State.

High Cost of Administration.

Certain points in the present administration of health insurance received special study. The cost of central administration appears abnormally high, in that it costs 3*s.* 8½*d.* per insured person in the Free State, as compared with 1*s.* 4*d.* in England. The Irish Commission submits that the method of calculating the expense at cost per head of the insured population is misleading and unfair; for it points out that there are over 12½ millions of insured persons in England compared to 450,000 in the Saorstát, and that the overhead charges must be greater proportionately to numbers in the Saorstát than in Great Britain for administering the same type of machine. There are, moreover, other reasons why the cost of central administration is relatively higher in the Saorstát than in Great Britain. Among others it appears that compliance in Great Britain, excluding domestic servants, is about 99 per cent. of the insured population. In the Saorstát the total, without exclusions, is only from 65 per cent. to 70 per cent. Non-compliance creates increased work for the Commission's staff. For the ten years ended March, 1924, the Irish Commission dealt with 15,200 disputed transfers. In the same period Great Britain, with an insured population 18 times that in Ireland, dealt with only 50,000 disputed transfers. From January, 1922, to Sept. 30th, 1924, in England with 12½ millions of insured people there were only 62 appeals. The Insurance Commission in the Saorstát with 450,000 insured persons dealt with 81 appeals. In Scotland with four times the Irish insured population there were only 44 appeals and in Wales no appeal until 1918. The Committee adopts the view that if there were proper compliance with the provisions of the Insurance Act the cost of central administration could be largely reduced. The main fact which emerges on this point is that the Insurance Organisation as set up in 1911 in Ireland is costly because it copies exactly that set up for Great Britain which, apart from its greater wealth, has a huge industrial population concentrated in convenient centres.

As regards compliance, the Committee believes that with the re-establishment of ordered conditions throughout the country compliance will become more general. The Committee recommends that greater powers should be given to the inspectorial staff of the Insurance Commission and that a publicity campaign should be organised to bring the benefits of the Acts before those for whom specially they were designed. Among some minor reforms the Committee recommends that the period during which notice of illness should be given by an insured person should be extended from three to seven days.

Approved Society Control.

The majority of the Committee recommends a very radical reform in the system of administration of health insurance—the amalgamation of all approved societies into one society. A strong case is made against the existing system, under which administration is in the hands of some 80 approved societies. It is said that there is overlapping of societies, inequality of benefits, lack of uniformity of administration, unnecessary expense both in the societies and in the office of the Commission. It is noted that the representatives of the approved societies (with the exception of the trade societies) were opposed to any radical alteration of the present system of administration by approved societies. The representatives of the Irish Labour Party and of the Trade Union Approved Societies, on the other hand, were in favour of a scheme of nationalisation, but failing that nationalisation, were willing to accept unification. Dr. Rowlette dissents from the majority of the Committee in regard to this recommendation, and in a separate note recommends that the whole system of insurance should be nationalised and committed to the care of a department of Government.

Advantages of Nationalisation.

Dr. Rowlette believes that such concentration in a Government department would have the following advantages: (1) The direct responsibility of a Minister to Parliament for the entire administration of National Health Insurance. (2) The coördination of National Health Insurance with the health policy of the country, and with the whole scheme of preventive medicine. (3) The possibility of readily fitting in National Health Insurance with any other form of social insurance which the country may decide to adopt in the future. (4) A greater immediate economy than can be attained, without loss of efficiency, by any other method. Even if there were to be only one approved society, he suggests, as the majority of the Committee recommends, there would still be considerable duplication of duties, as identical records on certain matters must be kept by the society and by the Commission or controlling authority. Such duplication would disappear if all administration were merged in one body. He further suggests that the creation of a society comprising in its membership all the insured persons in the Free State would not be free from danger. Such a society would be so large and so powerful that it would be beyond the control of either the official supervising authority or of the Oireachtas. It would be to the interest of such a combine to gain a power on each of the parties of the State, and to attempt to pervert Government at its source. So far from the diversity of elements in the society tending to prevent its exercising a political power, the fact that it contained very diverse elements would give it all the greater power in the underworld of politics. Moreover, the farming out of health insurance to a society created for the purpose would appear to be a mere shelving of the responsibility belonging to the State itself. In the words of one of the witnesses, "Unification would be nationalisation without responsibility."

Provision of Medical Benefit.

In reference to the second of the terms of reference, the Committee points to previous recommendations in favour of the provision of medical treatment for insured persons in Ireland, and it recommends, Mr. McElligott dissenting, that medical treatment on a contributory basis should form part of National Health Insurance. The Committee recognises, however, that the provision of medical benefit is mainly a problem of finance, and in the absence of fuller information as to the funds that may become available from insurance sources (in addition to those at present devoted from various sources to purposes of medical treatment), and as to the position which such arrangements would occupy in relation to the medical charities system, is unable in this interim report to formulate a scheme for the provision of medical treatment. It is hoped, however, that the valuation of the approved societies, the preliminary operations of which are at present proceeding, will be sufficiently advanced by the autumn of this year to enable definite recommendations to be made on the second—as well as on the third—of the terms of reference.

Present Medical Services.

In reference to the third of the terms of reference, the Committee reviews the present medical services of the country, and makes some sharp criticisms of the dispensary medical services. It admits that the present system of appointment is objectionable and sometimes corrupt, and that "the members of local authorities are not always competent to decide the merits of professional candidates." It is admitted, too, that many of the dispensary buildings are unsuitable. The increase of salaries, as shown by the average figures for the year ending March 31st, 1924, as compared with the figures for 1904—admitted to be grossly inadequate—is more apparent than real, owing to the greatly increased cost of living. The Committee recommends that provision should be made for "study leave" for dispensary medical officers.

A National Medical Service.

The report closes with a summary of the recommendations previously made in favour of a National Medical Service, and states that for a number of years there has been a growing volume of opinion in favour of such a service. Definite recommendations on this point are not made in the interim report, but the subcommittee is to consider the entire matter in the light both of past reports and of existing conditions and thus, it is hoped, enable the Committee to frame a comprehensive scheme which, under some form of national medical service, will combine the medical treatment of the insured with the medical treatment of the poor.

Mr. McElligott does not sign the general report, though he agrees with many of the recommendations. He dissents from every recommendation in favour of medical treatment until there is fuller knowledge from the financial side.

THE BATEMAN APPEAL.

As already explained in THE LANCET, it has been felt that material assistance ought to be offered to Dr. Bateman to meet the legal expenses of his recent successful appeal against conviction and to make good the deficiency in his professional income. Accordingly, the Bateman Fund has been opened and lists of contributions have appeared in recent issues. We have received additional contributions as follows:—

	£	s.	d.
Already received and acknowledged ..	436	13	6
Mr. W. C. Bull	5	0	0
Dr. A. G. Andrews	1	1	0
Dr. M. A. Collins	1	1	0
Dr. E. Fisher	1	1	0
Dr. Geoffrey Noott	1	1	0
Dr. A. Graham-Stewart	1	1	0

Remittances should be forwarded to the Manager of THE LANCET, 423, Strand, W.C. 2, and made payable to the "Bateman Fund Account."

LISTER INSTITUTE OF PREVENTIVE MEDICINE.

THE annual report of the governing body of the Lister Institute for the year 1924–25 includes brief summaries of work done in the six departments of the Institute under the general direction of Prof. C. J. Martin, F.R.S., and a brief note on the work of the National Collection of Type Cultures (Medical Research Council) which is housed in the Institute under the supervision of Prof. J. C. G. Ledingham, F.R.S.

We can only indicate a few of the important investigations which have been undertaken in the several departments.

In the department of *Bacteriology* Prof. Ledingham has continued his study of the virus of vaccinia and avian molluscum, and is investigating material from cases of the mild small-pox now prevailing in England. Dr. J. A. Arkwright has continued his work on bacterial variation and the bacteriophage phenomenon in association with Dr. S. S. Zilva. Dr. Arkwright has also studied the inflammatory reaction produced by irritants in guinea-pigs and in rats, with special reference to the influence of bad nutrition on the intensity of the reaction. In young growing animals the influence is obvious, and an attempt is being made to identify the dietary factors on which a large inflammatory reaction depends. Dr. S. P. Bedson has investigated the effect of splenectomy on experimental purpura in guinea-pigs. He concludes from his experiments that the spleen plays no essential rôle in the production of purpura, and suggests that splenectomy cannot be relied upon to give permanent relief in the treatment of purpura hæmorrhagica. Dr. H. L. Schütze has carried out a series of immunity tests in guinea-pigs with various plague prophylactics in view of the considerable demands on the Institute for plague vaccine for use abroad. A vaccine prepared by the Institute method, using agar flushed with serum, was tested against Haffkine's prophylactic on guinea-pigs and yielded a survival percentage of 44 per cent., Haffkine's prophylactic yielding only a 14 per cent. survival rate. The dose of *B. pestis* administered to the immunised guinea-pigs was that which killed 100 per cent. of control animals.

In the department of *Biochemistry*, under the direction of Prof. A. Harden, F.R.S., experiments bearing on the conditions under which the enzyme in living yeast and in yeast preparations exists are being undertaken. The conditions under which fat and carbohydrate are synthestised by vegetable organisms are being studied by Dr. Smedley Maclean. Since the benefit ascribed to chaulmoogra oil, its soaps or ethyl esters in the treatment of leprosy had led to the recommendation of similar compounds as a remedy in tuberculosis, experiments upon the value of chaulmoogra oil in the treatment of tuberculosis have been carried out in this department. Dr. Schütze and Dr. Zilva find that soaps of chaulmoogra oil, although they have a very decided bactericidal action on the tubercle bacillus in vitro, do not perceptibly impede development of the bacillus in vivo.

In the department of *Experimental Pathology* a great deal of work is being done on the vitamin contents of milk, cod-liver oil, green leaves, and other substances, by Dr. Harriette Chick, Dr. Ethel M. Luce, Miss M. A. Boas, and their colleagues. Dr. Chick is endeavouring to ascertain to what extent plants are dependent upon sunlight for the manufacture of vitamin A and anti-rachitic vitamin respectively. The first question has practical importance connected with the feeding of cattle designed to provide food in the form of meat and milk. The second has a wide scientific significance in regard to the origin of fat-soluble vitamins in nature. The inter-relation of vitamins and ultra-violet radiations is the subject of study by Miss E. H. Hume and Miss H. H. Smith. Dr. T. Lumsden's tissue culture work is familiar to our readers (THE LANCET, 1924, ii., 65; 1925, i., 383).

In the department for the *Study and Preparation of Antitoxic Sera*, an infection attacking the breeding stock of guinea-pigs, which occurred during the latter part of the year, led to a study of puerperal infection among these animals. The breeding sows alone were infected; the boars and young animals were exempt. Deaths occurred within a week or so of kindling down. The disease appears to be a chronic one, but becomes acute post partum. A pneumococcus was readily isolated from the heart blood and uterus of fatal cases, and in some instances from pneumonic patches in the lungs. It was also found in the fœtus. With the object of producing an active immunity the whole stock of guinea-pigs was treated with a multivalent vaccine prepared from the strains isolated. The results were encouraging.

In the department for the *Preparation and Study of Anti-Variolous Vaccine* at Marazion, Cornwall, Dr. A. P. Green has been studying the reaction of animals to revaccination. As found by Pirquet and Prowazek some years ago, an accelerated reaction was observed. This allergic response occurred about 24 hours after inoculation and was characterised by marked erythema and slight swelling at the seat of inoculation. The effect was transient. It was observed in all the animals experimented with. The occurrence of an accelerated reaction to vaccination has been recommended for the diagnosis of doubtful cases of small-pox, but in view of the above observations its applicability would appear to be confined to unvaccinated persons.

Foot-and-Mouth Disease.—In August last the governing body of the Institute agreed to place one of its laboratories, together with a suitable isolated and self-contained animal house, at the disposal of a committee appointed by the Ministry of Agriculture to investigate foot-and-mouth disease. The committee is presided over by Sir William Leishman, and includes Prof. W. Bulloch, Prof. C. J. Martin, and Dr. Arkwright among its members. Dr. Bedson has been seconded to work under the committee, and Dr. H. B. Maitland and Mrs. Burberry have been appointed to work with Dr. Bedson. The work is under the general supervision of Dr. Arkwright.

Financial Position of the Institute.—The total expenditure for the year was some £37,500, a decrease of about £6000 on that of last year. Of this sum, over £30,000 was obtained from the sale of sera, vaccines, and stock, and another £3600 from investigation, diagnosis, and analysis fees. The Institute has other sources of revenue in the way of interest and dividends on general investments, and the accounts show a balance of excess of income over expenditure of £11,000.

ROYAL COMMISSION ON NATIONAL HEALTH INSURANCE.—The twenty-seventh meeting of this Commission was held at the Home Office, Whitehall, on May 7th, Lord Lawrence of Kingsgate in the chair. Evidence was continued on behalf of the British Medical Association by Dr. R. A. Bolam, chairman of the Council, Dr. H. B. Brackenbury, chairman of the Representative Body, Dr. H. Guy Dain, chairman of the Insurance Acts Committee, Dr. Alfred Cox, medical secretary, and Mr. N. Bishop Harman, hon. treasurer. The following subjects were dealt with: The procedure for dealing with complaints against doctors, the work of medical institutions under Section 24 (4) of the Act, the need for a unified local health service and the administrative and financial arrangements in connexion therewith, the arrangements for the additional treatment benefits. Dr. Stanley Hodgson, chairman of the Salford Panel Committee, gave evidence on the Manchester and Salford method of payment of doctors on an attendance basis. Dr. J. P. Williams-Freeman, chairman of the Hampshire Panel Committee, gave evidence on the peculiar conditions of rural areas. Thereafter evidence was given on behalf of the Medical Practitioners' Union by Dr. Gordon Ward, Dr. E. A. Gregg, Dr. A. Welply, Mr. Charles Davis, and Mr. S. G. Davis on the various features of medical benefit under the insurance scheme and proposals for extension of that service. Proof copies of the oral evidence and the relative statements submitted at the meeting of April 23rd are now on sale at H.M. Stationery Office (2*s.* 3*d.*).

The Services.

Surg. Vice-Admiral J. Chambers, C.B., C.M.G., Director-General of the Medical Department of the Royal Navy, has been appointed an honorary physician to the King in the place of the late Surg. Vice-Admiral Sir Arthur W. May, K.C.B.

ROYAL NAVAL MEDICAL SERVICE.

Surg.-Comdr. L. Lindop is placed on the Retd. List with the rank of Surg. Capt.

ROYAL NAVAL VOLUNTEER RESERVE.

Proby. Surg. Lt. H. Nichol to be Surg. Lt.

ROYAL ARMY MEDICAL CORPS.

Maj. and Bt. Lt.-Col. J. G. Bell to be Lt.-Col., vice Lt.-Col. and Bt. Col. H. Ensor, promoted.

Maj. W. C. Nimmo is placed on the half pay list on account of ill-health.

Capt. L. T. Poole to be Maj.

SUPPLEMENTARY RESERVE OF OFFICERS.

Capt. J. A. Charles, from Reg. Army Res. of Off., R.A.M.C., to be Lt.

TERRITORIAL ARMY.

Surg. Lt. A. C. Ballance (late Royal Navy) to be Capt.

Capt. E. B. Keen to be Maj. (Prov.).

Capt. H. B. Logan resigns his commn. and retains his rank.

TERRITORIAL DECORATION.

The King has conferred the Territorial Decoration upon Col. F. G. Proudfoot; Lt.-Cols. R. M. Vick and Sir Ewen J. Maclean; Majs. R. Coffey, E. J. Boome, D. S. Sutherland, and A. E. Webb-Johnson.

ROYAL AIR FORCE.

Flight Lt. J. K. R. Landells is granted a permanent commission, Flying Officer J. B. Gregor is promoted to the rank of Flight Lt., and Squadron Leader J. H. Wood relinquishes his temporary commission on ceasing to be employed.

INDIAN MEDICAL SERVICE.

Majs. C. E. Palmer, C. H. Reinhold, W. D. Wright, J. F. Boyd, V. N. Whitamore, and W. J. Powell to be Lt.-Cols.

The King has approved the retirement of Majs. C. H. Cross (on account of ill-health) and J. A. Cruickshank.

On return from leave Lt. C. Mullins has been appointed Civil Surgeon, Lushai Hills. Major J. D. Sandes, officiating professor of clinical medicine, Medical College, Calcutta, and second physician to the College Hospitals, has been appointed to act as Principal and Professor of Medicine, Medical College, Calcutta, and First Physician, College Hospitals, vice Lt.-Col. F. A. F. Barnardo, granted leave. The Viceroy has appointed Col. L. F. Smith and Lt.-Col. E. P. Sewell to be Honorary Surgeons on his personal staff, vice Lt.-Col. E. Kyan and Brevet-Col. F. S. Irvine. The following postings of Civil Surgeons in the United Provinces of Agra and Oudh have taken place: Capt. A. Seddon to Saharanpur. Lt.-Col. M. R. C. MacWatters from Shahjahanpur to Meerut; Major R. S. Townsend from Jhansi to Bareilly; Dr. F. W. Holmes from Fatehpur to Gonda; and Dr. H. G. Mathur from Lucknow to Unao. Capt. G. H. Mahony, whose services had been placed temporarily by the Government of India Department of Education, Health, and Lands at the disposal of this Government, has been appointed to be Civil Surgeon and posted to the Amaoti district. The following officers have been granted leave: Lt.-Col. W. D. Richie, civil surgeon, Darrang; Major B. E. M. Newland, civil surgeon, Saharanpur; Lt.-Col. T. Hunter, civil surgeon, Lucknow Lt.-Col. E. C. Hepper, civil surgeon, Bareilly; Major C. H. Reinhold, civil surgeon, Meerut; and Major R. Knowles, professor of protozoology, School of Tropical Medicine and Hygiene, Calcutta. The Chancellor of the Patna University has nominated Lt.-Col. James Masson to be an ordinary fellow of the Senate of the Patna University, vice Col. H. Ainsworth, who has vacated his seat. Lt.-Col. J. D. Graham, Public Health Commissioner, is attending the meeting of the Office International d'Hygiène Publique at Paris as the representative of British India. He will also attend another meeting in London in connexion with matters arising out of the pilgrim traffic with Mecca. The first and principal item of the agenda of the Paris meeting is the project of revising the International Sanitary Convention of Jan. 17th, 1912. Lt.-Col. J. R. J. Tyrell, agency surgeon, acts as Political Agent during the absence on leave of Lt.-Col. G. H. Anderson.

Parliamentary Intelligence.

HOUSE OF LORDS.

Wednesday, May 6th.

The Use of Liquid Milk.

Viscount **Astor** asked whether the Government proposed to take administrative steps to stimulate the dairy industry and increase the use of liquid milk. Milk was the prime food of children, and its consumption in this country was only one-sixth of what it was in Switzerland and one-third of what it was in the United States. They ought to set out to improve the quality of milk in the next ten years. A great deal of the milk sold in London and other large cities had been partially pasteurised; that was a fraud on the public. There was great merit in sufficiently pasteurised milk, but he could see no argument in favour of partially pasteurised milk being sold as raw milk. A new and proper classification of milk was needed. Between 1871 and 1914 the population of this country increased by 60 per cent., but the number of cows only increased by 40 per cent. Between 1914 and 1924 the increase in the number of cows was only 5 per cent., while imports of condensed and dried milks and milk foods increased by 80 per cent.

Lord **Bledisloe** (Parliamentary Secretary, Ministry of Agriculture) said the Government recognised the extreme importance of the problem, but they feared lest in endeavouring to secure pure and disease-free milk for human consumption they might take steps which would tend to dry up the milk-supply altogether, or bring about a milk famine. They deplored the fact that consumption here was less than in other countries, but it was no good passing drastic laws if public opinion was not ripe to endorse them. The sad fact was that neither was the general public alive to the importance of pure milk, nor were farmers sufficiently appreciative of the need to be up to date in their methods compared with other countries to eliminate from their herds unsound cattle and to employ the cleanest possible methods of milk production. A good deal, however, was being done to educate both the public and the farmers.

HOUSE OF COMMONS.

Wednesday, May 6th.

Infection in Public Libraries.

Mr. **Groves** asked the Minister of Health whether his attention had been called to the danger of infection to the frequenters of public libraries through the use of books previously handled by persons suffering from infectious ailments, or books having been in homes where infectious ailments had developed; and whether he would consider taking special steps to investigate these possible dangers to public health by calling the attention periodically of local authorities to the need of the utilisation of adequate disinfectants in the public libraries.—Sir **Kingsley Wood** (Parliamentary Secretary to the Ministry of Health) replied: The answer to the first part of the question is in the affirmative, but my right hon. friend is advised that medical officers of health are fully alive to whatever danger of infection there may be from this source. Special provisions as to the precautions to be taken to prevent the spread of infection through the use of library books are contained in Section 59 of the Public Health Acts Amendment Act, 1907, and that section may be put in force in any district on the application of the local authority. In the circumstances my right hon. friend does not consider it necessary to undertake any special investigation or to issue any periodical instructions to local authorities on this matter.

Prohibition of Drugs in India.

Mr. **Cecil Wilson** asked the Under-Secretary of State for India whether his attention had been called to the report of the Bombay excise committee, in which it was recommended that prohibition of drink and drugs should be completed as early as possible; and whether, as the Bombay Government had passed a resolution upon the report to the effect that serious efforts should be made to surmount the financial and administrative difficulties, he could arrange for a copy of the report and of the resolution to be placed in the library.—Earl **Winterton** replied: The attention of my noble friend has been drawn to the report and resolution. The resolution adopts the recommendation of the committee that the Government should declare that the total extinction of the traffic in alcoholic drink and drugs by suitable steps is the goal of their excise policy, and states, in the words quoted by the hon. Member, that a serious effort should be made to surmount the difficulties, both financial and administrative, which stand in the way of the adoption of such a policy. It also outlines the action which the Government propose to take in the immediate future. A copy of the report and resolution will be placed in the Library of the House.

Protection from Anthrax.

Colonel **Day** asked the Home Secretary whether he was aware of the fact that, at a recent inquest held in Southwark, it was proved that the death of a docker was found to be due to anthrax, contracted through dust rising from dry hides; were all the statutory precautions being taken at wharves where these hides were handled; and was he prepared to issue an Order for the compulsory sterilisation of all hides, with a view to minimising in every possible way the danger of anthrax infection.—Sir W. **Joynson-Hicks** replied: There have been two recent cases in this area. The statutory precautions applicable are those contained in the Hides and Skins Regulations made under the Factory and Workshops Act, 1901, and the Chief Inspector of Factories informs me that these are in general well observed, and that neither of the cases referred to was due to any breach of the regulations. I regret that it is not practicable to issue an Order as suggested, as there is at present no known effective method of sterilising hides which does not seriously damage them for commercial purposes.

Blind Persons in England and Wales.

Captain **Fraser** asked the Minister of Health how many blind persons over the age of 16 there were in the United Kingdom; how many of these were in the workhouses; how many lived in institutions and hostels for the blind; and how many in each of the above categories were totally blind or so blind as to be unable to do work for which eyesight was essential, respectively.—Mr. N. **Chamberlain** replied: According to the most recent returns, there are in England and Wales 33,564 blind persons over 16 years of age. Of these, it is estimated that approximately 3000 are in workhouses or workhouse infirmaries, 638 blind persons are resident in homes for the blind, and 190 in hostels. No statistics are available for the classification of these blind persons in the manner suggested in the last part of the question.

Mr. **Robert Young** asked the Minister of Health the total number of blind persons in England and Wales respectively; and how many of these men and women were in receipt of an old age pension from 50 years of age and upwards.—Mr. N. **Chamberlain** replied: According to the most recent returns there are 36,518 blind persons in England and Wales. On March 31st last 12,024 of those persons between the ages of 50 and 70 were in receipt of the old age pension. Blind persons over 70 receive the old age pension on the ground of age and not of blindness, and no separate figures are available for this group.

Thursday, May 7th.

Patients' Strike at Roehampton Hospital.

Colonel **Day** asked the Minister of Pensions whether his attention had been drawn to the recent strike of the inmates of the Ministry's institution, Queen Mary's Hospital, Roehampton, arising out of the stoppage of week-end leave; and was he prepared to cause instructions to be given at this and other similar institutions that come under his authority that in future full facilities for week-end leave would be afforded those patients who were deemed medically fit for travelling and who were desirous of visiting their families.—Major **Tryon** replied: I have inquired into this matter and I find that a number of patients to whom the medical superintendent found himself unable to grant leave deliberately absented themselves without permission. The hon. Member will realise that these men are in hospital solely for the purpose of treatment with the object of improving their condition, and that, in considering any question of leave, regard must be paid to the requirements of the treatment prescribed and to the effective management of the institution. I may point out that the facilities granted are considerably in excess of those allowed by civil hospitals. I see no reason to alter the existing leave regulations which are working satisfactorily at other Ministry hospitals.

Pensioners and Treatment Allowances.

Mr. **Windsor** asked the Minister of Pensions whether, seeing that in the Supplementary Vote for that Ministry provision was made for an additional sum of £920,000 in respect of the payment of treatment allowances in excess of pension, why there was a reduction in the Estimates for the year 1924–25 of £1,140,500 in the provision for treatment and treatment allowances, of which sum practically £500,000 was in respect of allowances in excess of pension; and whether any instructions had been issued to the medical officers of the Ministry that they should as far as possible reduce the number of cases in which allowances should be paid even though the pensioner might be totally disabled, temporarily, as the result of his war disability.—Major **Tryon** replied: If the hon. Member will refer to the Supplementary Estimate for my department he will see that of the £920,000 mentioned in the first part of the question only £430,000 was in respect of treatment allowances. The reduction in the estimates for the cost of treatment during the present financial year anticipates a continuance of the decline in our requirements for treatment which has been a normal feature of pensions expenditure for several years past. No change has been made in the conditions of eligibility for treatment allowances and no instructions in the sense suggested by the hon. Member have been issued.

Separate Existence of Pensions Ministry.

Mr. **ROBINSON** asked the Minister of Pensions whether he had under consideration proposals to transfer the Ministry of Pensions to the Ministry of Health and for the termination of the Ministry of Pensions as a separate department in 1927.—Major **TRYON** replied: No, Sir; the Government have no such proposals under consideration.

Bursitis as an Industrial Disease.

Mr. **TINKER** asked the Home Secretary what decision he had arrived at in regard to the inclusion of bursitis in the schedule of industrial diseases for miners' beat-knee.—Sir W. **JOYNSON-HICKS** replied: No decision has yet been arrived at. As the hon. Member is perhaps aware, a committee of the Medical Research Council has submitted a report on miners' beat-knee, beat-hand, and beat-elbow, and the question—which is a very technical one—whether any alterations in the present descriptions of these injuries are necessary is being carefully considered in the light of that report. The information in regard to the case which the hon. Member brought to my notice will also be taken into account.

Edinburgh Production of Morphia, Heroin, and Codeine.

Lieut.-Commander **KENWORTHY** asked the Home Secretary how much, respectively, of morphia, heroin, and codeine was made by the two factories in Edinburgh in the year 1924; how much of each of these drugs was exported by British firms; where they were sent; and how were they despatched, whether shipped or sent by parcel post.—Sir W. **JOYNSON-HICKS** replied: The statistics for 1924 are not yet completed, but I can give provisional figures. The two manufacturing firms made 99,400 oz. of morphine, 16,700 oz. of heroin, and 153,300 oz. of codeine. 88,870 oz. of morphine were exported, but this figure includes the morphine contained in preparations made direct from raw opium. 10,704 oz. of heroin were exported. Statistics of the exports of codeine are not available. The destinations of the exports were approximately as follows: Europe received 60,000 oz. of morphine and 7600 oz. of heroin; Asia 12,500 oz. of morphine and 600 oz. of heroin; Africa 1400 oz. of morphine and 140 oz. of heroin; North and South America 9000 oz. of morphine and 700 oz. of heroin; Australasia 5700 oz. of morphine and 1600 oz. of heroin. The statistics do not distinguish between consignments sent by parcel post and others.

Labour Representation on Asylums Board.

Mr. **SCURR** asked the Minister of Health whether, when he was appointing persons to serve on the Metropolitan Asylums Board, he would consider nominations made by the London Labour Party and the London Trades Council.—Mr. N. **CHAMBERLAIN** replied: Yes, Sir.

Nursing Council Rules.

Major **BARNETT** asked the Minister of Health whether the General Nursing Council for England and Wales had yet submitted for his approval rules providing adequately for the direct representation of registered nurses on the Council, and the prescribed scheme of training required by the Nurses Registration Act, 1919; and, if not, whether he would consider the desirability of appointing a select committee to deal with these matters.—Mr. N. **CHAMBERLAIN** replied: The General Nursing Council have submitted a revised scheme for the election of nurse members and rules governing the training of candidates for admission to the register. In accordance with the promise given by my predecessor I am prepared to recommend the appointment of a select committee to examine the election scheme and to report upon the desirability of making the adoption of the Council's syllabus of training compulsory.

The Blind Persons Act.

Mr. **ROBERT YOUNG** asked the Minister of Health whether all local authorities concerned were giving effect to the provisions of the Blind Persons Act, 1920; and whether he could give the number of blind persons who were unemployed and employed, respectively, and the number of those who were under training and of those who were trained but unemployed.—Mr. N. **CHAMBERLAIN** replied: The answer to the first part of the question is in the affirmative. As regards the second part, the latest figures at present available relate to the year 1923. Of the blind population over school age, 20,759 were then returned as unemployable, 8235 as employed, 1246 as under training, and 880 as trained but unemployed.

Surgical Operations on Young Children.

Colonel **DAY** asked the Minister of Health whether, seeing that Westminster Hospital had provided facilities enabling mothers to be accommodated in the hospital to nurse back to health their babies who had undergone serious surgical operations, and that many similar operations were performed in different parts of the country at institutions governed by the local boards of guardians, he was prepared to recommend to local unions the advisability of making provision for such cases, in order that every endeavour should be made to save the lives of such babies.—Mr. N. **CHAMBERLAIN** replied: I am not aware of the nature of the arrangements to which the hon. Member refers, but I am making inquiries in the matter and will communicate with him further.

Pollution of Underground Water.

Lieut.-Colonel **FREMANTLE** asked the Minister of Health whether, when, and in what form, it was proposed to introduce legislation for safeguarding supplies and preventing pollution of underground water, as proposed in the report of the Advisory Committee on Water, recently issued by the Ministry of Health; and what steps would meanwhile be taken to consult the interests affected.—Mr. N. **CHAMBERLAIN** replied: I anticipate that the views of the interests affected by the report will be forthcoming at an early date as the result of the publication of the report. Before considering legislation I must, of course, consider those views, and I may add that there are some other matters relating to water-supplies on which legislation may be required and which the Advisory Committee is now proceeding to consider.

Trevethin Committee and Venereal Disease.

Mr. **PETO** asked the Minister of Health whether the report of the committee presided over by Lord Trevethin was accepted in principle by the Ministry of Health; and whether it was proposed to take any action to carry out the recommendations of the committee.—Mr. N. **CHAMBERLAIN** replied: The principal recommendations in the report of this committee have been accepted by my department, and action is being taken to give effect to them. As regards the recommendation in paragraph 14 of the report, I may say that I am still in correspondence on this matter with the two societies interested in the combating and prevention of venereal disease.

Health Insurance Surplus.

Mr. **BENNETT** asked the Minister of Health whether his attention had been called to the fact that the next valuation of the approved societies would show an available surplus for distribution of benefits of between £15,000,000 and £20,000,000; and whether he would consider the existence of such a surplus from the point of view of whether the weekly contributions need be on the present large scale, and from that of the possibilities of pooling health insurance with the other social insurance schemes of the Government respectively.—Mr. N. **CHAMBERLAIN** replied: I am aware that it has been estimated that the surpluses available for distribution as a result of the second valuation of the approved societies and branches may amount in the aggregate to the figures stated. As regards the second part of the question, the Royal Commission on National Health Insurance have now under review the whole financial structure of the scheme, and I propose to await their findings.

Infantile Mortality in Market Drayton.

Sir **CHARLES OMAN** asked the Minister of Health whether he had published the report as to high infantile mortality in Market Drayton by the medical woman whom last autumn he sent to inspect and report; whether he was aware that the figures for 1924 showed that the infantile mortality for Market Drayton was far more than twice as high as that for Newport and three times as high as that for Wellington; and, if he had not published it, would he do so at once.—Mr. N. **CHAMBERLAIN** replied: The answer to the first question is in the negative. The answer to the second is in the affirmative. I understand that the county council are taking steps to carry out the suggestions which I made to them as a result of the report of my medical officer. Accordingly I do not think the third part of the question arises.

Tuberculosis Care Committees' Finances.

Sir **JOHN LEIGH** asked the Minister of Health whether he was aware that a large balance of unexpended contributions had accumulated in the hands of tuberculosis care committees; what was the total for England and Wales; and how these sums would be utilised.—Mr. N. **CHAMBERLAIN** replied: The answer to the first part of the question is in the negative. The income of tuberculosis care committees is largely derived from voluntary sources, and I have no control over the funds of these committees. So far as I am aware it is exceptional to find that the income of such committees is in excess of their needs.

Vaccination and Small-pox.

Dr. WATTS asked the Minister of Health if he would furnish figures showing the number of children born, the number vaccinated, the number in respect of whom certificates of conscientious objection had been furnished by the parents during the four years ending Dec. 31st, 1924, and also the number of prosecutions which had been taken in respect of those who had neither been vaccinated or whose parents had not obtained certificates of conscientious objection; and would he take steps to ensure that the Vaccination Acts were properly administered.—Mr. N. CHAMBERLAIN replied: I am not yet able to give the information asked for in the first part of the question for the years 1923 and 1924. For 1921 and 1922 the figures are as follows:—

Year.	No. of births.	No. of children vaccinated.	No. of children in respect of whom certificates of conscientious objection were received.
1921	849,060	324,864	382,157
1922	780,277	314,550	347,511

I have no information as to the number of cases in which proceedings have been taken for the enforcement of the provisions of the Vaccination Acts during the years in question. As regards the last part of the question, the administration of the Vaccination Acts is in the hands of the boards of guardians and their vaccination officers.

Lieut.-Colonel FREMANTLE asked the Minister of Health the number of cases and deaths from small-pox for the first four months of this and the previous three years; the percentage of infant vaccinations to births in the last recorded period and in the previous corresponding periods since 1897; and whether he proposed to rely on present methods of sanitary administration and of vaccination administration to check the further spread of the disease or to promote, and, if so, in what way, a fuller recourse to protection by vaccination.—Mr. N. CHAMBERLAIN replied: The following are the figures asked for in the first part of the question:—

Period.	No. of cases of small-pox.	No. of deaths.
First 4 months of—		
1922	317	1
1923	692	—
1924	1569	3
1925	2214*	3

* Provisional figure.

The latest year for which the percentage of infant vaccination to births can at present be given is 1922. The figures for that and previous years were given in my reply to a question on this subject on April 9th. As regards the last part of the question, I am carefully watching the course of the present outbreak of small-pox, but as at present advised I do not consider it at this time necessary or expedient to modify the existing administrative arrangements for dealing with small-pox.

FRIDAY, MAY 8TH.

Blind Persons Bill.

Mr. R. YOUNG, in moving the second reading of the Blind Persons Bill, said that although there was only a comparatively small number of blind persons in the country they were sufficiently numerous to make it incumbent on the House to take action to place on the community the responsibity of providing sustenance for those who were incapable of looking after themselves, training for those who were capable of being trained, work for those who had been trained, and sustenance for those who by reason of their disability had grown prematurely old. He would not attempt to belittle the work which had been done by voluntary organisations such as St. Dunstan's, but that work demonstrated the clamant need of tackling the problem by municipal and national organisation and assistance. The Blind Persons Act of 1920 did not go far enough, and the present Bill, which was a non-party measure, provided that any blind person of 16 years of age and upwards unable to obtain employment in any workshop or place provided and maintained by the local authority in whose area he resided should receive 25*s.* per week so long as he was unemployed. County councils and councils of county boroughs would be responsible for providing workshops and institutions for the blind. There were at present 3000 blind persons in the workhouses, and these should be removed as soon as possible.

Captain FRASER, who is himself blind, opposed the measure on the ground that it proposed to municipalise all the enterprises and institutions which cared for the blind. But having regard to the general desire in all parts of the House to do something for the blind he asked the Minister of Health to set up a select committee to examine what had been done under the Blind Persons Act, 1920, and to see whether local authorities had done their best or not for blind persons.

Sir KINGSLEY WOOD (Parliamentary Secretary to the Ministry of Health) said that the Government shared in the general desire to do everything possible to make the lot of blind people better and happier, and he agreed that it ought to be regarded as a non-party matter. The cost to the Exchequer under the existing Act was £467,000 a year, and it was estimated that the present Bill if passed would mean additional commitments by the local authorities of £1,400,000 per annum. He understood that no local authorities had been consulted with regard to the Bill. The proposal that blind persons unable to obtain employment should receive 25*s.* a week was condemned by the advisory committee for the Welfare of the Blind on the ground that it would tend to mitigate individual effort on the part of blind persons. He thought good service was being done by the Ministry of Health in dealing with another side of the problem—the diminution of persons born blind, or who became blind up to the age of 5. The Government could not recommend the House to pass the second reading of the Bill.

Mr. RAINE, who had a motion on the paper for the rejection of the Bill, was speaking at 4 o'clock, when under the rules of the House the debate stood adjourned. The measure was accordingly "talked out."

MONDAY, MAY 11TH.

Education of Tuberculous Children.

Mr. GROVES asked the President of the Board of Education if he had any information respecting the number of children throughout the country suffering from tuberculosis for whom no educational provision was being made; and what steps he proposed to take in the matter.—Lord E. PERCY replied: According to the returns of local authorities for the year ended Dec. 31st last there were, in England and Wales, 8834 children suffering from some form of tuberculosis, who were attending no recognised school or institution. Probably some of these children could suitably be sent to open-air schools by local authorities, and I am doing all I can to encourage the development of this type of school; but the majority are not physically fit to receive formal instruction in school, and, therefore, fall outside the scope of my department.

Pensions Scheme and Health Insurance.

Sir WALTER DE FRECE asked the Minister of Health whether, in connexion with the new insurance scheme of the Government, it was proposed to pool, either eventually or immediately, on an actuarial basis, the contributions to the Health Insurance Fund and those for the new widows and old age pensions schemes.—Sir KINGSLEY WOOD (Parliamentary Secretary to the Ministry of Health) replied: No, Sir. The Bill provides that the part of the weekly contribution which is assigned to the scheme of contributory pensions is to be paid into a pensions account which will be kept entirely separate from the funds relating to national health insurance.

TUESDAY, MAY 12TH.

Birth-rate and Infantile Mortality in Large Towns.

Mr. GROVES asked the Minister of Health if he had any information showing that the large industrial towns with the greatest degree of unemployment showed the highest birth-rates, the greatest degree of overcrowding, and the highest mortality among infants; and what steps he proposed to effect alteration.—Sir KINGSLEY WOOD replied: The figures for certain districts with the highest average degree of unemployment for the 12 months ended February last indicate that in the majority of these districts the birth-rate and the infant mortality-rate for the year 1924, and the percentage of population living more than two persons to a room, according to the census returns for 1921, were above the average for England. There is not, however, sufficient correspondence between the figures to warrant any general conclusion. The Government are exploring all possible means of reducing unemployment, overcrowding, and infant mortality.

Deaths from Small-pox and other Diseases.

Colonel DAY asked the Minister of Health how many deaths had been registered during the half-year ending December last from small-pox, measles, pneumonia, scarlet fever, diphtheria, and influenza.—Sir KINGSLEY WOOD replied: For England and Wales the figures asked for are as follows: Small-pox, 3*; measles, 1317; pneumonia, 12,381; scarlet fever, 426; diphtheria, 1205; influenza, 2145.

---

* In two of these cases small-pox was entered by the medical practitioner as a contributory cause of death.

Medical News.

UNIVERSITY OF OXFORD: *Fellowship in Physiology at New College.*—The College proposes to elect, not later than October next, to a Fellowship in Physiology. The person elected will be required to undertake, as from Michaelmas term next, the teaching of members of the College reading for the Honour School of Physiology and the medical examinations. Details of the appointment and forms of application can be obtained from the Warden. These forms, duly completed, should be returned to the warden not later than June 15th.

UNIVERSITY OF CAMBRIDGE.—An examination for Part II. of the Cambridge Diploma in Psychological Medicine will be held in London on June 10th, 11th, and 12th. Applications should be made at once to the Registrar, Cambridge University.

UNIVERSITY OF LONDON.—At the election of members to the Senate of the University, which took place on Tuesday, May 12th, Dr. Graham Little, M.P., polled 827 votes, against 281 for Mr. T. B. Layton, in the Faculty of Medicine.

LONDON HOSPITAL MEDICAL COLLEGE (UNIVERSITY OF LONDON).—On Tuesday, June 2nd, the distribution of prizes to successful students will be made by Dr. Charles Mayo, of Rochester, Minnesota, U.S.A., in the library of the College at Turner-street, Mile End, E., at 3 P.M. The distribution will be followed by a garden party.

KING'S COLLEGE HOSPITAL, LONDON.—Upon the recommendation of the medical board, the committee of management have created a new post of psycho-therapist on the honorary staff, and Dr. William Brown, Wilde Reader in Mental Philosophy in the University of Oxford, has been appointed to fill the position.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH, ROYAL COLLEGE OF SURGEONS OF EDINBURGH, AND ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—The following candidates having passed the requisite examinations have been admitted Diplomates in Public Health:—

David G. Anderson, Malcolm J. Bett, Angus H. Campbell, Agnes F. Dickson, William Fraser, Clara F. Gertzen, Jean M. Gilchrist, Mary M. Jack, James C. Lindsay, Peter L. McKinlay, Elizabeth P. Y. Paterson, George H. Percival, William C. Sharp, Annie V. Taylor, John Walker, Elizabeth Wheatley, Alexander B. Williamson, and Anne C. Wilson.

The following candidates passed Part I.: Ruth M. Allinson, Mary V. F. Beattie, Elizabeth S. Cook, Elsie B. Dickinson, Jane T. Gilmour, Hilda R. Hay, Reuben Levinson, William R. Logan, Elizabeth M. Mackay, Richard Norton, Margaret M. Paterson, Joseph Sachs, Donald A. M. Shearer, Malcolm Somerville, Jeanie M. Strathie, and Hector W. Sutherland.

The following candidate passed Part II.: George A. Pollock.

REBUILDING OF MIDDLESEX HOSPITAL.—In an illustrated article dealing with the present state of Middlesex Hospital we referred last week to a meeting of the Court of Governors which it was proposed to hold on May 11th to discuss the whole question of rebuilding. The meeting was held under the presidency of Prince Arthur of Connaught, and the decision of the hospital board was endorsed to rebuild the hospital and launch an immediate appeal for £500,000. It is satisfactory to note that already a preliminary list of donations totalling nearly £40,000 have been subscribed. The sum of £10,000 has been promised from the King Edward Hospital Fund, £10,000 from the trustees of the Ludlow Estate, £5000 from Mr. Vaughan-Morgan, £2500 from Mr. Ernest Debenham, £1000 from Mr. Collins, and a subscription of £2000 from Lord Rothermere and the *Daily Mail.* Messrs. W. and A. Gilbey have also given 1000 guineas. Some £30 had been sent in from former patients in shillings and half-crowns, while the nurses have promised £500. During the rebuilding of the institution the old infirmary buildings in Cleveland-street will be utilised and, given adequate public support, the work of the hospital will be carried on without curtailment. Among those who addressed the meeting were the Duke of Northumberland, Lord Cheylesmore, Lord Bearsted, Sir Arthur Stanley, Mr. T. P. O'Connor, M.P., Mr. Comyns Berkeley, Major Astor, M.P., and Sir John Bland-Sutton, President of the Royal College of Surgeons, who said that though in the new building it might not be possible to incorporate much of the old hospital, it would be possible to incorporate the wonderful spirit of the old founders and emulate the sympathy for the sick and suffering, which was the dominant feature of the men and women whose humanity led them to build the hospital. The President of the appeal committee is Lord Mildmay of Flete.

ABERDEEN UNIVERSITY CLUB, LONDON.—The bi-annual dinner of this club will be held at Gatti's Restaurant, Strand, London, on Thursday, May 21st, at 7.30 P.M., Sir Arthur Greer in the chair. Dr. W. A. Milligan, 11, Upper Brook-street, W. 1, the hon. secretary, will be pleased to hear from either men or women graduates wishing to join the club or attend the dinner.

ROYAL STATISTICAL SOCIETY.—A meeting of this society will be held on May 19th, at 5.15 P.M., in the hall of the Royal Society of Arts, John-street, Adelphi, London, W.C., when Sir Napier Shaw will read a paper on the Week or Month as an Intermediate Time-unit for Statistical Purposes.

LONDON HOSPITAL: NEW CLINICAL THEATRE.—Lord Bearsted recently laid the foundation-stone of a new clinical theatre with which he is presenting the hospital. He is providing £10,000, and whatever is left of that sum after the building is paid for is to be used in endowing a lectureship in connexion with it.

A CHURCH FOR THE DEAF AND DUMB.—St. Saviour's Church and Institute for the Deaf and Dumb in Oxford-street, London, has had to be pulled down owing to the expansion of the shopping area. Its place has been taken by a new church and institute at Acton, which was last week opened by Princess Mary.

LONDON JEWISH HOSPITAL.—Mr. Bernhard Baron has given £10,000 for the completion of the front block of this hospital on the understanding that the balance of the £25,000 required will be raised. Lord Rothschild, the President, announces that the work will therefore proceed immediately.

ROYAL MICROSCOPICAL SOCIETY.—A meeting of this Society will be held in the lecture hall, 20, Hanover-square, London, W., on Wednesday, May 20th. At 8 P.M. the following papers will be read and discussed: Prof. Robert Chambers (Cornell University Medical College): The Technique of Micro-dissection and Injection of Cells. Mr. F. I. G. Rawlins: A Note on the Use of the Neon Lamp in Microscopy (with demonstration by Mr. J. E. Barnard, F.R.S.). Dr. R. J. Ludford, Ph.D. (Institute of Anatomy, University College): The Cytology of Cancer.

ROYAL EAST SUSSEX HOSPITAL.—Although the income exceeded the expenditure by £2199 at this Hastings institution, it was explained at the eighty-fifth annual meeting, held on May 7th, that this was due to the wonderful and generous response from the public—something like £7000 being raised by way of extraordinary support—and not, as was hoped, an increase in the number of annual subscribers. Special appeals could not continually be made; annual subscribers were the backbone of the financial support of every hospital. The year's work of the institution showed an increase in all departments.

AMERICAN HOSPITAL COSTS.—The sixtieth annual report of the Boston City Hospital shows that the daily cost of each in-patient is 13*s.* 4*d.*; at the convalescent home it is about 10*s.* 6*d.* Out-patients cost 2*s.* per visit. The gynæcological and obstetrical work is increasing with such rapidity that it is difficult to cope with it—"serious results seem almost certain to occur" unless greater facilities are provided. Most of the great American hospitals are, indeed, faced with similar difficulties in consequence of the growing popularity of antenatal clinics and the resulting increase in the number of maternity patients.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—Dr. T. W. Eden will deliver a lecture on the Prevention of Puerperal Sepsis in the West Lecture Hall at 1, Wimpole-street, on Monday, May 18th, at 5.30 P.M. On the same date will begin the two weeks' course arranged for the convenience of general practitioners at the London Temperance Hospital from 4.30 P.M. A special course in Diseases of Infants will be held at the Infants Hospital from May 18th to 30th. A two weeks' afternoon course in Dermatology has been arranged from May 18th to the end of the month by the Hospital for Diseases of the Skin (Blackfriars), affording an opportunity for study in the out-patient department and venereal clinics. A special demonstration of cases will take place on May 19th. During June there will be the following courses: Diseases of the Chest, at the Victoria Park Hospital for Diseases of the Heart and Lungs; Gynæcology, at the Chelsea Hospital for Women; Tropical Medicine, at the London School of Hygiene and Tropical Medicine; Urology, at St. Peter's Hospital; Venereal Diseases, at the London Lock Hospital; and an intensive course in general medicine, surgery, and the specialties at the London Temperance Hospital. Copies of each syllabus may be obtained on application to the Secretary to the Fellowship, 1, Wimpole-street, London, W. 1, from whom also a copy of the programme of work may be had.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MEETINGS OF SECTIONS.

Tuesday, May 19th.

GENERAL MEETING OF FELLOWS: at 5.30 P.M.
Ballot for election to the Fellowship.

Wednesday, May 20th.

HISTORY OF MEDICINE: at 5 P.M.
Annual General Meeting:
Election of Officers and Council for 1925–1926.
Paper:
Mr. W. H. S. Jones: The Historical Value of the Hippocratic Collection.
Exhibit:
Mr. C. E. Wallis: Eighteenth Century Apothecaries' Indentures.

Thursday, May 21st.

DERMATOLOGY: at 5 P.M. (Cases at 4 P.M.)
Annual General Meeting:
Election of Officers and Council for 1925–1926.
Nomination of Corresponding Members.
Cases:
The following will be shown by:—
Dr. H. W. Barber: (Private case) Lichen Nitidus with Lesions on Hard Palate.
Dr. H. MacCormac: (Private case) Leprosy.
Dr. H. C. Semon: Acne Varioliformis.
Dr. J. M. H. MacLeod: Sarcoid.
Dr. G. B. Dowling: Sections of Urticaria Pigmentosa.
Paper:
Prof. Bosellini (Bologna).
The Annual Dinner, at which Prof. Bosellini will be the guest of the Section, will take place at Oddenino's Restaurant, Regent-street, W., on the same evening, at 7.15 for 7.30 P.M. Price 12*s.* 6*d.*, exclusive of wine, payable at the table.

Friday, May 22nd.

STUDY OF DISEASE IN CHILDREN: at 5 P.M. (Cases at 4.30 P.M.)
Annual General Meeting:
Election of Officers and Council for 1925–1926.
Cases will be shown.

Saturday, May 23rd.

BALNEOLOGY AND CLIMATOLOGY:
Annual Provincial Meeting in Brighton:
The Annual General Meeting will be held, by kind permission of the Mayor and Corporation, in the Pavilion, at 3.30 in the afternoon, for the election of Officers and Council.
Dr. Duncan Forbes, M.O.H. Brighton, will read a paper on the Climate of Brighton.
Fellows, Members, and their wives will be received at 4.30 P.M. at the Pavilion by His Worship the Mayor of Brighton, who will kindly provide tea.
The Director of the Pavilion, Mr. Henry D. Roberts, will give a short address on its history, and conduct the party over the building.
The Annual Banquet will take place at the Hotel Metropole.

ROYAL INSTITUTION, 21, Albemarle-street, W.
Tuesday, May 19th.—5.15 P.M., Prof. R. Whiddington: Passage of Electricity Through Vacuum Tubes (I.).
Friday.—9 P.M., Dr. Thorne M. Carpenter: Metabolism of Man and Animals.

MEDICO-LEGAL SOCIETY, 11, Chandos-street, Cavendish-square, W.
Tuesday, May 19th.—8.30 P.M., Dr. L. A. Weatherly: Medical Aspects of Some Murder Cases in which Insanity was the Defence. To be followed by a Discussion.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE, 11, Chandos-street, Cavendish-square, W.
Thursday, May 21st.—7.45 P.M., Demonstration by Lieut.-Colonel J. Cunningham, I.M.S. 8.15 P.M., Paper on Serological Observations on Relapsing Fever in Madras.

TUBERCULOSIS SOCIETY.
Friday, May 22nd.—8 P.M. (at the House of the Society of Medical Officers of Health, Upper Montague-street, Russell-square), Dr. R. Gloyne: Pulmonary Conditions Simulating Tuberculosis.

LONDON DERMATOLOGICAL SOCIETY, St. John's Hospital, 49, Leicester-square, W.C.
Wednesday, May 20th.—4.30 P.M., Clinical Cases and Specimens. 5.15 P.M., Dr. Prosser White: Cutaneous Sensitisation in Industrial Dermatoses.
The monthly dinner will be held at the Cavour Restaurant, Leicester-square, in a private room at 6.30 P.M. Will Fellows intending to be present kindly inform the Hon. Secretary before the meeting?

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.
Monday, May 18th, to Saturday, May 23rd.—West Lecture Hall, Royal Society of Medicine. Lecture arranged by the Fellowship of Medicine and open to all members of the medical profession. At 5.30 P.M., Dr. T. W. Eden: The Prevention of Puerperal Sepsis.—London Temperance Hospital, Hampstead-road, N.W. Special Post-Graduate Course for Practitioners. Daily at 4.30 P.M. Clinical demonstration for one hour, followed by a lecture for half an hour. General medicine, surgery, and special departments.—Infants Hospital, Vincent-square, S.W. Special Course in Diseases of Infants. Lectures and demonstrations every afternoon. "Round-table" Conference on Friday, and special visits on Saturday afternoon and Sunday morning.—Hospital for Diseases of the Skin, Blackfriars, S.E. Post-graduate Course in Dermatology, consisting of instruction in the out-patient department every afternoon, and a Venereal Clinic on Tuesday and Friday. Special demonstration of interesting cases on Tuesday, May 19th.—Central London Throat, Nose, and Ear Hospital, Gray's Inn-road, W.C. Special Course in Laryngology, Rhinology, and Otology. Daily operations, lectures, and clinics. Morning and afternoon sessions. Operative surgery class every morning. Clinical and Operative courses may be taken separately, or combined.—Maudsley Hospital, Denmark-hill, S.E. Course in Psychological Medicine. Lectures on the Psychoneuroses, the Practical Aspect of Mental Deficiency, the Pathology of Mental Diseases; and Demonstrations in Clinical Psychiatry and Clinical Neurology.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C. 1.

POST-GRADUATE COURSE: May–June, 1925.

Clinical Lectures and Demonstrations.

Monday, May 18th.—2 P.M., Out-patient Clinic: Dr. Hinds Howell. 3.30 P.M., Syphilis of Nervous System: Dr. Adie.
Tuesday, May 19th.—2 P.M., Out-patient Clinic: Dr. Walshe. 3.30 P.M., Peripheral Neuritis: Dr. Birley.
Thursday, May 21st.—2 P.M., Out-patient Clinic: Dr. Kinnier Wilson. 3.30 P.M., Encephalitis Lethargica and its Sequelæ: Dr. Hinds Howell.
Friday, May 22nd.—2 P.M., Out-patient Clinic: Dr. Gordon Holmes. 3.30 P.M., Auditory Nerve Tumours: Mr. Sydney Scott.

Course of Lectures and Demonstrations on the Pathology of the Nervous System.

Monday, May 18th.—12 noon, The Cerebro-Spinal Fluid. Physiology and Pathology: Dr. J. G. Greenfield.

Course of Lectures and Demonstrations on the Anatomy and Physiology of the Nervous System.

Tuesday, May 19th.—12 noon. Structure of Spinal Cord, Brain-stem, and Cerebellum.
Thursday, May 21st.—12 noon, The Physiology of the Motor System: Dr. Walshe.
Dr. H. J. Macbride will give a Course of Eight Clinical Demonstrations, chiefly on Methods of Examination of the Nervous System, in the Wards at 10 A.M. on Tuesdays and Fridays, if sufficient entries are received. The fee for this Course will be £2 2*s.* (commencing Tuesday, May 19th).
Mr. Armour and Mr. Sargent operate at the Hospital on Tuesday and Friday mornings at 9 A.M., or at such other times as may be announced.
Any part of the Course may be taken separately. Special arrangements will be made for those unable to take the whole Course.
Fees should be paid to the Secretary of the Hospital at the Office on entering for the Course.
J. G. Greenfield, Dean of Medical School.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.
Monday, May 18th.—12 noon, Mr. Simmonds: Applied Anatomy. 2 P.M., Dr. Scott Pinchin: Medical Out-patients. 2 P.M., Mr. Bishop Harman: Eye Dept.
Tuesday.—10 A.M., Medical Registrar: Clinical Methods. 12 noon, Dr. Burrell: Chest Cases. 2.30 P.M., Mr. Tyrrell Gray: Surgical Wards.
Wednesday.—2 P.M., Dr. Burnford: Medical Wards. 2 P.M., Dr. Owen: Medical Out-patients. 2.30 P.M., Mr. Donald Armour: Surgical Wards.
Thursday.—10 A.M., Dr. Grainger Stewart: Neurological Dept. 11 A.M., Sir Henry Simson: Gynæcological Wards. 2 P.M., Mr. MacDonald: Genito-Urinary Dept.
Friday.—12 noon, Surgical Registrar: Surgical Pathology. 2 P.M., Mr. Sinclair: Surgical Out-patients. 3 P.M., Dr. Pritchard: Medical Wards.
Saturday.—10 A.M., Dr. Saunders: Medical Diseases of Children. 10 A.M., Mr. Banks-Davis: Operations on Throat, Nose, and Ear.
Daily, 10 A.M. to 6 P.M., Saturdays, 10 A.M. to 1 P.M., In-patients, Out-patients, Operations, Special Departments.

UNIVERSITY COLLEGE, Gower-street, W.C.
Friday, May 22nd.—5.30 P.M., Prof. G. Elliot Smith, F.R.S.: The Taungs Skull—Missing Links.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

Tuesday, May 19th.—4.30 p.m., Opening Lectures of Summer Session, Mr. H. W. Carson: The Diagnosis and Prognosis of Cancer of the Rectum.

Friday.—4.30 p.m., Mr. J. Howell Evans: Hydrocele, Hæmatocele, and Pyocele.

Daily.—Clinics in General and Special Departments, Demonstrations, Operations, &c.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, Leicester-square, W.

Tuesday, May 19th.—5 p.m., Dr. MacCormac: Acne Vulgaris.

Thursday.—5 p.m., Dr. Griffith: Skin Eruptions of Syphilis.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.

Thursday, May 21st.—4 p.m., Dr. T. Thompson: Mental Deficiency in Children.

ST. MARY'S HOSPITAL INSTITUTE OF PATHOLOGY.

Thursday, May 21st.—5 p.m., Prof. E. W. Macbride: The Inheritance of Acquired Qualities.

UNIVERSITY OF LIVERPOOL POST-GRADUATE LECTURES. (At 3.30 p.m.)

Monday, May 18th.—(At the Shaw-street Hospital.) Mr. Leyland Robinson: Treatment of Fibroids.

Tuesday.—(At the Maternity Hospital.) Dr. J. W. Burns: Placenta Prævia and Accidental Hæmorrhage.

Wednesday.—(At the St. Paul's Eye Hospital.) Mr. Haward Bywater: Clinical Cases.

Thursday.—(At the St. George's Skin Hospital.) Dr. F. H. Barendt: Skin Cases.

MANCHESTER ROYAL INFIRMARY.

Tuesday, May 19th.—4.15 p.m., Mr. J. P. Buckley: Practical Points in Relation to Hernia.

Friday.—4.15 p.m., Miss Peile: Massage Demonstration. Mr. J. P. Buckley: Surgical Demonstration.

UNIVERSITY OF SHEFFIELD FACULTY OF MEDICINE.

Tuesday, May 19th.—8.45 p.m. (in the Medical Library), Prof. Dr. B. Brouwer (University of Amsterdam): The Projection of the Retina in the Brain (in English).

Appointments.

Jacob, F. H., M.D. Lond., has been appointed one of the Medical Referees under the Workmen's Compensation Act for the Districts of the Newark and Nottingham County Courts.

Phillips, P., M.B., Ch.B. Bristol, Medical Superintendent of the Southmead Hospital.

Raines, R., M.R.C.S., L.R.C.P. Lond., D.P.H., Deputy Assistant Medical Officer of Health, Hull and Goole Port Sanitary Authority.

Cardiff Health and Education Authority: Betenson, W. F. W., M.B., Ch.B. Aberd., D.P.H., and Roberts, T. E., M.B., B.S. Lond., D.P.H. Camb., School Medical Officers.

King's College Hospital: Playfair, H. J. M., M.D. Lond., F.R.C.P. Lond., Consulting Obstetric and Gynæcological Surgeon and Emeritus Lecturer on Obstetric and Gynæcological Surgery; Gilliatt, W., M.D., M.S. Lond., F.R.C.S. Eng., Obstetric and Gynæcological Surgeon; Palmer, A. C., M.B., B.S. Lond., F.R.C.S. Eng., Junior Obstetric and Gynæcological Surgeon; and Wiltshire, H. W., M.D. Camb., F.R.C.P. Lond., Consulting Physician.

New Sussex Hospital for Women and Children, Brighton: Wauchope, G. M., M.B., B.S. Lond., Honorary Assistant Physician; Rickards, E., M.B., M.S. Lond., F.R.C.S. Eng., Temporary Assistant Surgeon; Logan, B. M., M.B., Ch.B. Aberd., Assistant Anæsthetist.

Vacancies.

For further information refer to the advertisement columns.

Brighton, Hove Hospital.—R.M.O. £175.
Brighton, Royal Sussex County Hospital.—H.P. £150.
Cambridge, Papworth Hall.—Asst. M.O. £300.
Cancer Hospital, Fulham-road, S.W.—H.S. at rate of £100.
Carshalton, Surrey, Queen Mary's Hospital for Children.—Jun. Asst. M.O. £500.
Cassel Hospital for Functional Nervous Disorders, Swaylands, Penshurst, Kent.—R.M.O. £400.
Central London Ophthalmic Hospital, Judd-street, W.C.—Pathologist. £75.
Charing Cross Hospital, W.C.—Res. Anæsthetist at rate of £100.
Chelsea Hospital for Women, Arthur-street, S.W.—Sen. and Jun. H.S.'s at rate of £120 and £100 per annum respectively.
Chester Royal Infirmary.—Hon. Surg.
Doncaster Royal Infirmary.—Asst. H.S. £150.
Dreadnought Hospital, Greenwich.—Anæsthetist. 50 guineas.
East Lancashire Tuberculosis Colony and Sanatorium, Barrowmore Hall, Great Barrow, near Chester.—Asst. M.O. £250.
East London Hospital for Children, &c.—Morning Cas. O. at rate of £120. Also Anæsthetist. £50.
Essex, Administrative County of.—Asst. Tuberculosis O. £600.
Elizabeth Garrett Anderson Hospital, Euston-road, N.W.—H.P., Obstet. Asst., and two H.S.'s. Each at rate of £50.
Evelina Hospital for Children, Southwark, S.E.—H.P. £120. Also Hon. H.P. to Out-patients.
Gloucestershire Royal Infirmary and Eye Institution.—Asst. S.
Huddersfield Royal Infirmary.—Jun. H.S. £150.
Lanark County.—Bacteriologist and Pathologist. £750.
London Temperance Hospital, Hampstead-road, N.W.—Res. M.O. at rate of £175.
Maidstone, Kent County Ophthalmic Hospital.—H.S. £300.
Manchester City.—Female M.O. £632 7s. 8d.
Manchester, East Lancashire Homes for Disabled Sailors and Soldiers, Broughton House, Park-lane, Kersal.—Res. Med. Supt. £400.
Metropolitan Hospital, Kingsland-road, E.—Asst. P.
Middlesex County Council.—Deputy County M.O.H. at rate of £900.
Mildmay Mission Hospital, Austin-street, Bethnal Green, E.—Sen. Res. M.O. £140. Also Jun. Res. M.O. £100.
Miller General Hospital for South-East London, Greenwich-road, S.E.—Res. Cas. O. £150.
Monmouthshire County Council.—Asst. M.O. £500.
Newcastle-upon-Tyne, Royal Victoria Infirmary.—Hon. S.
Nuneaton, Caldecote Hall, Home for Male Inebriates.—Res. Med. Supt. £400.
Oxford, Radcliffe Infirmary and County Hospital.—H.S. and Cas. H.S. Each at rate of £120.
Paddington Metropolitan Borough.—M.O.H. £1000.
Patna, India, Medical College.—Prof. of Pharmacology, Prof. of Anatomy, and Prof. of Physiology. Each Rs.1200 per mensem.
Portsmouth, Royal Portsmouth Hospital.—Cas. O. at rate of £100.
Radcliffe-on-Trent, Notts County Mental Hospital.—Jun. Asst. M.O. £300.
Royal College of Surgeons of England.—Election to Court of Examiners. Also Professors and Lecturers.
Royal Dental Hospital of London, Leicester-square, W.C.—Two Hon. Asst. Dent. S.'s.
Royal Northern Hospital, Holloway, N.—Obstet. S.
Royal Waterloo Hospital for Children and Women, Waterloo-road, S.E.—Cas. O. £150. H.S. and H.P. Each at rate of £100. Also Hon. P. and Asst. in X Ray Dept.
St. Bartholomew's Hospital, Special Treatment Centre, Golden-lane.—Clin. Asstships.
St. Mary Abbots Hospital, Marloes-road, Kensington.—Fourth Asst. M.O. £335 6s.
Salford Union Infirmary, Hope, Pendleton, near Manchester.—Asst. Res. M.O. at rate of £275.
Shrewsbury Borough.—M.O.H., &c. £800.
Stoke-on-Trent, Bucknall Infectious Diseases Hospital.—Asst. M.O. £200.
Truro, Royal Cornwall Infirmary.—H.S. £170.
Victoria Hospital for Children, Tite-street, Chelsea, S.W.—Hon. P. to Out-patients.
Wigan Infirmary.—Third H.S. at rate of £150.
Wolverhampton and Staffordshire Hospital.—R.M.O. at rate of £150.

The Chief Inspector of Factories, Home Office, London, S.W., announces vacant appointments at Borrowash, Derby; and Yaxley, Hunts.

Births, Marriages, and Deaths.

BIRTHS.

Horgan.—On May 4th, at Rua do Sacramento á Lapa 25, Lisbon, the wife of Dr. D. St. Helier Horgan, of a son.

Mills.—On May 2nd, at Lancaster House, Southwold, Suffolk, the wife of Major P. S. Mills, I.M.S., of a daughter (Anne).

MARRIAGES.

Crookshank—Bonhoure.—On May 9th, in London, F. G. Crookshank, M.D., F.R.C.P., to Hélène, second daughter of the late Prof. Gustave Bonhoure, of Vendôme.

Hutton—Lintott.—On April 30th, at Godalming, Samuel King Hutton, M.B., F.R.G.S., of "Kivalek," Parkstone-road, Poole, to Mary, daughter of Henry Lintott, Esq., of Chiddingfold, Surrey.

Shepherd—Wiseman.—On May 7th, at Aurdal, Norway, Charles Woolley Shepperd, M.B., B.S., of St. Andrew's-crescent, Cardiff, to Aagot "Mosse," youngest daughter of Dr. and Mrs. Wiseman, of Tonsaasen, Norway.

DEATHS.

Duguid.—On May 5th, in a nursing home at Aberdeen, William Robert Duguid, M.B., C.M., aged 56 years.

Hume.—On May 6th, at Fircroft, St. Mary Church, Torquay, Walter Augustus Hume, M.R.C.S., L.S.A., in his 69th year.

Travis.—On May 4th, at the residence of Mr. John Hughes, The Manor House, Hampton, Middlesex, William Owen Travis, M.D., aged 68 years.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

TUBERCULOSIS WORK IN CANADA.

IN an address which he gave recently to the Society of Superintendents of Tuberculosis Institutions, Dr. R. E. Wodehouse, Secretary of the Canadian Tuberculosis Association, showed by statistics the remarkable fall in the death-rate from tuberculosis in Canada since 1901, with more detailed figures showing the same fall in the industrial city of Hamilton, Ontario. In 1901 the death-rate from all forms of tuberculosis in Canada was 180; in 1924 it was 84·7 per 100,000 of the population. Hamilton showed a fall from 121 per 100,000 in 1905 to 43·4 in 1924. In this city the deaths from non-pulmonary tuberculosis averaged 15 per cent. of the total deaths from tuberculosis, and showed practically the same fall in the death-rate as in the case of pulmonary tuberculosis. The death-rate from tuberculosis was falling faster than the death-rate from all causes, the former being approximately 8 per cent. of the latter in 1905 and 5 per cent. in 1924. In Hamilton in 1913 and 1914 there was a backward wave in the tuberculosis death-rate which could not have been a war effect. In the different provinces in Canada the tuberculosis death-rate per 100,000 in 1922 was 132 in Nova Scotia and 121 in Quebec, while only 66 in Ontario, 74 in British Columbia, 60 in Manitoba, 51 in Alberta, and 44 in Saskatchewan. The number of sanatorium beds provided per 100,000 of population was low in Quebec (21), high in Nova Scotia (62), Manitoba (61), and Ontario (68), and intermediate in the other provinces named. This represented on the average 635 beds per 1000 deaths. The chief feature of these statistics was the backwardness of the province of Quebec, with mainly a French population. A large provision of new beds was, however, being made in Quebec. The general hospitals aided by government grants in Alberta, British Columbia, Manitoba, Ontario, and Saskatchewan kept 10 per cent. of their beds for tuberculous patients.

In Canada there were, Dr. Wodehouse said, no tuberculosis officers. The work was done by travelling diagnosticians and by the staffs of sanatoriums to whom the general practitioners sent cases for examination. Children with defective teeth had a 12 per cent. higher incidence of tuberculosis. He outlined the scheme for dealing with tuberculosis in Quebec, which was similar to the Framingham experiment. He emphasised the difficulties of the work among the Indians because of their nomadic instincts. Yet with them wonderful results were obtained despite their lack of rest and terrific output of energy, if only the diet were made abundant. In Canadian sanatoriums the tendency was to rest even afebrile patients for long periods, and graduated labour was not looked upon with favour. The cases were in a more advanced stage than in English sanatoriums. Sanatorium costs were usually from 10*s.* to 12*s.* per patient per day as compared with an average of 6*s.* in England, the greater cost being due to the generally higher standard of wages.

In regard to vocational training, it was pointed out that few who received such training stuck to it permanently, and it was therefore being abandoned as being neither feasible nor wise. New York had similarly given up factories for tuberculous people and had resorted to placing the tuberculous in ordinary industries. There was no real isolation of cases but a distinct policy of getting cases into sanatoriums for prolonged treatment. Compulsion, though provided by the law, was not enforced. Hitherto all effort in Canada had been concentrated on pulmonary tuberculosis, and surgical tuberculosis had been left to the general and children's hospitals to deal with. Sanatoriums were well heated in winter and were mainly built of wood, a material regarded in Canada as "permanent."

In thanking Dr. Wodehouse for his address, Dr. James Watt, President of the Society, said that the Canadian figures showed health activities to be responsible for a falling tuberculosis death-rate. In this country too much stress, he suggested, had been laid on improvement in economic conditions.

RE-EDUCATION IN ALEXIA.

To the Editor of THE LANCET.

SIR,—In the treatment of disorders of speech it is not uncommon to meet with cases of aphasia in which a defect of speech may be found in conjunction with another allied defect. The following case may prove of interest.

A boy, aged 11, a patient at the West London Hospital, was sent to me for treatment. He had had meningitis two years previously, and since then had entirely lost the power to read—a type of aphasia classed as alexia. Before the onset of the illness he had done well at school, and passed the usual standards. At five years old he had been a good reader for his age. At the time that he came to me, in addition to the alexic condition, he stammered badly when excited, but all his other faculties were intact, and his intelligence appeared perfectly normal. He suffered from night-terrors, and was otherwise of a highly-strung, nervous temperament.

The plan on which I proceeded to deal with the condition of alexia was that of establishing a complete mental cycle. I selected several objects in common use, or commonly seen, the names of which consisted of one syllable (later two), and of two, three, or four letters, such as ink, cap, bag, bat, ball, hat, dog. Pointing to one such object I would get him to name it. When he had said the word I made him repeat it carefully, listening to his own pronunciation, and then analyse the sounds of which it consisted, as in the teaching of phonetics. I then got him to name the letter represented by each sound respectively, in order of occurrence, and having done so, to write it down, until the complete word was written. He then had to pronounce the word again while looking at it, first as written down by himself, and immediately afterwards from a blackboard on which I wrote it. Finally, having thus named the written word, he was asked to point out the object which it represented, thus arriving back at the point from which he had started and so completing the circuit. After a few words had been worked through in this way, the first word would be returned to and read from the blackboard without the preliminary process of object-recognition, thus encouraging the establishment of word-memory images, and the words so read on one day would be repeated on the next, while the longer process of linking up associations was gone through with fresh objects—verbs being represented by the appropriate actions.

The plan was successful. After about three weekly visits (the procedure meanwhile being followed up at home) the patient was reading simple sentences with creditable ease, and once the wheel had, so to speak, been set revolving, the power to recognise other words returned.

I am, Sir, yours faithfully,
(Miss) W. MARSHALL WARD,
Instructor for Speech Defects at the West London and
Bethlem Royal Hospitals; Director of the
May 11th, 1925. Western Speech Clinic.

CLEAN MILK IN HOSPITALS.

Dr. Chalmers Watson has been able to obtain simultaneous insertion of his article on Clean Milk in four principal Scottish daily journals. He lays stress on the amazing fact that apparently none of the leading general hospitals or children's hospitals in Scotland have given serious consideration to their milk-supply. This, he thinks, is the more remarkable, inasmuch as two-thirds of disease in children's hospitals arises directly from defective nutrition and very largely from the impurity of the milk-supply. There are, he adds, at the present time, only 12 producers of certified milk in Scotland and 21 producers of Grade A tuberculin tested. Although the number of clean milk producers may be six or seven times as large in England, he has ascertained that practically no hospital, save perhaps local hospitals in the immediate vicinity of a producer's farm, takes certified milk. Several hospitals are making inquiries at the present time as to the use of Grade A tuberculin tested, while St. Bartholomew's Hospital actually uses it. Middlesex Hospital obtains Grade A milk for the maternity and children's ward and for all throat cases, and proposes to extend its use. Certain local authorities also have instructed their milk dealers that, as from July next, their welfare centres must be provided with Grade A T.T. In this connexion the borough of Bermondsey is quoted as taking the lead.

WATER-PIPES AND ELECTRIC CURRENTS.

IN a recent article Dr. J. C. Thresh (THE LANCET, March 28th, p. 676) stated that copper water-pipes should not be used for earthing electric current for fear of setting up electrolytic action, whereby copper would go into solution. A correspondent inquires whether any similar objection applies to attaching the earth-wire of a "wireless" set to a lead pipe or watertank. We are informed that using such pipes for wireless earths cannot possibly affect either the pipes or the water, as any currents that would flow to earth through them besides being infinitesimal in amount are rapidly alternating and so could have no electrolytic action. The situation is entirely different in regard to the earthing of the returning track and conductors of a tramway system where a few hundred ampères of direct current may be flowing about in the earth and be very willing to accept the help of any metallic conductor, such as a pipe, on their way back to the power station. This nuisance has, of course, long ago been dealt with to everyone's satisfaction by the Board of Trade.

MR. GREIFFENHAGEN'S PORTRAIT OF SIR DONALD MACALISTER.

A REFERENCE made last week to the possible destination of Mr. Greiffenhagen's portrait of Sir Donald MacAlister has brought us the information that the picture exhibited at Burlington House is taken from the one presented by Lady MacAlister to the General Medical Council.

An Address

ON THE

SIGNIFICANCE OF OCULAR SYMPTOMS.

Delivered before the Wimbledon Medical Society

By PERCY FLEMMING, F.R.C.S. Eng.,
CONSULTING OPHTHALMIC SURGEON, UNIVERSITY COLLEGE HOSPITAL; CONSULTING SURGEON, MOORFIELDS EYE HOSPITAL.

I have chosen for my subject the significance of ocular symptoms, because, whatever our line of practice may be, it is obvious that our object is to do the best we can to relieve the patient's ailments, and the first step to be taken to attain this end is to find out what the patient is complaining of, in other words, to listen to his symptoms. This is often enough a tedious business, but I am sure it pays in the end to listen. Having heard the patient's symptoms, one should be able in a general way to estimate their significance and then ascertain by physical examination their special significance in this particular case.

Pain.

Naturally the first symptom to deal with is pain. It is, of course, impossible to measure its severity; as good a guide as any is whether it keeps the patient awake at night or not. Pain in connexion with the eye of sufficient severity to prevent sleep, and at the same time associated with redness of the eye, suggests iritis, glaucoma, a foreign body, or abrasion of the cornea. The pain of iritis and glaucoma may be much the same—severe and deep-seated, round the eye, extending into the jaws, and occasionally producing vomiting. In the slighter cases of glaucoma it may be not severe enough to prevent sleep altogether and in such circumstances it usually disappears as a result of the sleep. So much importance is attached, and rightly so, to the fact that the pain of glaucoma usually prevents sleep, that the significance of a pretty severe eye pain which is relieved by sleep may be misunderstood. The condition of the pupil enables a diagnosis to be made between iritis and glaucoma—small in iritis, dilated in glaucoma—and I would point out the advisability of making a record in any given case of the state of the pupil before either eserine or atropine is instilled. It is in such cases as these that a second opinion may be asked for, and the difficulty of diagnosis is much increased if the state of the pupil at the time of the onset of the pain is not known. Pain due to a foreign body or abrasion is intense but spasmodic, coming on with the movement of the eyelids, and therefore, not uncommonly occurring at the moment of waking; a drop of fluorescin followed by cocaine is a most useful method of revealing the presence of an abrasion or foreign body.

If the eyeball is quite normal in appearance and yet is said to be the seat of severe pain, it is possible that the pain may be exaggerated; but it is worth while keeping in mind the possibility of the pain being a prodromal symptom of ophthalmic shingles. A few days will suffice to clear up the diagnosis.

Discomfort about the eye with a feeling of gravel or grit in it, sometimes described as a burning sensation getting worse in artificial light, indicates conjunctivitis, usually of a mild type. One of the commonest errors in my experience is the failure to recognise the condition known as spasmodic entropion. This occurs in elderly patients; the lashes of the lower lids roll in—do not grow in—and keep up a constant irritation of the lower part of the conjunctiva of the globe. The resultant conjunctivitis may be recognised and treated, but the cause is often overlooked.

Pain referred to the back of the eyes coming on *at once* when any close work such as reading or sewing is attempted may be a very troublesome symptom. It naturally suggests an error of refraction, or some want of muscle balance. Frequently in these patients the eyes are normal in all respects, and even if there be a little hypermetropia this would not account for the pain coming on at once and being referred to the back of the eyes. You are probably all familiar with these cases. Life is spoilt by the inability to use the eyes—all kinds of glasses are tried without avail—one person is consulted after the other. What, then, does this symptom indicate? The condition is one of local neurasthenia, an example of anxiety neurosis, and cannot be cured by any deliberate action of the will. The pain and disability persist until the attention becomes focused elsewhere; all the symptoms may vanish if a simple appendix operation be performed or the tonsils be enucleated.

Headache.

Pain naturally leads to the consideration of headache. It is very easy to jump to the conclusion that a headache is due to an error of refraction and to neglect to search for some other possible cause. Before accepting the diagnosis of the ocular origin for a headache two conditions should be fulfilled. In the first place it is not every error of refraction that is likely to cause headache; simple myopia, for example, may cause aching eyes, but not a headache. Hypermetropia and astigmatism, especially of *low* degree, are the particular errors most prone to cause headache.

Secondly, headache of ocular origin should have the following characteristics:—

1. *Age.*—Ocular headaches are common in school life and up to middle age, but it is usually a mistake to attribute headache in a patient over 50 to eye-strain.

2. *Site: Usually Frontal or Supraorbital.*—Many patients quite definitely put their thumb and index finger on the mid-orbital points to indicate the seat of pain. Another common situation is at the back of the neck where it joins the head. On the other hand, headache referred to the vertex should not, I think, be attributed to an error of refraction.

3. *Periodicity.*—It frequently occurs on waking—gets better or even disappears after breakfast, returns as the day draws to a close, especially if the eyes are used for close work, but does not interfere with sleep.

It is perhaps worth while to spend a few minutes in explaining the morning headache of eye-strain, as the fact of waking with a headache after a night's rest is often thought to exclude the eyes as the cause of the headache. Ocular headache is due to excessive accommodation necessitated by the hypermetropic refraction. The accommodation is, of course, relaxed during sleep, but the actual act of waking necessitates an effort of accommodation on some very near object—the bed, the room—and later for shaving or doing the hair: and it is this sudden effort of accommodation that starts the headache. It follows from this that people who suffer in this way should get relief by putting on their glasses the moment they awake, and this is usually found to be the case.

Migraine.—True migraine is preceded by subjective visual sensations, sudden attacks of half-vision—fortification spectra, zig-zags, and so on—which the patient naturally enough attributes to the eyes. Children may be shy of telling their experiences. In some cases the aura is the sole phenomenon, no headache following. The significance of migraine is that although the symptoms are strikingly ocular in character it is the central nervous system which is at fault. It is maintained by some authorities that migraine can be cured by correcting the error of refraction. This is not my experience. Such errors should be corrected, but the treatment should not end there.

Common Subjective Sensations.

I would now draw attention to certain subjective sensations which are common and often give rise to much worry.

Floating Specks.—In the vast majority of cases these muscæ volitantes do not indicate any organic disease, the important point is to find out if the specks seen by the patient stand still or move when steadfastly looked at. The average patient is, of course, not a good observer. He probably replies: "Oh, they move with my eye." Get him to try to look at them. Muscæ always move—will not, as it were, stand being looked at. If there is the slightest doubt as to whether they move or not, a thorough ophthalmoscopic examination with the pupil dilated is necessary to clear up the diagnosis. Some people, usually those who are not very busy, are much worried by these muscæ, simply live round them, draw them at different times of the day, and are extraordinarily difficult to help. I think the first step is to make a thorough ophthalmoscopic examination and if the media are clear to assure them that the symptom is not a serious one, and try to persuade them to give up looking for the specks.

Seeing coloured rings round light—the light, for example, resulting from a struck match is often the occasion of the observation. This may be a trivial symptom or one of grave significance. It may merely indicate a watery eye, or simple conjunctivitis, or be a symptom of glaucoma. The production of the rainbow colours is in the former case due to a drop of water sticking on the cornea, in the latter to fluid imprisoned in the cornea, the result of the increase of tension. Careful examination should make it easy to differentiate between the two conditions. If there be no conjunctival discharge, no watery eye, coloured rings indicate glaucoma. Further examination will reveal increase of tension, haziness of cornea, &c.

Flashes of light—specially obvious in the dark—is not an uncommon symptom and may be due to several causes. In investigating it, first make sure that the patient is not describing the aura of migraine. The cause of the flash is some mechanical stimulation of the retina, so the symptom is always serious. If it occurs in a short-sighted individual, the chances are that a detachment of the retina is imminent, or is actually taking place, and a timely rest may prevent the occurrence of the detachment, and similarly the persistence of recurring flashes of light after a knock on the eye-ball, as from a tennis-ball, or the like, calls for careful examination and the need for physical rest. Apart from their occurrence in short-sighted eyes, flashes of light may be due to that very insidious disease, cyclitis—the inflammation in the ciliary body causing a minute pull on the front part of the retina. Therefore, the significance of flashes of light associated with misty vision is that the eye is probably the seat of cyclitis. Clearly the patient who experiences these flashes requires a very thorough examination of the eye; it is not a symptom to be regarded as trivial.

Dislike to light is more frequent than the preceding. This has a very varying significance. All are familiar with the intense photophobia and secondary spasm in the orbicularis that result from a corneal ulcer in a child, the spasm being more marked the more superficial the ulcer. It is always worth while in these cases to give a general anæsthetic, otherwise the force required to separate the lids to examine the cornea may do considerable harm. This may seem a too drastic procedure. But it is the only way to examine the eye thoroughly, and the anæsthesia is also useful for purposes of treatment. Short of this severe type, quite a number of people complain of inability to stand strong sunlight. Some of these will be found to have a fair complexion, fair hair, and more or less deficiency in the choroidal pigment, as seen by the ophthalmoscope. Frequently, too, they will be found to have a northern ancestry. It is this defect in the choroidal pigment that causes the dislike to light. It is important in considering this class of case to remember that the fair hair may become darker with advancing age, the pigmentation of the choroid, however, remaining deficient.

It is not always easy, but is sometimes very important, to distinguish this group from another group in which the symptoms are similar but are an expression of a neurasthenic condition—that is to say, people with a normally pigmented choroid and normal eyes may complain that they cannot stand bright sunlight or artificial light. It is very tempting to give these people tinted glasses. This, really, is the worse course to adopt, as they invariably require them darker and darker. They should be warned about this, and advised only to wear the tinted glasses on a very bright day.

Night-blindness usually indicates impaired nutrition or actual destruction of the retinal elements. It is a symptom of retinitis pigmentosa; it occurs also in syphilitic retinitis. In another group it is due to some general nutritional disorder, absence of fresh vegetables or vitamins, and these cases may be associated with a peculiar dry condition of the bulbar conjunctivæ. It is a well-marked symptom of scurvy, and was a familiar symptom when that disease was common. The symptom also occurs without any obvious retinal lesion as a congenital or familial disease. In this group the symptoms persist throughout life, but vision is not impaired. In the retinitis pigmentosa cases, vision slowly deteriorates and blindness ultimately results. In the war night-blindness was frequently complained of without any physical cause being discovered—a form of anxiety neurosis—the cause of which it is quite easy to understand. A form of night-blindness is experienced by very long-sighted people who wear strong convex glasses in the day-time with comfort but find they cannot see with them out of doors after dark. They should be advised to dispense with the glasses when out at night.

Seeing worse in a bright light is rather a striking and unexpected symptom, as it sounds odd to see better when the light is dull. It occurs usually after 45, and suggests tobacco neuritis or early optic atrophy, the strong light quickly fatigues the already exhausted nerve. In another and, perhaps, more common group, at any rate in private practice, the symptom is due to a small well-defined opacity in the lens, in the line of vision, usually at the posterior pole. Under the action of strong light the pupil contracts and the opacity then practically fills the pupillary area. The patient with such cataract will say that he cannot see anything on entering a room when he has to face the light, and his vision in the dark may suddenly turn to temporary blindness when he faces the headlights of a motor.

Colour-blindness is usually a congenital symptom. Acquired colour-blindness is a symptom of importance. It may be the earliest symptom of optic atrophy[*] or tobacco neuritis. Obviously an individual's habits or occupation will largely be responsible for the early recognition of this symptom. Artists, who are often great smokers, will notice it early, as will also gardeners or anyone who has to match colours.

Red vision occurs in two quite different conditions—in young school-children, and adults after a cataract has been extracted and cataract glasses have been worn. The child says the printed page suddenly looks red—the cataract patient finds the road, or sky, or trees looking red. Probably the explanation of the symptom is the same in both cases, the retinal vessels being situated in the anterior layers of the retina are traversed by the light on its way to the rods and cones. The eye is normally adapted for this red tinge, but if the vessels are congested, as they may be, from hypermetropia, or from too much light getting in the eye, in the absence of the lens the adaptation fails. The symptom is not serious and the treatment obvious. The cataract patient should avoid strong glare and use tinted glasses—the child should have the error of refraction corrected.

---

[*] Possibly indicating tabes.

Symptoms due to Refractive Errors and Defects of Accommodation.

The significance of the usual symptoms due to an error of refraction or defect in accommodation are sufficiently obvious and need not detain us, but there are some that are worth mentioning. Uncorrected long sight, in addition to producing the characteristic headache already referred to, is a common cause of head-tiredness and general fatigue, and may be a factor in causing irritability of temper. The point to remember is, that these persons do not complain of their sight, they see perfectly well, but examination shows their good vision is purchased by an abnormal effort of accommodation, and so it comes about that any depression of general health—for example, after influenza, or childbirth—brings these symptoms out and the temporary use of glasses may save much discomfort. I am often told that the patient has been advised to postpone having his eyes seen to until he is stronger. This is a fallacy. Glasses, by obviating the need for the constant effort of accommodation, help these debilitated people to recover more quickly. Similarly, children at the end of term complain in this way and are all right in the holidays.

The other point worth noting is that the defect of accommodation due to age (presbyopia) under average conditions begins at 45, and by 60 all accommodative power is lost. This means that reading glasses suitable for 60 should be suitable for the rest of life. Hence, when people over 60 begin to grumble at their glasses and demand stronger ones, the complaint is significant of some organic change in the eye, most likely early cataract, possibly senile choroiditis. The enterprising optician will supply the stronger glasses, and they may be of temporary benefit, but this course is not advisable until the fundus has been examined.

People about the age of 45 to 50 sometimes complain of an inability or difficulty in opening the eyes in the morning, not due to the lids being stuck together by discharge, they generally add that they have to lift the lids up with the fingers. This symptom, which may be called "*morning ptosis*," though sometimes due to ill-health, is frequently associated with uncorrected or insufficiently corrected presbyopia, and will disappear when proper glasses for close work are worn.

Double Vision and Multiple Vision.

Double vision should always be regarded as serious unless it be confined to one eye, a fact which should always be ascertained. It means something wrong with one or more of the muscles governing the eye movements and may indicate the beginning of serious disease of the central nervous system. A temporary form of double vision occurs sometimes after the eyes have been used for close work. It is not serious; indicates either the need for glasses or fresh glasses, and probably that the individual has been looking too close at the book or work, thereby producing over-convergence.

Multiple vision—for example, seeing three or more edges to the crescent moon or multiple lights when a single one is looked at—always signifies some early change in the lens. In this connexion there should be noted another symptom sometimes called "second sight." A person over 50 discovers that whereas he has hitherto had to use glasses for reading he can now do without them. This symptom is not so satisfactory as it seems. It means that some organic change is taking place in the lens, altering its refractive index. This change may or may not be visible with the ophthalmoscope. It may be due to glycosuria, and in any case of this kind the urine should be examined for sugar. If sugar be present the so-called second sight will be found to vary with the amount of sugar present at any particular time—that is to say, the ability to read without glasses will depend on the amount of sugar present. When sugar-free the patient needs his old glasses for near work. If he becomes careless about his diet the blood-sugar increases, the refractive index of the lens changes, and he can now read without glasses. Therefore, if an elderly patient complains that some days he is short-sighted and on other days he can see quite well at a distance, he is almost certainly the subject of glycosuria.

Closing one eye to read may indicate disease of that eye, but quite frequently is due to weakness of the power of convergence, a common condition in elderly people. The patient, knowing nothing of the real reason for his closing one eye, naturally concludes that that eye is the bad one and complains that he cannot see with it. As a matter of fact, he can see quite well with either eye separately, but not with the two together.

Nystagmus, Vertigo, and Vomiting.

A rare symptom to be mentioned spontaneously by the patient is that fixed objects when looked at appear to move or to be unsteady. This is due to nystagmus, it indicates that it is of recent origin; congenital nystagmus never produces this effect.

Vertigo may be, but only rarely is, due to defect in muscle balance, either a definite squint of recent paralytic origin, or one which, *up to the present*, has been rendered latent by an unconscious effort of compensation, but which now has become obvious owing to some weakness or debility making such compensation impossible. A vertical deviation is more prone to produce giddiness than is a lateral one. A simple test for ocular vertigo is to note if the giddiness disappears when one eye is shut. If it does, it clearly is due to some defect in binocular vision. Much can be done in some cases of ocular vertigo by the use of prismatic glasses.

I have not yet mentioned what is perhaps the commonest of eye symptoms. We often hear a patient complain of *his eye being weak*. The use of this term generally indicates an absence of clear thinking or accurate observation and an attempt should be made to ascertain what the patient really means. One will mean a watery eye, another that he cannot see small print, yet another that he cannot stand strong light.

Vomiting, I suggest, should be included as an ocular symptom. I have known more than one case of glaucoma in which vomiting, not failure of sight, was the symptom which made the patient seek advice. Vomiting may be due also to the use of too strong eserine drops, and may accompany, or perhaps mask, some injury to the eye. Although strictly speaking not an ocular symptom, it is worth noting that the use of atropine or hyoscine drops may in susceptible subjects produce the symptoms of general poisoning, giddiness, restlessness, and even delirium; to prevent or diminish the risk of such occurrence drops should be instilled at the outer canthus and not over the lacrymal punctum.

Papillitis.

Before concluding, I should draw your attention to what may seem an omission. You may have noticed that no mention has been made of papillitis (optic neuritis). Papillitis due, for example, to a tumour of the brain or to some toxæmic condition—renal disease or pregnancy—may exist for a considerable time without producing any effect on vision. Occasionally it may give rise to a *temporary* loss of vision, noticed, perhaps, on waking or on going from a well-lighted room to a darker one. The loss of vision may be so slight and temporary as not to call for much notice. The significance of these facts is obvious. The fundus should be examined in all cases of persistent headache, especially if it be of a severe character, even though there be no complaint of loss of vision. And similarly, if this apparently trivial symptom—temporary obscuration of vision—occur in the course of pregnancy associated with albuminuria, an examination of the fundus should be made at once. A timely termination of the pregnancy may prevent permanent loss of sight.

MINERS' NYSTAGMUS.[1]

By A. FREELAND FERGUS, M.D., LL.D.,
F.R.F.P.S. Glasg.,
CONSULTING SURGEON, GLASGOW EYE INFIRMARY.

The subject of miners' nystagmus has become one of considerable urgency on account of the numbers of men who are affected. It involves for them a period of bad health, sometimes of considerable duration and severity, and in addition there is an ever-increasing charge upon one of the most important industries of the country.

In the last few years the disease seems to have become much more prevalent than it was in my own student days. At the eye clinic in Glasgow, a town situated on the margin of the coal-fields of Lanarkshire and Dumbartonshire, a case of miners' nystagmus was occasionally seen, but very rarely. At that time there was no record kept by the State of the incidence of the disease. It was not within the province of any certifying surgeon. There was no miners' compensation, and therefore the State took no formal notice of its incidence. Accurate statistics have only been obtained within the last few years, and it is perhaps too soon to say whether the disease is definitely increasing or diminishing. Some time ago I communicated with the Ministry of Mines to know if the facts of the incidence of the disease had in any way been submitted to epidemiologists, and if any researches had been made as to the pathology of the malady, and I was told that no investigations in the latter direction had yet been carried out.

In this communication I desire to say something as to (*a*) the ætiology of the disease, (*b*) the management of patients afflicted with it, and (*c*) the legal aspects of the question.

Ætiology of the Disease.

Now, as regards the ætiology, there has been much excellent research work of a painstaking kind by numerous investigators in this and other countries. Great credit is due to many people, but particularly mention ought, I feel, to be made of the work of the late Mr. Simeon Snell, of Mr. Llewellyn, and more recently of Mr. Robson, so far as the United Kingdom is concerned. We have also had two Government reports on the subject, but I do not think that we have yet arrived at any certainty as to the causation of this malady. The origin of the disease has been attributed to such incidents in a collier's life as deficient illumination, constrained and cramped postures in working, inhalation of gases from certain kinds of coal. There can be no question as to the great merit of the work that has been done by numerous investigators, but, all the same, I fear that the verdict must be one of not proven.

To begin with, the connexion of miners' nystagmus with coal-mining is by no means a constant one. We have whole areas in which no cases seem to occur. It is very common in certain districts in the United Kingdom, very infrequent in others. It is common in some coal-fields on the continent, but is said to be unknown in the coal-pits of the United States and of South Africa. Now, in these areas there is no doubt that the miners work in cramped and strained positions. The illumination, of course, must be artificial, and presumably the chemical composition of coal, and therefore of the gases given off while it is being mined, is not very widely different in the different countries of the world. I have lately seen a case in which a miner had miners' nystagmus in Scotland. He went to the United States and worked there for some years, during which time he was quite free of the disease. On returning to Scotland and resuming work in the mine he was again attacked.

One remark must be made as to the change from what is known as the Glennie lamp to electric light. In my work as a medical referee I have frequently come across cases in which the sufferer from miners' nystagmus has definitely told me that the introduction of electric light was the first thing that made him give up working below ground. Up till the time of its introduction he had been able to work in comparative comfort with the ordinary Glennie lamp, but directly the electric light was introduced the glare made it quite impossible for him to continue at his occupation. That is a statement that I have very frequently received from colliers while examining them as a medical referee. To some extent the brilliant electric light seems to act as a detector of the presence of the disease. I am aware that it is maintained by trustworthy observers that the introduction of electric light has caused a diminution in the percentage of persons affected. I have no doubt as to the reliability and impartiality of the statements made, but I should be very glad to have accurate figures for the whole of the United Kingdom. I am not satisfied that all the painstaking work that has been done has solved the riddle, and therefore I have ventured to suggest that other lines of investigation, followed by persons who are competent for the work, might be of material assistance.

Symptoms.

My first proposition is that the disease is not one affecting the eyes alone, but that there are evidences of a more general involvement of cerebral centres. Everybody admits the characteristic movements of the eyes. Most people also know that there is a considerable amount of pain in the head. In my experience the pain is chiefly felt in the temples and forehead and in the occipital region. There are vertigo, muscular tremors, photophobia, night-blindness, and, in certain cases, special attitudes of the head; these are the usual symptoms with which everybody is familiar. There are other conditions which seem to me not to have received the attention which perhaps they should have received—namely, diminution of visual acuteness (in the proper sense of the term), and disturbances of the circulation. I almost invariably find the pulse rapid and weak and very frequently intermittent in rhythm. Such symptoms do not depend upon eye-strain. I can scarcely bring myself to believe that they depend upon illumination. It is perhaps conceivable that they may be associated with the long continuance of strained positions of the body, and I think they might also be associated with chronic poisoning by those gases on the action of which Mr. Robson, in his excellent monograph, lays stress, or by some other emanations of which we know nothing. It is because of this widespread involvement of nerve centres that it has seemed to me a possible explanation may be the presence of some micro-organism hitherto not discovered.

In May, 1924, as I have said, I wrote to the Mines Department, and learned that no investigations into the pathological conditions in persons suffering from miners' nystagmus had been made. I must say, considering the immense importance of the disease, alike to the sufferer and to the economic condition of the United Kingdom, I think it is high time that such investigations were made. No stone should be left unturned. The disease, so far as I know, is never fatal, but still post-mortem investigations might be made on persons who during life were known to have had it, and also there is no reason why, during the attacks, the condition of the cerebro-spinal fluid and of the blood should not be made the subject of investigation.

Diminished Visual Acuteness.

In a communication to the Ophthalmological Section of the Royal Society of Medicine,[2] I ventured to say that one of the most frequent symptoms was *diminution of visual acuteness*. Since that paper was given I have seen a very considerable number of patients, and I find the statement to be true. I am glad to be able to say that Mr. Llewellyn, in his able article in the *British Journal of Ophthalmology* for 1920, also mentions diminished visual acuity. I feel inclined to ascribe this defective visual acuteness to a central defect, and not merely to the oscillatory movements of the eyeballs. The visual acuteness remains defective even when the eyeballs are at rest between the paroxysms. I wish particularly to emphasise the fact that I use the word *visual acuteness* in the strict sense in which it ought always to be used. Visual acuteness is a matter almost entirely of macular function. At the conclusion of my communication, one of the gentlemen who took part in the discussion said that the vision in miners' nystagmus was not always bad, for he knew of a man with miners' nystagmus who could play a game of golf. That game does not require visual acuteness in the strict sense of the term, but only field vision. I have a near relative who has very defective central vision in each eye, who can only read with the aid of a strong magnifying glass and who has had on account of defective sight to study Braille, but who can fly-fish with some degree of success for trout and salmon. He can see the swirl of the water in the pool, he can see where the cast strikes the water, but he is quite unable to see the individual flies.

---

[1] A paper read before the Glasgow Royal Medico-Chirurgical Society on May 1st, 1925.

[2] Proceedings of the Royal Society of Medicine, vol. xviii.

One other observation in this connexion seems to me to be of importance. Coal-mining does not require visual acuteness at all, at any rate in the sense in which I use that phrase. At the Toronto meeting of the British Medical Association and on various other occasions I have called attention to cases which I have seen of patients who had 10 diopters or more of myopia and who still had no difficulty in coal-mining. Suppose we take 10 diopters—and I have known miners with a considerably higher amount—the distant point of distinct vision is at 4 inches from their eyes. I would expect a person with that amount of myopia, provided the eyes are healthy, to read small type at a distance of approximately 4 inches from the eyes but not at a greater. At the same time, while so employed, he can quite well, with his peripheral vision, make himself aware of the various objects in the room. It is this field vision which is used for coal-mining and for almost every other form of manual work. To attempt to express capacity for manual work or even for navigation in terms of visual acuteness is to attempt the impossible. I myself have a visual acuteness without my lenses of 6/36 in each eye but not more, yet, as a matter of fact, I can pick up a buoy quite easily at a distance of two or even more miles, and, when looking at the test-types from a distance of six metres without my glasses, I can locate quite distinctly the line of letters corresponding to the distance of three metres, although I cannot read them. I have no difficulty whatever in seeing that there are black marks on the card at that distance, and were these an object to be avoided I would have no difficulty in doing so. It is this function that is used in almost every kind of manual work, coal-mining included. For that reason I beg most respectfully to differ from Sir J. Purves-Stewart in his well-known and admirable text-book on "Nervous Diseases." He seems to base his theory of the oscillations of miners' nystagmus on the idea that coal-mining depends upon visual acuteness. It does not; it depends upon the more general function which we may call field vision. Visual acuteness I define as a function almost entirely macular, and it is that function which we investigate when we estimate the punctum remotum and the punctum proximum of vision by the use of test-types. The other functions of vision I think should be called field vision, and it is on this field vision that a labourer or a collier depends for his work.

A somewhat similar error was made by an ingenious member of our profession who, some years ago, with a view to testing the visual acuteness of young children, caused to be made certain sizes of white ivory balls, throwing them on the floor to see if the child could pick them up. That was not a test of visual acuteness. It may have been a test of differences of light perception or even of colour perception, but one thing it certainly was not, and that is a test of visual acuteness.

Circulatory Disturbance.

In the next place I want to say that in miners' nystagmus the pulse-rate is often very high. I think that from observed cases I have been justified in forming the opinion that the pulse-rate varies very much with the intensity of the disease. Very frequently I find it 100 or even more than 100. In one or two cases it has been as much as 120. I have only twice got a case, since I began these observations, under 76. The pulse is generally taken before the examination commences and after it is finished, and frequently the pulse is found to be a little slower, although not materially, at the end of the examination. Furthermore, it is often very weak in character and not infrequently it is intermittent in beat. That also I think clearly points to the fact that miners' nystagmus is something more than a disease of the eye.

Paroxysmal Nature of the Attacks.

But another striking feature in many cases is that the attacks of giddiness and of pain, and even of the movements of the eyeballs, are paroxysmal. A patient feels extremely well and goes about quite freely till all of a sudden he takes an attack of acute pain in the head with giddiness. Such attacks are apt to come on when the patient makes any effort at stooping or when he makes much exertion. To this I shall return when I come to speak of the treatment of miners' nystagmus. These three features, the diminution, in the large bulk of cases, of the visual acuteness, the disturbances of the circulation, and the paroxysmal nature of the attacks, seem to me to make it impossible to regard this disease as purely ocular in origin. It is not; it is a much more general condition affecting a large number of centres.

Now I think it quite possible that it may be due to the inhalation of certain gases or other emanations, but I have some difficulty in accepting this view. As has already been pointed out, there are huge areas where the disease does not exist. Further, I doubt very much if we would get the paroxysmal features in the attacks if the cause be gas inhalation. I wish plainly to say that I will not deny the possibility of its being due to the inhalation of deleterious gases, but I do say this, that there is a large field of investigation which does not yet seem to have been touched and which I think ought to be investigated by pathologists, bacteriologists, and epidemiologists. That seems to me a reasonable demand. From all I can hear the disease is increasing considerably in this country. Years ago there was very little of it. Were the cause either defective light or cramped position or gas inhalation it is difficult to believe that the disease would be unknown in some areas and abundant in others; nor is it likely that it would for long periods, in some cases for years, affect its victim in a paroxysmal manner.

Given a tolerable state of recovery, there may be no fresh exposure to defective light or to cramped position or to gas inhalation and yet there are fresh manifestations of the symptoms at intervals. If the disease were due to the three above-mentioned conditions then the number of cases occurring each year should be approximately a constant.

That this is far from being the case the undernoted figures show. These give the numbers of persons receiving compensation for miners' nystagmus in the United Kingdom for the years mentioned.

1913	*1914*	*1919*	*1920*	*1921*	*1922*	*1923*
2401	2774	2718	2865	1913	4902	3872

In looking into the matter the question has arisen as to whether this is not a comparatively new disease. When I was a student and a junior practitioner in the Glasgow Eye Infirmary we rarely saw any cases. Dransart, one of the early writers on the subject, mentions only a few, and in his communication

(*Annales d'Oculist*, 1877) says that Alf. Graefe had recorded three cases and Nieden five. Charles Bell Taylor, who for many years was a well-known ophthalmic practitioner in Nottingham, in his paper (THE LANCET, 1875) was only able to record three cases.

Before leaving this part of the subject there is just one other point that I wish to mention. Some patients have miners' nystagmus and suffer very little inconvenience from it. Prof. E. L. Collis (THE LANCET, Feb. 28th, 1925) says that oscillation of the eyeballs is present without causing inconvenience in from 20 to 30 per cent. of miners working with poor illumination. He lays much stress on the presence of a neurasthenic element as being of great importance. He does not define what he means by a neurasthenic element and, till he does so, the phrase, though convenient, is without meaning. It seems more rational to say that the symptoms manifested in any particular case are chiefly conditioned by the centres of the brain affected by some morbid process hitherto unknown.

I cannot help thinking that the symptoms in great part point to the mid-brain and the occipital lobes as being often involved. There is also frequently pain in the temporal region of each side of the skull which is perhaps accounted for by the fact that the centres for the movements of the eyes are at the lower aspect of each anterior ascending frontal convolution.

I cannot but regard the cause of miners' nystagmus as being at present unknown. Therefore I desire, as expressed in my communication to the Royal Society of Medicine, that other lines of investigation should be followed particularly by epidemiologists, bacteriologists, and pathologists.

Treatment.

I wish very briefly to discuss the treatment of this somewhat mysterious affection. Unfortunately, as a medical referee, I only see patients at a tolerably late stage of the malady, and therefore the following remarks are not made with that fullness of knowledge of the evolution of the disease which is possessed by many colliery doctors.

The point which has given me the greatest anxiety is to determine when a man who is the subject of the disease is in a condition to resume work. So widespread is the disease that it has become a serious question in the economics of coal-mining. To some extent I have gained assistance by dividing the cases that come before me into two groups. The first contains cases in which the pulse is not rapid—i.e., not above 80 or 85 per minute; in which there is little or no pain in the head, either frontal or occipital, and in which the vision, after careful correction of errors of refraction, is something better than 6/18. Again, it may be repeated that a coal-miner does not use visual acuteness in the true sense of the term. Visual acuteness in this true sense is the function which is examined when the distances of the punctum proximum and the punctum remotum from the eye are determined by types. The coal-miner, unless he be of a scientific bent and examines the fossils which are to be found in the coal, never uses visual acuteness in coal-mining. The importance of a diminished visual acuteness is that, if my opinion be correct, it indicates the involvement of the apices of the occipital lobes in the pathological process. A miner who is a slight case as above defined is, in my opinion, fit for a certain amount of light work, probably even at a colliery. Such work, however, should not involve much stooping nor anything which demands great physical exertion. It seems to me that it is very desirable to get a man who is a light case back to some work; but at first to such work as will not entail exhaustion of nerve centres. Here we are brought up against a double difficulty: there is no definition or even understanding as to what is meant by the phrase "light work"; nor, so far as I am aware, is there any arrangement whereby a man who is recovering from miners' nystagmus can work only part of a shift. I quite agree that there is often a mental factor in the case. When this is so, then regular work of a suitable kind will help very materially in promoting restoration to health, by restoring a man's confidence in himself, by allowing him to find out that he is able for some work.

Many of my colleagues, whose opinions are worthy of all consideration, aver that miners' nystagmus is closely analogous to shell shock. While not admitting the analogy I would like to ask this question of those who hold that opinion: Were they actually treating cases of shell shock would they transport their patients to a battle-field or subject them to the roar of artillery with the view of promoting their recovery? Perhaps the law might be altered to allow a larger selection of forms of employment for such men; agricultural work might be found to be very suitable, as it is work in healthy out-of-door surroundings. In cases in which good progress has been made towards recovery then work on the surface at a colliery might be undertaken.

The object of all treatment should be to nurse the patient back to a normal state of mental and physical vigour. With that end in view, as soon as possible some work ought to be undertaken. A friendly understanding between employers and employed as to kinds of work available would be of great service and in most cases the patient himself might be consulted as to forms of work which he feels capable of undertaking.

The case is quite different when the attack is severe. Given a patient with a quick and feeble pulse, with severe attacks of giddiness, with severe pain in the head, and with a diminished visual acuteness, then I think that the patient must be considered as being seriously ill and the greatest care must be exercised in certifying that the patient is fit for work. No doubt there may be every now and again a malingerer—malingering can scarcely produce a pulse-rate of over 100 per minute—but so far as I am able to form an opinion the large majority of these patients are ill and very often severely ill. It is always to be remembered that the attacks are frequently paroxysmal, and that therefore the symptoms vary very much in intensity at different times. When a patient has unmistakably the disease in this severe form he ought not to be definitely certified as fit for work.

A man with symptoms which point to severe exhaustion or disturbance of nerve centres should, generally speaking, be given a period of rest from labour. But here a new danger arises, and it is that a man who for many years has followed an active life may, when put on the shelf, become despondent, and the mental element thus developed may interfere, and that materially, with recovery. Unless in the severest cases, patients suffering from this severe form of the disease should take a certain amount of out-of-door exercise, preferably on some country road or in the fields. So long as the disease is severe they require a guide wherever there is traffic. The presence of a guide is almost necessary, for no one can tell when the patient will have a paroxysmal attack. Even on a country road the presence of a companion is desirable, for it gives the patient a sense of safety and in addition helps to abolish the introspection which a solitary walk is apt to engender. While ample rest should be given, every effort should be made to prevent the patient moping for days or weeks together in bed. Alcohol in every form should be prohibited, and so should such a depressant as tobacco.

I think it would also be advantageous if arrangements could be made for sufferers from this disease to be under regular medical supervision. No doubt many of them are frequently seen by their panel doctors, who, in colliery districts, are very familiar with the disease in all its aspects and are well fitted to care for the patients; I desire, however, that each patient shall be visited at least once every fortnight by his panel doctor or by some reliable substitute.

I do not think that at present there is any great need for special clinics for such patients.

Legal Aspect: The Question of Unfitness for Work.

In some respects I would alter legal procedure in these cases. If a man has miners' nystagmus to the extent of having to give up work, there can be no difficulty in certifying that he is unable to earn full wages at the work at which he was employed. I cannot see any alternative to the giving of such a certificate when the patient has had to leave off work. But there is no provision made, so far as I can interpret the prescribed form, to indicate that a particular case is a slight one, and that, although the patient ought not to work below ground, yet that he may be able for certain forms of light work above ground.

The present process is as follows. A patient feels difficulty in vision and he avails himself of the services of his panel doctor. The doctor in turn diagnoses nystagmus and sends him to a certifying surgeon, who examines the patient carefully and grants a certificate to the effect that the patient is suffering from miners' nystagmus; he also fixes the date when the incapacity began. Frequently an appeal is made from the certifying surgeon to the medical referee. This involves a third examination of the patient and not infrequently a journey of a good number of miles. The medical referee is always provided with a copy of the original report by the certifying surgeon from which he gains some useful information as to the condition of the nystagmus at the date when the certificate was granted. Perhaps the chief advantage in having a second opinion is that occasionally a miner may have a nystagmus which is not miners' nystagmus. The present writer has seen a case in which a miner had nystagmus but at the same time had disseminated sclerosis. Further, an experienced ophthalmic surgeon can examine eyes on many points—e.g., as to refraction and as to the presence or absence of heterophoria.

There is a good deal to be said against an appeal from one individual to another, and there is a somewhat widely spread feeling that the appeal should be to a panel of three. There is much to recommend this suggestion; it would, however, enormously increase the cost. Perhaps a simpler, less expensive, and equally satisfactory way would be for the certifying surgeon—whose certificate has been impugned—and a doctor selected by the employers to examine the workman together and draw up a joint report. In the event of their not coming to an agreement as to the facts, then and then only would the medical referee be called upon to act.

When an agreement as to the facts has been arrived at either with or without the aid of the medical referee, then the agreement should hold good for at least six months, during which time the patient should be exempt from further medical examinations.

When the patient has recovered to the extent of being able for something then he should begin with some light work for a few hours daily; to a large extent he should be allowed to choose the nature of the work, and it ought not necessarily to be at a colliery. My own preference would be for light agricultural work. I would hesitate long before I certified a patient with a pulse-rate of anything between 90 and 120 as fit for any work which would require either much stooping or such strong muscular effort as would exhaust the nerve centres.

Not long ago a judge had before him the case of a workman who was supposed, after a serious eye condition, to be doing light work as a watchman. It transpired that he went on duty every winter afternoon at 4.30 and was not relieved till 7.30 the following morning. There was a special dispensation at the end of each week—he went on duty at 4.30 on Saturday night and was not relieved till 7.30 on the following Monday morning. I do not know what the learned judge's decision was, but he and myself as assessor were of opinion that some people have queer notions of what is meant by light work.

Miners' Nystagmus in America.

Since drafting the above paper I have received some communications from America that seem to me of great interest. While making myself acquainted with the European literature on miners' nystagmus, I thought it right also to communicate with a few friends on the other side of the Atlantic. I wrote to Prof. McCallum, the well-known biochemist in Montreal. He has, with great kindness, promised to communicate with persons connected with the coal industry in Canada, but as yet he is not in a position to give me any report on the matter. I also communicated with Dr. Duane, of New York, and with Dr. Webster Fox, of Philadelphia. Dr. Duane, in acknowledging receipt of my letter wrote, on April 10th of this year, as follows: "Miners' nystagmus is certainly rare in this country, as is shown by the total, or practically total, absence of reference to it in our literature. Apparently even in the coal-fields of Pennsylvania, where one would expect it, it is rare. I myself have never seen a case that I can recollect." Dr. Duane has very kindly promised to get me further information and is, I believe, having investigations made as to the conditions in the Pittsburg coal-pits.

I am deeply indebted to Dr. Webster Fox for kindly forwarding to me some literature published in America. He has sent to me four numbers of the Monthly Review of the U.S. Bureau of Labor Statistics, and, in addition, he has sent a very interesting paper entitled Miners' Nystagmus, by Frederick L. Hoffman, printed by the Government Printing Office, Washington, in 1916. This particular publication is one of great value. It is a very full and painstaking discussion of the whole subject, and the bibliographical references are of great importance because they are very full. I do not think I have seen a better synopsis of the history of miners' nystagmus than is contained in this publication. The author mentions, amongst other things, all the important work that has been done in Europe, giving full details of the very painstaking and elaborate researches of Llewellyn and Snell and Nieden, and of a considerable number of other Europeans who have written on the subject. What strikes me in these contributions coming from the United States, is that they all deal with European nystagmus, and the disease is almost never mentioned as occurring in the United States. So far as the information derived from the literature which I have perused throws any light on the subject, it is a disease practically unknown in America. There is one statistical investigation mentioned as having been conducted in Illinois. Five hundred miners working under conditions which would render them liable to nystagmus in this country were carefully examined and not a single case of miners' nystagmus found.

Hoffman, in his summary at the end of his contribution, has this important sentence: "No reasons suggest themselves, however, why this peculiar affliction should be limited to mining districts of European countries and not be found in American coal-mining districts, where, on account of the gaseous nature of the mines, the use of safety-lamps is compulsory." This sentence throws grave doubts on any theory of defective illumination being the cause. If safety-lamps produce nystagmus in the United Kingdom why do they not do so in the United States? Why have the hopes that electric lighting of coal-pits would abolish nystagmus not been fulfilled? If the inhalation of gas be the cause in South Wales and elsewhere why do the gaseous conditions of the pits in America not produce similar results?

THE TREATMENT OF GENERAL PARALYSIS AND TABES BY TRYPARSAMIDE.

BY W. S. DAWSON, M.D. OXF., M.R.C.P. LOND.,
SENIOR ASSISTANT MEDICAL OFFICER, MAUDSLEY HOSPITAL.

REMARKABLE results have been published in America from the use in syphilis of the nervous system of a new arsenical compound, tryparsamide, supplied by the Rockefeller Institute. This drug, which is a sodium salt of N-phenyl-glycineamid-p-arsenic acid (containing 25·0 per cent. of arsenic), was first prepared by Jacobs and Heidelberger in 1915. Experiments have shown that it has peculiar properties. Its spirochæticidal action is relatively feeble, but it has a marked tonic effect, it promotes recovery from toxic injury, and induces the healing of syphilitic lesions without increasing the liability to a generalised spread of the spirochæte. At the same time it has very little local or general irritant action upon the tissues, and cumulative effects are infrequent. Moreover, experiments indicate that it has a greater power of penetrating into the cerebro-spinal fluid than other arsenical preparations. The drug appears to be of value also in both human and animal trypanosomiasis. The sole disadvantage is a tendency to cause amblyopia which is usually transitory, but may rarely be permanent.

Through the kindness of Sir Frederick Mott a supply of tryparsamide from the Rockefeller Institute became available early last year at the Maudsley Hospital for the treatment of suitable cases of general paralysis and tabes. The number of cases treated up to date is, unfortunately, small, but it has been thought worth while to publish these results, a preliminary report upon which has already been laid before the Medical Research Council.

Type of Case under Treatment.

The cases were obtained from various sources. Some were referred by general practitioners or from other hospitals and infirmaries specially for this treatment, while others attended the out-patient department for the relief of symptoms which investigation proved to be due to neuro-syphilis. As this hospital is intended for early forms of mental disorder, and as all patients before admission must be capable of signifying their desire to undergo treatment, the cases in the present series were, for the most part, early, and the mental symptoms on admission comparatively mild. As will be seen, some had later to be sent elsewhere for detention under certificate. Beyond the fact, then, that the mental symptoms on admission were not so severe as to render removal to an asylum imperative, the cases were not specially selected. They are, on the whole, comparable to those reported by Lorenz, Loevenhart, Bleckwenn, and Hodges.[1] To quote these observers :—

> " In our work we include under paresis any case of syphilis of the central nervous system that has a certain physical symptom-complex and which is associated with definite mental symptoms of sufficient severity to warrant the conclusion that a psychosis exists. This psychosis may be varied in its symptoms ; most common is a general dilapidation shown by a lessened interest and capability with a proneness to confusion and faulty memory for recent events associated with an emotional instability bordering on a child-like happiness or simplicity. These placid mental states are frequently interrupted by sharp periods of excitement. In some cases a manic-like picture is seen, but most common and characteristic is a feeling of happiness or well-being. This may be actually expressed or evidenced by conduct and may be inferred from the topic of conversation selected by the patient or his general manner of speech. The carelessness and indifference of the patient relative to his immediate circumstances or the future are also characteristic mental symptoms of paresis. The classical picture of megalomania or delusions of great wealth, great physical strength, or great attainment are relatively uncommon to-day. This is probably due to our recognising paresis without these expansive ideas that were essential for the clinical picture as recognised years ago. To sum up, in the mental symptoms associated with the physical signs of tremors, disturbed deep reflexes, pupillary anomalies, speech defects, &c., that complete the picture of paresis, most stress would be laid on definite changes in character or personality, mental or intellectual indolence, mild or marked euphoria, memory disturbances, confusion, excitement, delusions, hallucinations, &c. In addition to this syndrome, a completely positive serology in both blood and spinal fluid in an untreated case adds the other elements essential for our diagnosis of paresis."

It will be seen that most of the cases described in the present series display features answering to the above description.

Method of Treatment.

In addition to the ordinary physical, mental, and serological examination special attention was paid to the condition of the optic discs and visual fields. In no case, however, was there detected any marked disturbance of vision either before or after treatment. It is to be noted that the cases of amblyopia reported had all received larger doses of tryparsamide than were given in the present series. In order that the drug might specially be tested, neither mercury nor bismuth was given, although these are said to intensify the action of tryparsamide. The drug was given in eight weekly doses of 2·0 g. dissolved in 5-10 c.cm. of distilled water intravenously or into the muscles ; the latter appears to be preferable as it is less quickly eliminated from the system. There is very little local irritation even when the drug is spilled outside the vein. Nor was there any general reaction except in one case who had a rigor several hours after one of his injections.

Table of Pathological Reactions Before and After Injections (First Course).

	40	(*c*)	(*c*)	(*c*)	(*c*)	Imp.

* Third course. Ex., excess.

(*a*) Contaminated with blood. (*b*) Contained some blood. (*c*) Positive; specimen contaminated.

Note.—The cerebro-spinal fluids were put up for the Wassermann tests in amounts of 1·0, 0·5, 0·3, and 0·2 c.cm. The amount of protein was estimated by a nephelometric method, 40–80 mgr. % being considered normal.

Details of Cases.

1. Male, 29. *General paralysis.*—Discharged from a mental hospital in May, 1923, having recovered from, and gained insight into, an acute delusional state. In October, 1923, was noticed to have deteriorated mentally, and was also hallucinated for sight and hearing and had a slight seizure. Threatened to strangle his wife and was taken to the infirmary. November, 1923, admitted to the Maudsley Hospital. He was then distinctly fatuous and unable to understand fully why he was admitted to hospital. He was injected with malarial blood and had eight good rigors. By March, 1924, he had improved mentally and physically and was able to employ himself in simple tasks, but was not able to do the work to which he had been used. He displayed a normal interest in his progress and treatment. He was in good physical condition, with slight tremors of lips and tongue. Reflexes all rather brisk. Coördination and sensation unimpaired. Pupils unequal and sluggish to light and consensual reflex. After a course of tryparsamide there was no evident mental change, but the pupils became inactive to light and consensual reflex. He is now in a Pensions Hospital and recently showed no material change.

2. Male, 35. *Tabes.*—Gastric crises for a year, latterly accompanied by great agitation and emotional display. Had received 6 g. of N.A.B. with little effect on serology beyond slight reduction of Wassermann, cells, and Lange curve. On admission nutrition good. Reflexes all present. Pupils unequal and sluggish to light, but brisk to accommodation. Improved during treatment; crises became less severe and less frequent, but patient complained of continual ache in epigastric region. Course of injection was repeated with some benefit. He has been at work for six months and feels perfectly well.

3. Male, 35. *General paralysis.*—During 1920–23 had several courses of salvarsan. In September, 1923, became depressed and very constipated, and developed numerous hypochondriacal ideas. On admission nutrition fair; tremors of tongue and lips. Reflexes all brisk. Coördination and sensation normal. Pupils contracted, equal, inactive to light and consensual reflex, very sluggish to accommodation. Facial expression that of melancholia with typical wrinkling. Mental state also that of melancholia. After treatment the pupils were unaffected, but later the depression and the constipation cleared up and the patient has now resumed his normal activities.

4. Male, 32. *General paralysis.*—Was taken up by police wandering in street and expressing numerous delusions, certified and discharged after nine months with apparently complete mental remission. Referred to the Maudsley Hospital for a course of tryparsamide. On admission in good health, slight lingual tremors, tendon and cutaneous reflexes all brisk. Pupils unequal, and inactive to light and consensual reflex; right pupil sluggish to accommodation, left inactive. After course of injections physical signs unchanged and mental condition remained normal. Has been at work since distributing papers by motor van for several months and has remained well up to present. He is receiving a third course of injections as an out-patient.

5. Male, 41. *General paralysis.*—Sudden onset with excitement and delusions. Was in mental hospital for six months and was discharged with incomplete remission. On admission to Maudsley Hospital, a little euphoric, and lacking complete insight into his condition. Memory defective for recent events. Nutrition fair. Tongue and lip tremulous. Speech slurred. Tendon and cutaneous reflexes brisk. Coördination a little impaired. Pupils unequal, irregular, and sluggish to light. During treatment put on weight, but deteriorated mentally and physically and became dull and fatuous. Relapsed after being sent home and had to be taken to infirmary. He is now at home but his intellect is definitely impaired. The C.S.F. gave a negative Wassermann after a second course of injections.

6. Male, 39. *Tabo-paresis.*—Has felt "nervous" since 1919; for at least two years there has been steady deterioration and very evident loss of business acumen. On admission he was euphoric, very childish, fatuous, poorly orientated, and amnesic. Nutrition good. Marked labial, lingual, and digital tremors. Speech slurred. Knee- and ankle-jerks absent. Rombergism +. Pupils unequal, irregular, and inactive to light and consensual reflex. Deterioration continued and he was removed to an infirmary.

7. Male, 58. *Tabes.* — Christmas, 1923, complained of backache and in the course of a week or so lost use of legs. On admission very emaciated. All tendon jerks absent; arms and legs very ataxic. Pupils equal and active to light and accommodation. Deteriorated mentally and physically, and became steadily more helpless. Post mortem showed advanced arteriosclerosis; typical degeneration in dorsal columns of cord. Brain not obviously affected, but microscopical examination showed perivascular infiltration of small cells and a certain degree of neurotic degeneration. The C.S.F. in this case was negative both before and after treatment but gave a luetic Lange reaction. He also had a carcinoma of the lower end of the œsophagus, without secondary deposits.

8. Male, 54. *General paralysis.*—Few months ago became depressed, worried, restless, and forgetful. On admission emotional and confused, poorly orientated, and amnesic. Physically in poor condition. Marked lingual and digital tremors. Speech slurred. All reflexes exaggerated. Sensation and coördination normal. Slight paresis right arm; tongue protruded a little to the left. Pupils of medium size, regular and active consensually, and to light and accommodation. During treatment became less confused, but is now distinctly dull and has evidently deteriorated. Physically he has improved, has increased in weight, and the paresis has cleared up. The tremors persist and the pupils react sluggishly.

9. Male, 31. *Tabo-paresis.*—Onset in July, 1923, with attack of confusion. Became acutely excited and was in mental hospital up to May, 1924, during which time he had malarial treatment. He improved enough to be discharged and was admitted to the Maudsley Hospital for a course of tryparsamide. On admission he was in fair condition. There were marked tremors of face, tongue, and fingers. Speech a little slurred. Knee- and ankle-jerks absent. Rombergism slight. Pupils unequal, irregular, and sluggish to light and consensual reflex. Mentally he was exalted and overactive. During treatment he increased greatly in weight and became less tremulous; physical signs otherwise unchanged. Mentally he became dull and distinctly vegetative and had evidently deteriorated. He is living at home and has received a second course as an out-patient.

10. Male, 59. *Tabes.*—Complained of headache and "shakiness" since attack of "influenza" in December, 1923. Also gave history of "washing-basin" sign. On admission no evident mental disturbance. General nutrition good. Slight lingual and digital tremors. Knee- and ankle-jerks absent. Rombergism +. Pupils myotic and inactive to light and consensual reflex. During treatment complained less of headache and felt much better. Physical signs unchanged.

11. Male, 26. *General paralysis.*—In 1920 was discharged from the police for being asleep on duty. Has done occasional work up to August, 1924, when he began to have "fits." Later was taken to infirmary with "status epilepticus." Referred to Maudsley Hospital for opinion as to relation of old G.S.W. head to the "fits." Mentally rather childish and a little overactive, and at the same time very easily irritated and apt to take offence. Speech a little slurred when he became excited. Right knee- and ankle-jerks definitely less brisk than the left. Pupils a little irregular but reacted normally. Optic discs normal. There is a very

slight depression in the right parietal bone. After course of injections became much more stable but is still rather childish.

12. Male, 48. *General paralysis.*—Had syphilis 30 years ago. Indulgence in alcohol and smoking with "high pressure life" for years. Several attacks of giddiness recently which culminated in a mild confusional attack during which he was brought to the hospital. His pulse was then uncountable; there were no other physical signs. Next day he was mentally clear and gave a good account of himself except for the events of the three preceding days. Heart dilated, pulse 150, regular. Electrocardiogram showed 2 : 1 heart-block with auricle 360, ventricle 180. After course of Nativelle ampoules he developed auricular fibrillation, and on cessation of digitalin injections the heart became slow and regular and has remained normal since (seven months). In view of old infection, blood and C.S.F. tested and found to give positive Wassermann. He presents no physical or mental signs at present, but the serology has not appreciably been affected by a course of tryparsamide.

Summary of Results.

(*a*) *Clinical.*		(*b*) *Serological.*	
Improved	13	Improved	7
Not improved ..	5	Not improved ..	11
Died..	2	Not improved, died	2
	20		20

Several cases who showed both clinical and serological improvement at the end of the first course of injections have received second and third courses at intervals of about two months. Their improvement has been maintained, and two (Nos. 1 and 5) now have a negative Wassermann in the C.S.F., although the Lange reaction is still slightly positive. It is to be noted that both clinical and serological improvement may continue for some time after the completion of a course of injections. The condition of the patient at the end of treatment and the reactions of his fluids are not to be accepted as the final result; the drug continues to exert a beneficial effect for some weeks afterwards. It has been noticed that the skin becomes clearer and the general bodily condition improves under the "tonic" action of tryparsamide, which has been remarked upon by American workers. However, as these patients have been under observation for less than a year their ultimate fate remains to be seen. No. 12 is of special interest as his heart condition was quite severe enough to account for his confusion, and he has never shown any neurological signs of paresis in spite of the reactions of his fluids, and of the fact that they were not influenced by tryparsamide. One case of tabes (No. 2), who had had very severe gastric crises for over a year in spite of intensive treatment with mercury and N.A.B., is now, after two courses of tryparsamide, back at work and feels perfectly well although physical signs persist. Dr. Aileen Boyd, working in the laboratory at this hospital, has confirmed the observations of American workers that arsenic may be detected in the C.S.F. for two or three days after an injection of tryparsamide.

As regards the diagnosis of the cases in this series one may recall the words of Head and Fearnsides,[2] who stated :—

> "It is quite impossible, in many cases, to diagnose the difference between syphilitic encephalitis and dementia paralytica without observing the effect of treatment and the changes it produces in the Wassermann reaction . . . Numbers of persons suffering with cerebral syphilis are condemned to die untreated because they are thought to be suffering from 'general paralysis,' when in reality they are examples of a curable disease. No complete diagnosis or prognosis can be made until the patient has been observed and treated for at least six months, and the C.S.F. has been systematically examined from time to time."

In no case in this series was there produced any remarkable result such as might not possibly have been obtained by the administration of other arsenic compounds. Several cases of paresis appear to have had their downward course arrested, while others have improved to a lesser extent. Whether tryparsamide is really more potent than other arsenicals is not proved in this series of cases, but the drug is certainly worth further trial. It is easy to administer and does not appear to be toxic in the doses used.

Finally, I wish to record my thanks to Sir Frederick Mott for his help and for the interest he has shown in this investigation; to Dr. Edward Mapother, the medical superintendent, for his permission to publish these cases; and to the staff of the laboratory for the pathological investigations and other help.

THREE CASES OF UNUSUAL FORMS OF LIPOMATA OF THE BREAST.

BY DUNCAN C. L. FITZWILLIAMS, C.M.G., M.D., CH.M., F.R.C.S. ENG.,
SURGEON TO ST. MARY'S HOSPITAL, PADDINGTON, AND PADDINGTON GREEN CHILDREN'S HOSPITAL.

IN an organ such as the breast, which consists so largely of fat, which has fat for its supporting tissue filling out all the interstices between the lobes and the lobules, which is embedded in fat, it is no wonder that we frequently meet fatty tumours. These may arise in the fat over the breast, in the fat under the breast, or in the fat inside the capsule of the breast. The last form is the rarest. What it is that determines the growth of a fatty or other simple tumour is unknown, but we imagine that it is something which differs from the stimulus which causes the growth of a malignant tumour. It is therefore always interesting to find both a malignant tumour and an innocent tumour in the same person, and doubly so when they occur in the same organ.

In the first case reported there was a local intramammary lipoma and a scirrhus tumour in the same breast. In the second case there was a large diffuse intramammary lipoma occupying and distending both breasts. In the third there was a fatty tumour in one breast and a scirrhus in the other. The lipoma showed the unusual occurrence of the deposition of calcium salts in the fatty cells.

CASE 1.—L. S., aged 54, was admitted to St. Mary's Hospital on May 5th, 1924, complaining of a lump in the breast.

History.—A lump was first noticed in the left breast about two months ago. About six weeks ago she had a fall and bruised her ribs and back; as a result of the fall the breast was very painful and she applied hot fomentations. No diminution in size has taken place since then.

Condition on Examination.—A lump about the size of a walnut could be felt deeply situated in the upper and outer quadrant of the breast. It was fairly hard and seemed to be attached slightly to the pectoralis major muscle, it was free from the skin, and there was no retraction of the nipple. Small glands could be felt in the axilla. Until Christmas her periods had been regular, since then they had ceased. The left side of the lump seemed distinctly tender. The mass was believed to be innocent.

Operation.—On May 10th a circumferential incision was made round the lower margin of the breast and the breast removed subcutaneously, leaving the nipple. The axillary tail was divided with the cautery. A drain was placed in the wound for 24 hours. She left the hospital with the wound healed in ten days' time.

Pathologist's Report.—The tumour removed from the breast proved to be an encapsuled lipoma about the size of a ping-pong ball, in which the fat was bright yellow in strong contrast to the pale fat in and surrounding the breast. At one side of the fatty tumour, apparently adjacent to or actually in its capsule, is a hard area which on section appears like a rotten pear. This mass, which was the size of an ordinary grape, proved to be a carcinoma spreading actively at the periphery. The breast showed chronic mastitic changes throughout its substance.

Intramammary lipomata are so rare that even their very existence was denied till lately, and Gross says, "I am not aware of a single case of circumscribed lipoma occurring in the gland itself," a statement which is concurred in by Bryant in 1887. We know, however, that they do exist both in the localised and in the diffuse form, and this is a very good example of a localised tumour. The fat of which it was composed appeared to have no relation to the fat in the surrounding breast or in the breast capsule, being of a strikingly different colour. Delage reported a case where multiple intramammary lipomata were found, the breast being described as feeling like "a bag of oranges," and later five separate tumours were removed from the breast. In this case, however, a lipoma had been removed from the breast some ten years previously, and I strongly suspect that some small lobules of the original tumour may have been torn off and remained in small loculi of the capsule and developed into five separate tumours later. It is a possibility to be considered.

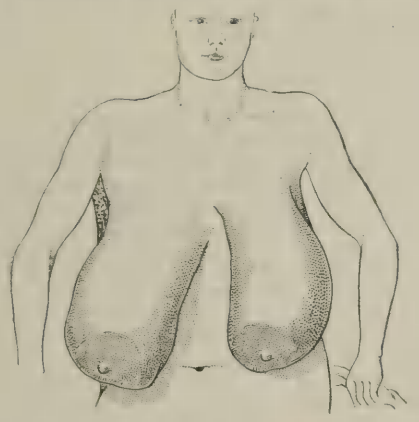
---

[2] Head, H., and Fearnsides, E. G.: Clinical Aspects of Syphilis of the Nervous System, Brain, September, 1914, xxxvii., 1.

The lipoma in the above case appeared to be the original tumour and the malignant growth to have followed it. From what we know of the origin of malignant growths from chronic irritation it is only natural that we should suppose that this malignant growth was initiated by the irritation of an abnormal growth in the neighbourhood.

CASE 2.—Mrs. C., aged 41, was sent to see me by Dr. G. A. Finegan on March 28th, 1922, on account of the large size of her breasts.

History.—For two years both breasts have been getting larger, the right more so than the left. She has experienced a dragging sensation and shooting pains in both breasts during this time. The breasts became larger, more uncomfortable and painful at the periods, and lately this has been more marked, and the pain has changed to a more disagreeable character.



Previous History.—She has had one child, now 12 years old; this she suckled for ten months. Sixteen months later she had a miscarriage at the fourth month; no other pregnancies.

Condition on Examination.—The breasts were both very large and pendulous. (See figure.) One could not quite class them with the huge breasts of parenchymatous hypertrophy, but they were approaching that condition. Over the left breast the veins were the more prominent. Both breasts felt irregularly lumpy, but there was nothing else to be made out. There was no discharge from the nipples which she said had always been of large size. She was put upon a course of tablets of polyglandin.

July 16th, 1923: She was seen again and the breasts were certainly smaller, but still very bulky and pendulous. The right measured 15½ inches and the left 14 inches in circumference at the level of the costo-mammary groove. The nipples were 5 inches across. The veins were still prominent over the left breast. As she was now tired of the continual drag of the breasts and was unlikely to have any more children she expressed a wish to be rid of them. Operation was performed on the 27th and both breasts were removed by flaps. On cutting the breast tissue one was surprised to find that the knife only passed through adipose tissue, no gland substance being visible, and there was a complete absence of the white-looking tissue met with in hypertrophy of the breasts. About 3 lb. of this fatty tissue was removed from each breast. There was no capsule and the fatty tissue permeated the whole gland. The flaps left a sufficiency of breast tissue to fashion shapely breasts and enough skin to cover them, the flaps being planned so that the scar should lie in a circular manner at the lower border of the newly-shaped organs. The operation proved eminently satisfactory, and the patient had a very presentable figure. The nipples were removed, but as they were nearly flat from the stretching of the skin and the immense areolæ were very pale, it was not a noticeable loss. The wounds healed easily.

Pathological Report.—On coronal section the tumours had a circular appearance surrounded by skin, and were 8 by 6 inches across. They had the appearance of ordinary fatty tissue through which coarse greyish strands could be seen running. These strands appeared to the naked eye to be ordinary fibrous trabeculæ. On microscopic section, however, these strands proved to be the compressed remnants of the breast tissue, showing that the fatty tissue had collected in the interlobular and interlobar spaces. There was no capsule to the fatty tissue which was diffused throughout the whole gland, and did not differ either in colour or structure from the ordinary mammary fatty tissue. The condition was evidently a diffuse intramammary lipoma.

Case 2 is a type of the diffuse intramammary lipoma. It is a form of tumour which is excessively difficult to diagnose, as it has no edge or limit, and appears to be hypertrophied breast tissue. It is remarkable in that it was bilateral. In this case, as in Begouin and Haekel's cases, the essential tissue of the breast was split up into small islets lost in the fatty tissue. Whether this condition prevents the breasts from functioning is unknown, as no cases have been reported, but these separated ducts have been known to become distended with a thick milk-like fluid.

CASE 3.—A widow, R. L., aged 70, was admitted to St. Mary's Hospital on June 16th, 1924, with lumps in both breasts.

History.—Patient had known of a soft lump in her left breast for more than eight years. It never gave rise to pain or troubled her in any way, so that she took no notice of it. For the last eight or nine months she had noticed the right breast getting smaller and a lump gradually forming. There were no symptoms till about a month ago, so she took no more notice of it than of the lump in the other breast. During the last month, however, she has had slight pain and there has been a slight discharge.

Condition on Admission.—The left breast contains in its upper and inner quadrant a soft fluctuant mass which is obviously a lipoma. The right breast is atrophic, but there is a tumour the size of a bantam's egg to the inner side of the nipple. The tumour is stony hard, quite fixed to the skin, and to the muscles underneath. The skin is discoloured over the mass, and is ulcerated at one spot. It seems to have incorporated into itself nearly all the breast tissue and the strongly retracted nipple.

Operation.—The lipoma shelled out easily. The bulk of it lay superficially between two lobes of the breast, apparently outside the breast tissue, but there were two lobulations which extended well down between the lobes of the breast, so that it was impossible to say whether it had originated inside or outside the breast capsule. It seemed to me, however, that it would be easier for the tumour to have started inside the breast and have spread to the outside, than to have started outside the breast and to have sent two prolongations into the breast substance through the capsule. The right breast was removed by a radical operation. The lipoma, which measured about 2 by 1 by 1 inches, was an encapsuled mass of bright yellow fatty tissue which presented nothing peculiar to the naked eye. On section, however, numerous areas were seen where calcium salts seemed to have been deposited in the fatty contents of the cells. The carcinoma was of the hard scirrhous type.

In this case the association between the malignant and the benign tumour was probably accidental, the first being in one breast and the second in the other. What is interesting, however, is the deposition of calcium salts in the fatty tumour. Sick reported a fatty tumour from the breast of a woman which contained areas of hyaline cartilage in the lipomatous tissue. In Guy's Hospital museum there is preserved a "large adipose tumour, which measured 23 inches in circumference, and was removed after death from the breast of a married but sterile old woman, aged 87. When 30 years of age she observed the tumour in the upper part of the right breast, and this she showed to Sir Astley Cooper on Jan. 9th, 1806. She remembered the date, because it was the day on which Lord Nelson was buried. . . . When a section was made it was found to consist of fat, with a piece of bone in the centre." Most of the bone-containing tumours of the breast are either sarcomata or very closely allied to them, but as this tumour had been known for 57 years we may suppose its innocent nature. It is, however, significant that sarcomata have been known to become fatty, and one such tumour was shown before the Royal Society of Medicine, Section of Surgery (vol. xiv., 1921, p. 33). Chipault noted a pendulous lipoma the size of two fists growing from the inner surface of the thigh of a woman of 69, which had been present for 29 years. On section after removal this was found to be a lipoma calcified in parts.

DIABETES, SURGICAL INFECTIONS AND INSULIN.

By R. CARRASCO-FORMIGUERA, M.D.,
ASSISTANT, "INSTITUT DE FISIOLOGIA"; DIRECTOR,
"SANATORI PER A DIABETICS," BARCELONA
(CATALONIA).

My object, in the present paper, is to consider one of the many problems related to the use of insulin in the surgical complications of diabetes, basing my observations on a series of 53 such cases [1] in which insulin has been employed.

So high an authority as Dr. E. P. Joslin has expressed on this question the following opinions: "Serious infections occurred with several patients and in these insulin was of no avail" [2]; "It has been recognised that the urine would not become sugar-free in the presence of an infection, even with insulin at liberal doses" [3]; and "*When dealing with infections a rigorous attempt should not be made to get the patient sugar-free either before or after operation.* This is seldom possible and, even if attained, is secured at too great a loss of body tissue."[4]

Despite the authority of Dr. Joslin, whose pupil I am proud to be, and to whom I am indebted for most of my knowledge of diabetes, I have found from the beginning that the above-mentioned views are not sufficiently substantiated by the facts on which they seemed to be based. If Dr. Joslin's somewhat pessimistic conclusions are not correct it might happen that a given patient would be left to die, whose life might be saved by rendering his urine sugar-free or the blood-sugar normal by means of insulin, given in doses large enough and distributed in a sufficient number of injections. It is therefore very important to decide: (1) whether the metabolic derangement induced by infection in some cases is really so profound as to render it impossible to make the blood-sugar normal by means of insulin or whether, on the contrary, insulin in sufficiently large and properly distributed doses might not, in all cases, accomplish that result; and (2), on the assumption that it is possible, whether it is all-important or not to attain absolute sugar freedom in urine or even a quite normal blood-sugar level in cases of surgical infection in diabetic patients.

As to the first point, the actual clinical facts that Dr. Joslin presents in support of his views are the following. In the case of a young man with septicæmia no effect, beneficial or otherwise, was noted with the 77 units which he received during eight days. In a case with erysipelas who, before the infection developed, was kept sugar-free with 12 units, a much larger daily dose was without effect. In a case with cerebro-spinal meningitis insulin was discontinued when the true diagnosis was made, after 30 units of insulin had been given in two injections, and glycosuria persisted to the end.[5] Finally, even 80 units of insulin failed to free the urine of sugar in a diabetic suffering with carbuncle.[6]

In all this there is nothing to show that what was not obtained with 80 units daily, or less, in the cases just mentioned might not have been obtained with higher doses, distributed in a sufficient number of injections. That this is very probable is suggested by a very interesting case recently reported in The Lancet by R. Owen-Jones,[7] who expresses the same opinion, and also by my own experience in cases such as Nos. 155, 218, 178, and 403, amongst others, of my series.

Clinical Records.

Cases 155 and 218 suffered with necrotic cellulitis of a lower limb, subsequent to infection of slight wounds. When I saw them for the first time both were in a very serious condition. In both the disappearance of glycosuria was obtained, but not before so much as 110 units in five injections, in Case 155 (also in September, 1923), and 176 units in eight injections in Case 218 had been given in 24 hours. Both patients died from septicæmia (pneumococci and tetrageni respectively), and the last specimens of urine passed were sugar-free, the dose in the last period of 24 hours being not less than 200 units in Case 155. Case 178 died from peritonitis after being operated on for perforated gangrenous appendicitis. Before the attack of appendicitis the patient was sugar-free (with insulin); before the operation there was a slight glycosuria; immediately after the operation, which was performed under ether and with adequate insulin preparation, the urine was sugar- and acetone-free; some hours later glycosuria was again present, in a rather intense degree, but with the aid of insulin it decreased again, and before death occurred, about 30 hours after the operation, the urine was sugar-free and remained so to the end. I cannot tell the exact amount of insulin that I injected, but it certainly was well above 80 units in 24 hours.

Despite the facts just mentioned I began to think that Dr. Joslin might be right in the point under consideration when, in Case 281, which I saw for the first time in an extremely grave condition, with acute gangrene of one foot and septicæmia, insulin, in doses of about 30 units every eight hours, continued until the patient's death, 36 hours after amputation, failed to change the apparent intensity of the reaction obtained with the Benedict test. This doubt was strengthened when the same failure recurred in Case 403. This patient had a carbuncle at the back of the neck that had been operated upon two days before without previous insulin treatment, and very severe glycosuria and acidosis subsequently developed. The administration of 180 units of insulin in seven injections, in a period of 21 hours, was unsuccessful. But finally, when 240 units had been administered in nine injections in a period of 31 hours, during which no food was given, the urine became sugar-free and was kept so, except for very faint traces in some individual specimens. To accomplish this permanent result and feed the patient with a comparatively liberal diet it was necessary to give about 200 units in eight injections daily for a week when decreasing doses were sufficient. Three months later the wound was healed, the urine was sugar-free without insulin with a diet containing about 80 g. protein, 120 g. fat, and 90 g. carbohydrate.

[5] Ibid., p. 99.

[6] Ibid., p. 619.

[7] Owen-Jones, R.: The Lancet, 1924, ii., 1119.

I think that this case very definitely shows that no pessimistic conclusions as to the possibility of abolishing glycosuria or normalising glycæmia in the presence of severe infection need be drawn from failures in cases in which doses not higher than 80 units in 24 hours were employed, as in Joslin's cases, or even when as much as 120 units in the same period of time were given, as in my Case 281.

As to the second point, it seems to me that Dr. Joslin's negative advice is mainly intended to emphasise the fact that extreme and prolonged underfeeding, carried out in order to render the urine sugar-free in diabetic patients suffering from severe infections, will in most cases be of no avail and may prove disastrous to the strength of the patient and to his powers of fighting the infection. This, however, is not the same thing as the above-mentioned advice as formulated: "When dealing with infections a rigorous attempt should not be made to get the patient sugar-free," since now we have in insulin the best means of fighting efficiently against hyperglycæmia and enabling us at the same time to feed the patient adequately.

My above-mentioned patient (Case 155) was kept with nearly no food for one day, then with no food for the next two, and on the fourth day, when he received only about protein 1 g., and carbohydrate 7 g., with practically no fat, and 30 units of insulin (in the four days he received a total amount of 173 units), he excreted 21·5 g. of nitrogen by the urine, corresponding to a protein destruction of about 140 g. Three days later, with 110 units of insulin, he received protein 9 g., fat 2 g., and carbohydrate 82 g., was sugar-free, and excreted only 8·4 g. of nitrogen, corresponding to a protein destruction of about 59 g. Two days later, with 80 units of insulin, the protein destruction was only about 62 g., as calculated from a nitrogen excretion in the urine of 8·9 g., despite an increase of the diet up to protein 51 g., fat 80 g., and carbohydrate 110 g., although 5·6 g. of dextrose were excreted. In my Case 218 a negative protein balance of −64 g. protein on Jan. 6th, 1924, when he received 17 g. protein, 90 g. fat, 119 g. carbohydrate, and 130 units of insulin (third day of insulin), improved to a balance of −4 g. protein on Jan. 22nd, when the patient received 23 g. protein, 205 g. fat, 61 g. carbohydrate, and 80 units insulin, there being very faint traces of glycosuria; and even further improved to a positive balance of +17 g. protein on Feb. 11th, when the patient received 45 g. protein, 165 g. fat, 80 g. carbohydrate, and 80 units insulin, without glycosuria. My successful case (403) with a carbuncle, in which it proved so difficult to free the urine from sugar, was subsequently kept sugar-free, and liberally fed all through except for the first two or three days of treatment.

It being possible in all diabetic patients, even in the presence of severe infection, to combat the hyperglycæmia without any dangerous underfeeding, the question remains: Is it necessary, in all or in some such cases, to give all this insulin and to take all measures that may be required to render the urine sugar-free or the blood-sugar level normal?

In many instances a certain decrease of the glycosuria or a certain lowering of the blood-sugar level, although not bringing about sugar freedom or normal glycæmia, suffices to change for good the course of events in cases of infection in diabetic patients that were doing very badly. But it would be wrong to conclude that under such circumstances it is never essential that glycosuria be thoroughly abolished or glycæmia be brought to normal. Some such cases do well, either from the beginning or from a given moment, even although no dietetic or other measures are taken to reduce the glycosuria, while this does not actually decrease until the local process has already begun to mend, yet nobody would advise that in all cases no effort need be made to reduce the glycosuria. The truth is that the blood-sugar level at which an infectious process may do well or cicatrisation follow its normal course is different in different cases, depending on circumstances that are, thus far, unknown to us. The possibility exists that in many cases this critical level is just at or about the normal point.

This possibility is well illustrated by Case 332, a woman with no history of diabetes, but with a very large surgical wound of the abdominal wall, which showed no tendency to heal for some weeks. Eventually a necrotic focus appeared in one part of the wound. The urine was tested for sugar and a very faint trace found. When I was called for the first time the Benedict test was negative, but the blood-sugar, three hours after the ingestion of 200 c.cm. of milk, was 0·14 per cent. I did not consider it probable that such a slight departure from the normal could have anything to do with her condition, but nevertheless put her under treatment. Rather to the surgeon's and my own astonishment, from the third day, when the blood-sugar was 0·095 per cent. under circumstances comparable to those of the previous analysis, the wound began to granulate, the necrotic area began to get cleaner, and in a remarkably short period of time the process of healing was completed.

Since the possibility exists that complete sugar freedom and even normal glycæmia may be essential for a satisfactory course of events in a diabetic patient with an infectious process, and since a normal blood-sugar level may be attained in all cases, even in the most severe (unless there is not time enough before the patient dies), with the help of insulin and with no need for undue underfeeding, it is my opinion that, when a given case of this kind is not doing quite well, every effort should be made in order to abolish glycosuria and even to attain a normal blood-sugar level by the means indicated.

The fact must be remembered—and I have found many cases in my experience—that a harmful hyperglycæmia may exist even although no traces of sugar are found in the urine. In cases that are not doing well, even when no sugar is found in the urine, it is therefore necessary to ascertain whether the blood-sugar be normal, and to render it so if it be in excess.

Summary.

From personal experience of cases of surgical infection in diabetic patients and of their treatment by insulin the following conclusions are drawn:—

1. Even in the more severe cases of infection in diabetic patients it is always possible (unless there is not enough time before the patient dies) to attain a normal blood-sugar level if insulin be used in large enough doses properly spaced throughout the day.

2. It may be difficult, or even impossible, to keep the blood-sugar level absolutely normal all the time through, but it may be kept so most of the time and not far from normal the rest of the time.

3. Such a result may be obtained without any dangerous underfeeding, which must be carefully avoided. In fact, with an adequate combination of diet and insulin such patients may be kept sugar-free and at the same time well-nourished, much better than would be possible by any other known measures, dietetic or otherwise.

4. In many cases infection in a diabetic patient may follow a favourable course even when there is a certain degree of glycosuria or hyperglycæmia, but in other instances it may be very different.

5. So long as a given case of infection in a diabetic patient, in which glycosuria or even only hyperglycæmia persists, is not doing well, all efforts must be made to render the urine sugar-free or even to attain a normal blood-sugar level, with the help of insulin and avoiding undue underfeeding.

DIVERTICULUM OF THE PHARYNX.

By J. W. THOMSON, M.B., C.M. Aberd.,
SENIOR SURGEON, CLAYTON HOSPITAL, WAKEFIELD.

Diverticula towards the upper end of the pharyngo-œsophageal tract have been variously described as pharyngeal, œsophageal, and pharyngo-œsophageal. It has been shown by Killian that the pulsion, or pressure, diverticulum is of pharyngeal origin, and consists of a protrusion of the mucous and submucous coats between the circular and oblique fibres of the crico-pharyngeus muscle in the postero-median aspect of the pharynx. Killian also points out that the transverse fibres of this muscle act as a sphincter, in the same way as does that at the cardiac extremity. Cardiospasm causes dilatation of the whole circumference. Œsophagospasm causes bulging at the weakest part of the pharynx, as the cricoid cartilage and the thyroid gland strengthen the anterior and lateral walls.

These diverticula may possibly be of congenital origin, though they have not so far been discovered in infancy or childhood. Some cases are ascribed to injury of the œsophagus; others, again, to stenosis of the first part of the œsophagus, or the cause may be extrinsic, as from pressure by a tumour. They occur mostly in adult males, and symptoms are rare before 40. The sac passes generally to the left, sometimes to the right, of the œsophagus, and may reach the mediastinum.

Clinical Record.

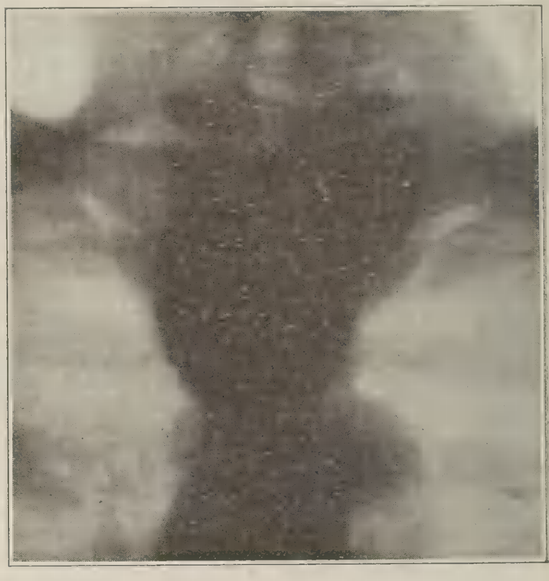
Mrs. E. J., aged 63, admitted to the Wakefield Hospital on April 11th, 1924. For 14 or 15 years she had difficulty in swallowing, but when younger she could overcome this difficulty. The condition gradually grew worse, but not until two years ago did she consult a doctor. It was suspected that she was suffering from a diverticulum of the pharynx, and this was confirmed by X ray examination. The barium meal was seen to fill the pouch and then overflow into the œsophagus. The diverticulum was not palpable. Operation was refused and she left the hospital.

Five months later she was readmitted. She had spent those months in a constant vain endeavour to satisfy the cravings of hunger by filling the pouch with food, when some would probably overflow into the œsophagus. The contents of the sac were then regurgitated, and this process was repeated over and over again. Such articles as peas and currants would remain in the pouch for about a week. The frequent filling up of the pouch with saliva added to her misery and disturbed her sleep. Worn to a shadow (her weight, at one time 15 st., was now about 6 st. 10 lb.), scourged with bed-sores, distraught with a gnawing hunger and a torturing thirst, she was in imminent danger of death from starvation.

Immediate removal of the pouch was out of the question, therefore gastrostomy under local anæsthesia was performed. She continued to eject the contents of the sac for a day or two after the operation. Recovery was rapid, and she was able to be up in a chair in a fortnight. In five weeks it was considered that she was fit to have the diverticulum removed. The various methods of performing the operation were considered—e.g.; the two-stage operation, invagination and diverticulopexy. Further X ray examination was carried out, and the sac seemed longer and narrower. The examination was more difficult, as the barium meal was frequently regurgitated before it completely filled the sac.

Operation.—Chloroform was administered, preceded by morphine and hyoscine. Local anæsthesia would have been eminently suitable and perhaps preferable. An incision was made along the anterior border of the left sterno-mastoid. The depressors of the hyoid and the sterno-mastoid were separated; the omohyoid was divided, the trachea and thyroid were retracted inwards, and the sac was at once exposed, lying between the pretracheal and prevertebral layers of the cervical fascia, and passing into the posterior mediastinum. It was not difficult to separate it from those layers of fascia, though at its base one or two fibrous adhesions were divided. Some muscle-fibres were seen to run over the neck of the sac in a vertical direction. Its length was 3½ inches, its width 1 inch. The opening into the œsophagus was wide, and digital examination revealed no stricture. The sac was clamped and divided and sutured, after the manner of Mayo's operation for umbilical hernia. When released from the clamp it disappeared behind the pharynx. It seems, therefore, that if on division it was allowed to escape from the clamp it would be difficult to recover, and dangerous sepsis might ensue. A small tube was inserted, which was removed in 36 hours, and about this time fluid was given by the mouth. Swallowing was difficult and painful at first, but re-education of the mechanism of deglutition was almost complete in a week, about which time she was got out of bed. The wound healed well, no sinus formed, and no bougie was passed at any time. It is important that the proximal end of the diverticulum should be clamped before elevation or manipulation of the sac should disturb its contents, which might otherwise be aspirated into the lung.

If the condition was due to spasm, when did the spasm pass away? Did it disappear when it had formed a pouch, or did it pass away during the five weeks' rest following the gastrostomy, or did the removal of the sac cause it to disappear? One may wonder, too, how a sac without, or with deficient, muscular tissue in its walls can so readily empty itself.



Showing diverticulum of pharynx.

(Radiogram by Dr. J. Alexander Thomson.)

Pathological Report by Dr. P. L. Sutherland, *Pathologist to the Wakefield Hospital.*—"Microscopic examination of sections of the diverticulum shows that it is composed of a layer of epithelium surrounded by loose areolar tissue containing scanty and irregular muscle bundles arranged both longitudinally and circularly. The epithelium, which occupies from one-quarter to one-third of the total thickness of the wall, is formed of from 15 to 20 layers of stratified cells, and is very much folded. The muscle-fibres do not form continuous circular and longitudinal layers, but occur as irregular bundles arranged close to the epithelial lining. Beyond the muscle-fibres there is a layer of loose areolar tissue, containing large numbers of blood-vessels and small clumps of lymphoid tissue. Glands are present, but are very small and scanty. The epithelial lining of the diverticulum is thicker than normal, and the muscular coat is defective, and there is no orderly arrangement of the coats into muscularis mucosæ, areolar tissue, and muscle bundles."

The patient is now in good health, has no difficulty in swallowing, and is gaining in weight.

PS.—Since writing the above I learn that food is occasionally ejected forcibly through the mouth and nose, as if there were some continuance or recurrence of the spasm. Further X ray examination (April, 1925), however, showed no delay in the passage of food, and no narrowing at the site of operation. There is a steady gain in weight.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SUB-SECTION OF PROCTOLOGY (SECTION OF SURGERY).

X RAY DIAGNOSIS OF COLON DISEASE.

A MEETING of this Sub-section took place on May 13th, Mr. F. SWINFORD EDWARDS, the President, being in the chair, when a discussion took place on the Value of X Rays in the Diagnosis of Diseases of the Colon.

Dr. GILBERT SCOTT, in opening, said this subject was equally important to the surgeon and the radiologist, and he did not think the radiology of the colon had been developed to an equal extent to that of the stomach, perhaps because most surgeons felt that they had not derived full diagnostic value from the method, and hence they ceased to send to the radiologist the material they otherwise might. The value of this diagnostic means could be greatly enhanced if surgeons would (1) supply material to the radiologist, (2) keep the latter informed as to results, especially as to failures, and particularly in private cases. Dr. Scott said he feared that too much was expected of the radiologist; if he overlooked a lesion, or committed a diagnostic error, it was common for the whole examination to be regarded as discredited. The radiologist was working under difficulties, and it must be remembered that patients' interiors varied as much as did their exteriors within normality. At London Hospital every gastric case was given an opaque meal examination, as it was of considerable diagnostic value in such cases, and large series of radiograms enabled the worker in this field to see the error of his ways.

The value of the method depended on (1) correct technique, and (2) correct interpretation. He regarded the opaque enema as of the same value for colon disease as was the meal for stomach cases. In the former, by the time an opaque meal reached the lower part of the gut it was so broken up and haustration was so marked that at the end of the tedious examination one was left in doubt whether or not an organic lesion was present. Hence, for colon cases, or cases in which the colon was suspected to be diseased, he had for some time discarded the barium meal for the opaque enema. He would, therefore, in this discussion, deal with that method by which the whole of the large gut could be visualised. The gut could be manipulated under the screen, and an expert could complete the examination in half an hour without discomfort to the patient. He emphasised the importance of a careful preparation of the patient, as fæces in the colon might lead to errors in diagnosis.

If the technique was correct, the most difficult part remained—namely, the correct interpretation of what was visualised. There were two kinds of error of interpretation: (1) passing a lesion undetected, (2) diagnosing by the rays a lesion which was not found at operation, the second being far the more common. Fæces in the colon, air-locks, pressure from without, spasms, or a partially filled gut might all be reported as organic lesions. The most difficult cases were those with small and atypical lesions. It was almost impossible by this means to differentiate between tubercle and new growth.

Dr. Scott narrated and illustrated a series of examples to elucidate his subject, remarking that at the Mayo Clinic the lesion diagnosed by the rays was found at operation in 91 per cent. of the cases, the lesion not having been demonstrated in the remaining 9 per cent. He thought a serious effort should be made to bring this country abreast of other countries in the matter of a thorough study of the normal appearances; at present there was too great a tendency to regard any deviation from what was considered normal as necessarily pathological. There was also, with us, a distinct lack of collaboration between the surgeon and the radiologist.

Mr. HAMILTON DRUMMOND said his interest in this method of diagnosis was of some duration, but his earlier optimism had been mellowed by subsequent experience, though he still regarded radiology as an important means of diagnosis. Pitfalls were numerous, and considerable experience was needed before being able to estimate the value of the rays in this regard. The only way to palpate the colon was to use both the fingers and the sight, securing a concentration of both faculties. During the last five years he had been his own radiologist for his colon cases. He felt that if the surgeon was to have the full benefit of radiology he should furnish to his X ray colleague a full history of the case, or, preferably, meet him in consultation over the patient. Sometimes patients were sent to the X ray department before a thorough clinical examination had been made; this latter should include the use of the sigmoidoscope. The question might be asked whether one was justified in basing a diagnosis of malignant disease of the colon on the results of X ray examination alone, and he would answer that X ray examination of the colon by barium meal or opaque enema was seldom a prime factor in diagnosis; symptoms and history furnished information of the greatest diagnostic value, though X rays might assist in determining the site of the disease. He had seen patients with growth in the hepatic flexure, with considerable stenosis, in whom a barium meal passed through the colon beyond the growth without delay. There might be a similar happening in the case of a tight stricture of the ileum. X rays were of great value in the diagnosis of such conditions as a pelvic cæcum, a V-shaped transverse colon, and various kinks in the lower ileum and pelvic colon.

Dr. BERTRAM SHIRES said that for many years he had carried out the two methods of examination in colon cases, and in the majority the enema was of the greater value. Unless, however, the radiologist and surgeon worked hand in hand there were many traps which they were liable to fall into. In 30 per cent. of cases in which the barium enema was given there was a filling defect in the pelvic colon in the early stages. In one case in which there was a filling defect in the pelvic colon a study of the clinical aspect and the skiagram led to the diagnosis of carcinoma being made, but abdominal section revealed nothing more than a slight spasm at the lower end of the descending colon. One case appeared to be diverticulitis, but at the operation it was found to be generalised tuberculosis of the abdomen, with a mass in the pelvic colon.

Dr. ARTHUR F. HURST said the chief interest of the subject consisted in how far X rays helped in the early diagnosis of organic disease of the colon, and this interest would be stimulated by a comparison of different methods of examination. Recently he had had the benefit of team work. Chemical examination for occult blood after the patient had been carefully prepared by a hæmoglobin-free diet he had found to be of the greatest value of all, as he and his colleagues had never had a case of growth of the colon in which occult blood was absent. For conditions in the last 10 inches of bowel the sigmoidoscope was of great value, as it gave direct vision, but there were cases in which one was in doubt, and in these barium was a help. He considered that if there was a clinical history pointing to the possible presence of a growth, with constant occult blood, operation should be done, in spite of a negative X ray result. He showed skiagrams of a number of instructive cases.

Dr. ULYSSES WILLIAMS agreed that the barium meal was practically useless to show the position of disease in the colon, but an opaque enema was very useful. For revealing the appendix the meal should be made with buttermilk. He thought the operation of colopexy should be allowed to fall into oblivion. It did not matter where the colon was, as its position had no influence on the question of obstruction.

With regard to the normal position of the hepatic flexure, most books said it was at the tip of the eleventh costal cartilage, but in over 75 per cent. of normal healthy people he had found it to be, with the persons standing up, just at the crest of the ilium.

Mr. J. P. **LOCKHART-MUMMERY** spoke of the great improvement which had taken place in the diagnosis of colon disease in the last 12 years. An important question was as to how carcinoma of the colon was to be diagnosed when there was neither a palpable tumour nor obstruction; this was now accomplished in many cases in which neither of those helps was present. If diagnosed early, there were no more satisfactory operations for carcinoma than on those growths in the colon. He placed a higher value on the sigmoidoscope than did Dr. Hurst; if a patient had been properly prepared, his experience was that in the majority of cancer cases blood, or traces of it, could be found high up in the sigmoid, if there was no such condition as ulcerative colitis. He attached considerable importance to the history. X rays were a distinct help in the localisation of the growth, and he thought there would be increased accuracy in this in the future. Negative X ray evidence was useless. It was very important to repeat the opaque enema, to lessen the chance of error. By this means also diverticulitis could be either confirmed or excluded, a very important advance in the diagnosis of colon conditions.

Dr. W. H. **COLDWELL** considered that there was still much to be said in favour of the barium meal as a diagnostic aid in conjunction with the opaque enema in colon conditions, though the enema was the more valuable. He had a word to say about the inefficiency of some wash-outs before making an X ray examination, and the errors which the shadow of fæces left behind might give rise to. For detecting diverticulitis, of which he threw some skiagrams on the screen, he thought the opaque meal was as useful as the enema, and most patients preferred the meal, owing to its greater convenience.

Dr. S. C. **SHANKS**, speaking of the barium enema method, pointed out that there were certain "silent areas." The first was in the sigmoid. One loop of the sigmoid might be superimposed on another loop, and in that way the symptoms might be obscured. Another silent area was in the splenic flexure. And in the middle of the transverse colon there was often an area which an enema did not fill; it was the highest part, and the enema fell to the more dependent portions. Thus the part which looped over the ridge formed by the spinal column was not filled. He had seen such cases in which the skiagraphic picture resembled that of carcinoma. The barium-meal method was very valuable for investigating cases of chronic constipation; a large mass in the rectum settled the question. In 196 examinations he had made by barium enemata, he found 14 definite cases of diverticulitis (or 7 per cent.) and five doubtful ones. On separating hospital from private cases he found that in the former out of 150 examinations there were three cases of diverticulitis, or 2 per cent., while in 46 examinations of private patients there were 11 of diverticulitis, 24 per cent. That seemed to show that well-to-do people were more prone than others to this condition.

Mr. **ASLETT BALDWIN** related a case in which a man said he felt some inconvenience in the left side of the abdomen, and had some trouble with defæcation. Examination with the sigmoidoscope did not disclose blood or mucus, and the X ray report was that there was no filling defect nor obstruction. The man was put upon paraffin, with hopes for the best. Six weeks later he said he felt certain there was something abnormal present. Mr. Baldwin thought he could feel a lump, and some distension of the large intestine. He operated, and found a carcinoma in that situation. Another case he described was that of a man who had constipation for a week and had been treated with enemas. When seen, he complained of pain in the upper part of the abdomen on the left side, which was tender. A large mass could be felt on the right side of the abdomen. Washing out was done for a week, bringing away large flakes of lymph and mucus, and the sigmoidoscope showed streaks of blood. X ray examination showed the large intestine and transverse colon down in the pelvis, forming a very acute kink on the left side, and another on the right. There was no sign of any filling defect. The man was told to continue with paraffin, and though that was 14 years ago there was nothing further to report.

LONDON ASSOCIATION OF THE MEDICAL WOMEN'S FEDERATION.

A MEETING of this Association was held on May 8th, at the London School of Medicine for Women, to entertain the council members of the Medical Women's Federation. Demonstrations were given by various members of the staff of the School. In the physiology department Prof. Winifred Cullis demonstrated on the isolated mammalian heart, the action of certain drugs, and the production of arrhythmia by section of the A.-V. bundle. Miss M. Bond, M.Sc., communicated the results of her feeding experiments as to the content of vitamin A in bacon-fat, experiments undertaken in view of the fact that this fat is largely used in the dietary of children. Miss D. Woodman, M.Sc., showed slides, indicating that the feeding of rats with parathyroid exerts an inhibitory action on the thyroid. Mrs. Pillman Williams, M.B., demonstrated the methods of blood-group determinations. Microscopic preparations of fœtal tissues, demonstrated by Prof. M. F. Lucas Keene and Miss E. E. Hewer, D.Sc., were set out. These illustrated some of the points that have emerged in the course of their investigations regarding the correlation between the structural changes in the organs of the fœtus with physiological activity. Miss M. Waller, B.Sc., demonstrated emotive response to stimulation.

A demonstration was given by the National Institute of Industrial Psychology on various applications of psychological tests. Examples were shown of the best known varieties of both linguistic and performance—i.e., non-linguistic—intelligence tests. Some of the tests which are being used for vocational guidance and selection were also demonstrated. Specimens were shown of tests for the selection of engineers, weavers, clerks, and packers, all of which tests had been devised by the Institute at the request of various industrial firms. Some examples were on view of general tests for "manual dexterity" and "mechanical ability" which are being used in connexion with research into the best methods of vocational guidance.

The meeting was largely attended, over 150 members being present.

BRIGHTON AND SUSSEX MEDICO-CHIRURGICAL SOCIETY.

A MEETING of this Society was held on May 7th, Dr. E. F. **MAYNARD**, the President, being in the chair, when Mr. M. **FITZMAURICE-KELLY** read a paper on

Some Abdominal Emergencies in Children.

He remarked that the mortality associated with these conditions was to a great degree preventable, and that improvement in results was to be looked for mainly in the direction of earlier diagnosis and treatment. Dealing first with appendicitis, attention was called to the fact that, early in the attack, pain was often not localised, but was complained of across the abdomen. The importance of a band of hyperæsthesia above Poupart's ligament, as evidence that perforation had not yet taken place, and the information to be derived from rectal examination, were especially emphasised. Treatment consisted in immediate operation, delay being dangerous in young children. The right paramedian incision with internal displacement of the rectus was preferred in most cases; in those with definite localisation to the right iliac fossa, Mr. Fitzmaurice-Kelly preferred Battle's incision, closing it again with drainage of the rectus sheath and providing stab-drainage elsewhere if necessary. In the matter of drainage the surgeon was guided chiefly by his judgment in the individual case as to whether the peritoneum was capable of dealing with the exudate, but as a general rule drainage was more frequently required in diffuse peritonitis in children than in adults. In post-operative ileus the value of pituitary extract and eserine, in combination, was mentioned—in the worst cases jejunostomy was the only hope and should not be unduly delayed. Acute inflammation of Meckel's diverticulum was briefly mentioned, and the value of a paramedian incision in dealing with it pointed out. Pneumococcal peritonitis was not very rare among young girls of the poorer class. Many cases were mistaken for appendicitis; suggestive symptoms were the onset with symptoms of pelvic irritation—loose stools, painful and frequent micturition—and in acute cases severe toxæmia, with disproportionate increase of the respiration-rate. The acute cases did best with drainage, and the value of blood transfusion, as recommended by Fraser and McCartney, was mentioned. Referring to intussusception, Mr. Fitzmaurice-Kelly laid stress on the extreme gravity of the condition and the serious mortality—about 30 per cent.—associated with it. This was almost entirely due to a failure to recognise the urgency of the case at the outset. The clinical picture was very definite and strikingly uniform, and it was a serious error to delay treatment because a tumour could not be felt, or no blood was passed when the symptoms were otherwise suggestive. Three recent fatal cases were detailed, illustrating the sources and the dangers of delay. Pyloric stenosis in infants was, in the light of recent improvements in technique, claimed as a surgical emergency. The early diagnosis, and especially the differentiation of stenosis from pylorospasm, was discussed and Rammstedt's operation was described. In view of the fact that the mortality of cases operated on by this method was of the order of 30 per cent. against 80 per cent. in those treated medically, Mr. Fitzmaurice-Kelly contended that surgery should be invoked at the earliest possible moment after the diagnosis was definitely established.

Discussion and Reply.

The PRESIDENT recalled the days when appendicitis was a battle-ground between the physician and the surgeon. While conceding that the results were now better, he did not think that, as a result of surgical experience, we had advanced in certainty of diagnosis. He agreed that in pyloric stenosis in infants operation should be the rule.

Mr. L. A. PARRY recalled a case of intussusception in which pain had been absent throughout and the symptoms were otherwise obscure. He did not find cutaneous hyperæsthesia of much value in practice, and regarded the physical signs of rigidity and tenderness on pressure as of more value than symptoms. He called attention to the difficulty of diagnosis between appendicitis and certain cases of ileo-cæcal tuberculosis, and was strongly in favour of immediate operation in appendicitis in children.

Mr. H. NETHERSOLE FLETCHER called attention to the virulence of cases of appendicitis starting with diarrhœa. In the matter of drainage he thought no risk should be taken, and that in cases of doubt a tube should be left in. He discussed the diagnosis of intussusception from gastro-intestinal catarrh with bloody stools in infants, and emphasised particularly the intermittency of the symptoms in the former.

Dr. H. M. GALT stated in regard to blood transfusion that, in such cases as he had tested, he had always found the blood of a parent and child compatible—but he recommended that the bloods should be tested in every case.

Mr. J. R. GRIFFITH advocated a transverse incision outside the linea semilunaris, splitting the rectum sheath if more room were required, in cases of acute appendicitis. He mentioned a case of intestinal obstruction by a band following operation by the paramedian incision.

Mr. FITZMAURICE-KELLY, in reply, agreed that the diagnosis of appendicitis had not grown more exact, but contended that, in the presence of acute symptoms, an early exploration was the safest course, and the attempt to arrive at certitude might lead to a fatal delay. The same argument applied, with even greater force, to the case of intussusception, and he had never seen any harm come of a negative exploration.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

A MEETING of this Society was held on May 6th, Sir DAVID WALLACE, the President, being in the chair.

A communication was read by Dr. J. STEWART FOWLER on

Erythrœdema.

Erythrœdema, he said, also known as the pink disease and in America as acrodynia, was a rare affection of infancy and early childhood. He had seen only four cases, but doubtless as the condition became better known it would be found more frequently. The symptoms were disconnected and cases might well be overlooked. The disease appeared to be more common in Australia and was originally described and named by Swift in 1911; later Jeffreys Wood, of Melbourne, published a further series of cases. Following on this the disease was described in America by Bilderback and Weston, who called it acrodynia, and shortly after Byfield reported it under the title of "a polyneuritic syndrome resembling pellagra acrodynia in very young children." In 1922 a few cases were recorded in England by Thursfield, Parkes Weber, and Patterson, while Feer, of Zurich, unaware that the disease had already been described, gave what is the most plausible explanation of the pathology when he named it "a peculiar neurosis of the vegetative nervous system in very young children." He also demonstrated the high blood pressure in the disease.

Dr. Fowler gave a description of four cases. All of these had been perfectly healthy up to the time of the onset of the disease and no hint to throw any light on the cause could be obtained.

The first case was of a girl, aged 2, who suddenly had an attack of feverishness with vomiting. Subsequently she had become cross and sleepless and had developed an itchy rash all over the body; the fingers and toes had become thickened, red and clammy. She was wasted, could not walk, and fell forward on her face when sitting in bed. On admission the child, who was very unhappy, was moderately nourished; the cheeks and nose were bright red. She lay with her face buried in a pillow and over her body were scattered patches of punctate erythema resembling a sweat rash. The hands and feet were swollen and livid red with thickened fingers and toes covered with sodden desquamated skin with a clammy feeling. They did not pit on pressure and the discoloration reached to an ill-defined margin just above the wrist. There was a leucocytosis of 12,000. An interesting point was great muscular hypotonia without any paralysis, the knee-jerks were diminished and sensibility to pin-pricks impaired, sleeplessness was a very prominent symptom, the appetite was poor and the child wasted; there was a good deal of cutaneous irritation, especially of the scalp, with the consequence that lumps of hair were pulled out. The temperature was not raised, but the pulse was always rapid, running from 120 to 150; the blood pressure was from 100 to 120. Soon after admission some teeth dropped out without previous change in the gums, but followed by a persistent stomatitis. After eight weeks in hospital she developed first an infection of a finger-nail and later a fatal general septicæmia.

The second case, similar to the first, occurred in a boy, aged 2, who was sent into hospital by his doctor on account of stomatitis and loss of teeth. The patient was markedly irritable, but sleeplessness was not a prominent symptom. The hands and feet were the same as in the last case, as also was the irritable skin rash with consequent loss of hair. The patient died a few hours after admission.

The third case was in a female infant of 1 year. The condition had been preceded by constipation and diarrhœa six weeks earlier. The same symptoms were present in this case as in the first, but were less severe in degree. The patient improved under treatment but was taken from hospital after five weeks by her parents, who were leaving the town.

The fourth case, in a boy of 13 months, was much more rapid than the previous cases. Three months before he came under medical care he had developed bright red rashes over the body and had become limp, but was not fretful, his nose and cheeks were red and his hands and feet red and swollen. His mother was in no way alarmed. Suddenly a rise of temperature ensued and death occurred in two days. The patient presented all the appearances of erythrœdema.

Summarising the condition, Dr. Fowler said that the age of those affected was usually from 9 months to 2 years, both sexes being equally liable. The disease usually lasted a year and did not tend to be fatal. Symptoms, in their order of diagnostic importance, were as follows: The hands and feet up to the wrists and ankles were first cold, dusky red, and swollen, later the skin desquamated and secondary septic infection was liable to occur. Profuse sweating was invariable with associated rashes of an itchy nature causing the child to scratch and pull its hair. The patients were thoroughly miserable; this was evidently part of the condition and not due entirely to the insomnia which was always present. The physiognomy was characteristic, the red nose and cheeks and the mouth gaping slightly from muscular atony. Loss of teeth was common and consequent persistent ulceration of the gums. Muscular atony was the chief nervous symptom and often was the first thing that drew the parent's attention to the disease. The rapid pulse without pyrexia and the high blood pressure were probably constant features. Anorexia and salivation were features of the condition and there might be albuminuria and pyuria. Nothing definite was known as to the cause or nature of the disease. A distant resemblance to pellagra had suggested a deficiency disease, but this, the speaker held, seemed unlikely. The evidence of its being an infective polyneuritis was faulty. Another suggestion was that it might be some upset of the vegetative nervous system, and many of the symptoms might be accounted for on this hypothesis.

Treatment was not satisfactory and should be directed to maintaining the nutrition in spite of the anorexia to prevent secondary infection, especially of the mouth, and to allay the itching by dusting powders. In one case large doses of atropine were given by Feer with benefit and calcium lactate in another.

Discussion.

Dr. JOHN THOMSON quoted two cases of the condition which were remarkable in that they both were seen within ten days and came from the same small town.

Dr. CRANSTON LOW suggested that the primary condition might lie in septic absorption from the teeth. He thought that the condition of the hands and feet might be considered as exaggerated chilblains.

Dr. FOWLER, in reply, said his four cases came from different places. He thought there might be a possible relationship to chilblains in the condition of the extremities, but he did not think the condition of the teeth primary as in his cases the condition was well established before the teeth became loose.

Dr. CHARLES MCNEIL read a communication on

Fibrosis of the Bronchi and Lungs in Childhood Following Broncho-Pneumonia.

When fibrosis had become established, he said, cough was a definite feature. In his cases cough was very troublesome in the morning on waking, lasting from half to one hour and leaving the child with little appetite for breakfast. Coughing also might occur during the night, waking the child. Cough also occurred on exertion, and vomiting frequently followed a paroxysm. Expectoration was not copious nor fœtid and in no case contained tubercle bacilli. Apart from the paroxysms, there was a clearing of the throat, but this was not characteristic. Breathing was easy with occasional wheezing. The fibrosis was unilateral and usually left-sided with flattening on the affected side and loss of expansion. Dullness was found on percussion, but if extreme suggested pleural thickening or effusion, on auscultation the breathing was bronchial and might be faint or loud, it might become low-pitched, and always did so if bronchial dilatation occurred. Adventitious sounds were the rule and varied with the cough. Radiograms confirmed the physical findings with a uniform shadow on the affected side. Displacement of the heart could readily be seen. Bronchiectasis occurred in some cases, giving characteristic signs. Displacement of the heart was a cardinal sign in unilateral cases. The diaphragm also was pulled up with corresponding alteration of abdominal viscera. The standard of general health in the speaker's cases had been good; though exacerbations of cough had interfered with nutrition in some patients they had been rather prone to extension of pulmonary catarrh. Infectious diseases of childhood were borne well by the children. With regard to tuberculosis, Dr. McNeil said that in older descriptions confusion existed between fibrosis and fibroid tubercle, but after the discovery of the bacillus this had no longer troubled observers. He himself did not think that children suffering from fibrosis were any more prone to tuberculous infection than healthy children. Syphilis was excluded as a cause of fibrosis in the cases quoted. Certain cases showed marked symptoms, but without definite physical signs. X rays showed that the lungs were not quite clear, the change being bilateral. The symptoms in these cases were often very severe and the malnutrition marked.

A description of the pathology of the condition was given, emphasis being laid on the site in the lung where the interstitial inflammation began. Advanced fibrosis of the lungs with or without bronchiectasis was compatible not merely with survival to adult life, but even to old age with a fairly active working life. Ordinarily the prognosis was good, but absence of albuminuria and circulatory disturbance were to be looked on as reassuring signs. The disease did not appear to progress or retrogress with advancing age. Treatment was directed towards alleviating the bronchial catarrh and consequent cough, and an attempt was made to resolve the fibrosis. The patient was kept in bed with plenty of fresh air and sunshine, which caused the cough to abate quickly. Iodides and thyroid had been given but without definite results. Other symptoms are treated on appropriate lines. Case notes of six cases of definite unilateral cases and 12 incomplete cases were included, and the communication was illustrated by X rays and coloured photographs of complete lung sections.

Discussion and Reply.

Dr. FOWLER suggested that the condition was largely pleural and quoted a case of his own which originated in a comparatively trifling pleural effusion. The pleura thickened and the characteristic symptoms developed. The X ray appearances could be accounted for in this way.

Dr. W. T. RITCHIE referred to cases seen by him and spoke of the X ray appearance as a means of diagnosis from pulmonary tuberculosis.

Mr. D. GUTHRIE spoke of cases exactly as described being caused by a foreign body. He had been on the look-out for such a case, but did not think it as common as was supposed, nevertheless the X rays should be examined from this point of view.

Dr. G. D. MATHEWSON mentioned an aortic systolic murmur in a case examined by him which he thought due to mechanical action on the root vessels in the neck.

Dr. MCNEIL, in reply, said he thought that though in many cases the change might be pleural, in others the change was undoubtedly in the lung. The X ray showed more than the percussing finger could detect as the change lay deeply at the root of the lung. The diagnosis from tuberculosis was often difficult, especially in slight cases. A cutaneous tuberculin test was often helpful, as also was examination for the bacillus. He had not detected a foreign body, but it was possible that one might be masked in the denser shadows. In none of his cases had an aortic murmur been heard.

Mr. J. W. STRUTHERS showed a clinical case of

Endothelioma of the Dura Mater.

This case had been shown to the Society two years previously when an attempt had been made to remove the tumour. The attempt had not been successful, but had caused a disappearance of symptoms for a year, after which there was a return of symptoms. The patient was admitted to hospital recently, complaining of pain in the forehead. There was no sign of increased intracranial pressure. The tumour was removed and was peculiar in that, though small, it projected very little from the surface of the dura, but had the property of eating its way into the overlying bone. Prognosis was not good. Although a simple tumour in its original stages, there were considerable difficulties in removal, and it was likely to recur and spread along the base of the skull. Several microscopical preparations were shown.

Dr. HARVEY CUSHING (Boston, Mass.), Sir EDWARD SHARPEY-SCHAFER (Edinburgh), and Sir CHARLES SCOTT SHERRINGTON (Oxford) were elected honorary members of the Society. Prof. HENNING RONNE (Copenhagen) and Sir WILLIAM BOOG LEISHMAN were elected corresponding members.

ABERDEEN MEDICO-CHIRURGICAL SOCIETY.

AT a recent meeting of this Society, with Dr. JAMES CROMBIE, the Vice-President, in the chair, Mr. G. S. DAVIDSON read a paper on three cases of

Neonatal Hæmorrhage,

due to some of the rare causes. The first was an infant who was delivered by forceps and showed two bruises on the head caused by the pelvic outlet; these showed much clot, which was slow to form and adhered poorly to the scar. Circumcision was necessary on the third day after birth, and was followed by alarming hæmorrhage in the form of general oozing, which was finally arrested by the cautery. Recovery was uneventful, and it was considered that the child was a bleeder, though it was not possible to estimate the coagulation-time or the fragility of the clot. The second case was one of an infant who on the day after birth developed marked jaundice and on the next day intractable vomiting, at first curdled milk, and later bright red blood. In spite of treatment by rectal salines and intramuscular injection of serum the child died on the following day, and, post mortem, no possible source of the hæmorrhage could be discovered. Was this another bleeder? The third case was one of a feeble infant who died on the fourth day after birth as a result of hæmorrhage from the bowel. Here an abdominal tumour could be palpated and was diagnosed as an intussusception, but the child was too ill to permit operation. Post mortem, a spherical cyst of 3½ inches in diameter was found lying between the layers of the mesentery in its upper part, with a loop of bowel stretched tightly over it. Microscopic examination of the cyst wall showed it to be composed of a double layer of unstriped muscle lined on the outside by a thin layer of peritoneum, and on the inside by a mucous membrane resembling that of the neighbouring bowel, but somewhat atrophic. No communication was found between the lumen of the bowel and the cyst cavity.

This condition in such a young infant, Mr. Davidson said, was extremely rare. Well over 200 cases of mesenteric cyst had been reported, but of these only a few occurred in infants. He discussed the condition generally, and suggested a new classification:—

1. *False* (usually some history of trauma; walls of fibrous tissue with small round-celled infiltration, and with no epithelial lining).—(*a*) Serous; (*b*) chylous; (*c*) blood; (*d*) purulent; and (*e*) cystic malignant disease.

2. *True* (with an epithelial lining, unless a pressure atrophy has set in and obliterated it).—(*a*) Dermoid; (*b*) hydatid; (*c*) intestinal sequestrations: (1) mesenteric, (2) antimesenteric (Meckel's diverticulum), and (*d*) retroperitoneal sequestrations (usually Wolffian). Any of these true cysts might be complicated by a discharge into them of serum, chyle, blood, or pus.

At the same meeting Dr. EDWARD R. C. WALKER gave a paper on Pædiatric Experiences in America, in which he described the places he had visited and the work which had appealed to him during six months' post-graduate study in the United States.

Reports and Analytical Records.

ÆTHER PURISS, B.D.H.

(THE BRITISH DRUG HOUSES, LTD., CITY-ROAD, N. 1.)

THIS preparation is offered as a new and distinctive quality of absolute ethyl ether. We recently analysed a sample and reported a trace of peroxide, all other possible impurities being absent. A new sample was then sent to us when we found no reaction of peroxide, the preparation being a very pure form of ether. On inquiry it was ascertained that the first sample had been in our hands for six months, and, being overlooked, had received no protection against exposure to light or percolation of air through the cork. The new sample of ether gave no reaction for peroxide: it is an absolutely pure product.

"TABLOID" HEXAMINE AND METHYLENE-BLUE.

(BURROUGHS, WELLCOME AND CO., SNOW HILL BUILDINGS, LONDON, E.C. 1.)

This is a combination of 3 gr. of hexamine with ¼ gr. of methylene-blue. The therapeutic activity of hexamine is enhanced by the addition of methylene-blue, which possesses analgesic as well as antiseptic properties and is equally active in acid or alkaline urine. The combined product should be of value in a variety of biliary and genito-urinary conditions, before and after operations on the kidneys and prostate, in pyelitis, urethritis, and septic urinary conditions. "Tabloid" hexamine and methylene-blue is sugar-coated and the ingredients are, it need not be said, of a high standard of purity and reliability. The drug is issued in bottles of 25 and 100.

LANSOLETTES.

(MESSRS. ROBERTS AND CO., 76, NEW BOND-STREET, W.1.)

The conditions in which a non-irritating laxative is required are very prevalent, while it is notorious that the public abuse their internal economy by experiments in purgation. Liquid paraffin as a therapeutic agent has therefore to recommend it the facts that it is quite efficacious in suitable cases and does no harm by the establishment of an irritating habit. It is not everybody who might be benefited by taking liquid paraffin who finds the remedy agreeable, though there are on the market now brands that are practically tasteless. Messrs. Roberts and Co. have devised a combination of paraffin with agar-agar, and have made up tablets of this material containing 30 per cent. of lansoyl, a liquid paraffin with agar-agar in a chocolate basis. Thus an agreeable method of administering paraffin, especially to children, is provided, for it would take an expert to detect the presence of the lansoyl through the chocolate. The tablets, called lansolettes, are made up in boxes of 12, the adult dose being one or two tablets with or after the principal meals, the dosage for children being suitably reduced.

Reviews and Notices of Books.

Lamarck-Darwinism and Dental Disease.

By Oran Starr, D.D.S., L.D.S. London: G. Routledge and Sons. 1925. Pp. 319. 21*s.*

A large part of this book is taken up with an elaborate study of the general principles of evolution. The author puts forward views which do not accord with much of the usual biological teaching in this country and attempts to show that dental disease cannot be explained except by regarding it as due to an infraction of those biological principles which, in his view, have governed the evolution of species. The prevention of dental disease can only become possible if we return to the function and environment of our primitive ancestors who were relatively free from caries of the teeth and pyorrhœa.

The author is a firm believer in the views of Lamarck that acquired characteristics are transmissible, and his argument completely depends on acceptance of this hypothesis. While he recognises the part played by natural selection, he considers that variations are purposeful and not haphazard. In his view evolution depends on an alteration in function induced by a gradual change in environment and represents an attempt of the organism to adapt itself to its surroundings. A teleological factor is thus implied though not specifically stated. This change in function precedes anatomical variation. Since the variations are transmitted they grow in snowball fashion and lead to the formation of new species. This is no new conception. The Neo-Lamarckian school has many adherents, but we imagine that there are few who would state the problem in terms so precise and emphatic as the author. Even those who believe that acquired tendencies may be inherited, would state their case in a way very different from Lamarck and would be far from accepting the views put forward in the famous "Philosophie Zoologique." Mr. Starr, however, is *plus royaliste que le roi*, and is fully prepared to accept the whole story, giraffe, wading birds, and all. To him "Lamarck-Darwinism" is more than an hypothesis; it is a gospel with infinite applications to the whole of life. In this volume he has used it to explain dental disease. But equally, his preliminary treatise on evolution might be an introduction to, and an explanation of, almost any form of vital activity, whether mental or physical. Indeed, if we mistake not, the author would regard the laws which he has framed as being not only an explanation of evolution, but also a new instrument of thought capable of wide application. Perhaps we have here the first instalment of a new synthetic philosophy. Mr. Starr postulates that the changes in any organism as well as the changes in environment must be gradual. He regards these as conditions so essential that they assume for him the sanctity of inviolable laws. Dental disease is due to infraction of these laws. Man's dental downfall began with the introduction of fire for cooking, for at once this introduced a sudden change in environment. The teeth being deprived of their birthright of vigorous mastication, became degenerate structures increasingly less able to resist disease as time went on. If we wish to recover our dental health we must revert to raw food, preferably of a vegetable character. Since man in his evolution did not pass through a flesh-eating stage, meat should not be eaten. Fish, however, is permissible, for man, like other mammals, passed through a piscine stage in which many fish were predatory and lived on other fish. To eat fish, therefore, is not a violation of natural law, since it is part of our natural dietetic heritage.

There is undoubtedly a germ of truth in the author's contention that there is an evolutionary factor in dental disease, and that the jaws and teeth are suffering from a gradual degeneration consequent on their relative disuse as compared with primitive man. It is conceivable that an alteration in our environment, which imposed a hard, detergent, and non-fermenting food in place of the soft, starchy aliment of the modern Englishman, might, in the course of time, bring back the massive jaws and strong teeth which the primitive savage even to-day possesses. It is an arguable thesis, however, that such a change might hardly be worth while; that the pappy foods of modern cookery are themselves a part of that form of evolution which we call Western civilisation. Not very good for us perhaps, and bringing with it a train of dental disease and abdominal trouble; yet so intimately bound up with the fabric of our lives that it would not be possible to revolutionise our dietetic environment without also interfering with a great many other things which we regard as essential to our comfort. While over-refined bread is open to criticism we confess that the alternative of raw wheat grains as a way of obtaining starch, which Mr. Starr recommends, leaves us without enthusiasm.

Mr. Starr's premises and conclusions are indeed hazardous speculations. Yet the book is well worth reading. We take evolution so much for granted that it is salutary to have a challenge flung at us which compels us to reconsider the nature of the mechanism by which we suppose that man has evolved from the amœba.

History of Medicine.

Medicine: an Historical Outline. By M. G. Seelig, M.D., Professor of Clinical Surgery in the Washington University School of Medicine. Baltimore: Williams and Wilkins Company; London: Baillière, Tindall and Cox. 1925. Pp. 287. 11*s.* 6*d.*

We are driven to preface our review with a quotation from Macaulay, which, *mutatis mutandis*, describes our frankly unfavourable impression of this book.

> "Nothing in the work has astonished us so much as the ignorance or carelessness of Mr. Croker with respect to facts and dates. . . . The notes absolutely swarm with mis-statements into which the editor never would have fallen if he had taken the slightest pains to investigate the truth of his assertions."

On p. 7 Prof. Seelig says: "In certain primitive races the so-called 'Mica' operation was done, this consisted in making a permanent urethral fistula in those males not considered worthy of propagating the race." The Mica operation has nothing to do with fitness for propagation, for it is performed on every male at the age of puberty and in no way prevents impregnation, as will be seen upon consultation of W. E. Roth's "Ethnological Studies Among the North-West Central Queensland Aborigines," p. 179. On p. 43 we find "The Arab hordes of the South destroyed the Eastern Empire and appropriated its capital, Constantinople, as their own." The destroyers of the Eastern Empire were Turks. On p. 49 we find a statement to the effect that it was Justinian who persecuted the Nestorians, led by the priest Nestorius, and so led to their seeking safety in Syria and Persia. As a matter of fact, it was the Emperor Zeno who was the cause of their flight first to Edessa and later to Persia, and Nestorius was not a priest but a bishop and patriarch of Constantinople. On p. 57 et seq., concerning Salerno, Prof. Seelig says that "it served both as type and a stimulus to the founding of other universities: Bologna in 1110, Oxford and Montpellier in 1180, Paris in 1205." These dates are not accepted, though we allow that to fix accurately a definite date for the foundations is difficult. Bologna, however, held her octocentenary in 1888; the earliest date at which Oxford can be called a university is 1167. There was a school of medicine at Montpellier in 1137, but the earliest allusion to a university is 1220. Paris became a university somewhere between 1150 and 1170, though there had been a school there in earlier days—a migration of alien scholars from which was probably the origin of Oxford. As to Salerno being the type and stimulus of other universities, nothing is more remarkable than the fact that despite the position of the Salerno School of Medicine, the university, so called, for it never was a regular university, had no influence whatever in the development of academic institutions. (Hastings Rashdall, "Universities of Europe in the Middle Ages," Vol. I., p. 82.) On p. 60 we find it stated that the Regimen Sanitatis Salernitanum consisted of "thousands of verses in hexameter." The number of lines in the poem varies in different codices, but the longest is 1239, the shortest is 370, and the mean of five versions is 710. On p. 100 Prof. Seelig says, in talking of the sixteenth century: "The spirit of mediævalism soon debased Plato's creed into what is known as Neoplatonism, a hodge-podge of cabalism, astrology, and alchemy." Can he ever have heard of Plotinus or of Porphyry? On p. 109 Harvey's famous dictum is, with a fine disregard for grammar, quoted as *Omnis vivum ex ovo.* On p. 114 the expression "the cups that cheer but not inebriate" is attributed to Dr. Johnson. On p. 131 James Douglas is described as having discovered "the peritoneal pouch behind the rectum." On p. 160 we find "Of all the pure and naked truths uttered by old Hippocrates, none was purer essence of truth than his famous *Populus vult decipi.*" There may be some statement somewhere in the Hippocratic corpus having the same meaning, but we doubt it, and anyway Hippocrates did not know Latin. The phrase is generally said to have been coined by Cardinal Carafa (d. 1591), who was Papal Legate in France and who used the words in reference to the Parisians. On p. 185 we find the Edinburgh anatomist, Robert Knox, described as John Knox, and the Burke and Hare scandal as an instance of body-snatching, whereas it was murder.

The book is a reprint of eight lectures delivered in the Washington University School of Medicine, with the wish to "make a stimulating appeal to the mind of the student during his plastic medical school period." It is a pity that the work contains so many inaccuracies, for the idea and aim of the lectures are good, and we must give praise to the author for his quotation of Newman's type of a gentleman as given in the Scope and Nature of University Education, as applied to the physician. Dr. Garrison, whose excellent "History of Medicine" is a great contrast to the book now before us, furnishes a somewhat bittersweet foreword to Prof. Seelig's outline.

Pictor's Tract on the Treatment of the Renal Calculus, 1557.

A Facsimile of the Original German Text from a Copy in the Library of Strasbourg University. With an English translation by Charles Greene Cumston, M.D., Lecturer on the History of Medicine and Medical Philosophy in the University of Geneva. London: George Routledge and Sons, Ltd. 1925. Pp. 65. 5*s.*

George Pictor, the author of this little tract, was born at Villigen in the Black Forest in 1500. He was for some time a schoolmaster at Freiburg in Breisgau, but later studied medicine at the university of that city, where he also took his degree. The university offered him a professorial chair, which he refused in order to take the post of stipendiary physician at Einsisheim. He wrote various other medical works, a list of which is given by Dr. Cumston. The book now before us is a popular work, "written for everybody's use." It consists of eight chapters, the third of which tells how to differentiate between renal calculus and the colics. Though a good enough description of renal colic is given, but little help is supplied in differential diagnosis. Other chapters deal with prevention and cure. On the whole the advice is good considering the date of writing. As to prevention, Pictor sums up his advice as follows: "In brief, if stone in the kidney is to be avoided, a regular life must be led." The best part of the book is the dedication to "the Honourable and Learned Gallo Blet . . . my respected Master and Patron," in which Pictor reminds his patron of a reward given to a peasant who had offered him some water, by Artaxerxes. "For this act he honoured this peasant as his friend and even raised him to the rank of a nobleman. Should such a mark of esteem be accorded me, your Excellency would incite me to greater diligence in all circumstances. I would also recommend your Excellency to God and pray that He might accord you happiness and pleasure, and that you might be able to fill your office and govern for a long time to come with God's will and in collaboration with the honourable Dean John Wagnere and others." Surely an appeal to melt the heart of a stone!

Tumours and Cancers.

By Hastings Gilford, F.R.C.S., formerly Hunterian Professor, Royal College of Surgeons of England. London: Selwyn and Blount, Ltd. 1925. Pp. 703. £2 2*s.*

There was a time when no pathologist of distinction could be considered to have placed the coping-stone on his life's work till he had formulated a cancer theory. Nowadays, the actual workers in this field are less prone to indulge in these speculations, and the broader consideration of the subject is more commonly undertaken by the onlookers who, after all, may see most of the game. Fortified in the belief that pedestrianism is not an angelic prerogative, Mr. Hastings Gilford having "flapped his wings, cranked his engines, and wound himself up" (p. 622), has proceeded to attack the cancer problem. He has obviously read widely, the list of authors quoted includes some 1600 names, and thought deeply on the subject, and has arrived at definite conclusions. He believes that the investigation of cancer has hitherto been on far too restricted lines. Needless to say, he has little faith in morbid anatomy and histology which he calls necrology (p. 624), and, admittedly, he is not alone in failing to appreciate that subtle distinction between the killed and the dead cell which is yet sufficiently strong to justify the experimental histologist, to himself at any rate, in his life's work. But experimental cancer research also makes little appeal to him. He says:

> "Engrafted neoplasms of mice are not much better than dolls or idols, as compared with living things and ideals. It is true that these neoplasms are alive, but they are in other respects no more than crude images of that which they are supposed to represent. Even the spontaneous neoplasms of mice, though true biological products, differ as widely from our neoplasms as do mice from men, so that no one would put any reliance upon evidence gathered from their study, unless it tallies with that already gathered from clinical experience and from general observations of the neoplasms of men" (p. 624).

In place of these restricted investigations, Mr. Gilford turns to biology, by which he means any science which has any bearing on the study of life. But inasmuch as he points to syphilis, malaria, enteric fever, and tuberculosis as examples of diseases which defied all efforts to understand them until their secret was revealed by methods of biology, pathologists and bacteriologists may yet take heart, encouraged, indeed, by the knowledge that their culture is deeper and broader than even they themselves supposed. Mr. Gilford sees disease as Nature's punishment—"Cancer is Nature's punishment for heinous biological transgressions. Of this we cannot be rid, until we are led through the paths of knowledge, of realisation of sin and of repentance." Looked at in this light, cancer is malignant but not malicious. Just as the scourge of the itch taught men to wash and, by compelling cleanliness, helped in the destruction of typhus, and enteric fever and cholera compelled us to cease drinking sewage (p. 625), so, Mr. Gilford holds, when its secrets are revealed, will cancer, too, make for our health and happiness. This biological conception of men rising on stepping-stones of their dead microbes to higher things is intriguing, but on this basis one might pause to lament the untimely disappearance of typhus fever, for its lesson might be equally valuable.

Put briefly, Mr. Gilford's doctrine is as follows. Cancer is essentially a disorder of development. The development of some cells may be arrested while that of others may be unduly hurried. In either case the cells are roused into regressive activity by stimuli, when they become cancers—and the stimuli are the evils of civilisation, all the old ones which have already been recognised by other authors, and many new ones including beef-tea, alcohol, and oral sepsis. The arguments on which this thesis is based are voluminous. Some of the author's conceptions are of interest, and some, no doubt, are just, but they are so often supported by simple assertions, by bad reasoning, and by debatable pathology that they fail to carry weight. For example, on p. 404, it is stated that dental sepsis hardly existed a century ago. "To attribute this" (oral sepsis) "to neglect of the tooth-brush is a serious slur on the dental profession, for never before has the tooth-brush been used as it is now, and the dentists of 50 years ago were both scarce and inefficient as compared with the dentists of to-day. Yet caries and oral sepsis, hardly recognised as causes of general disease 50 years ago, are to-day recognised as among the most important of all causes." Surely here the author confuses recognition with existence. On p. 162 we are told that alcohol produces fibrous degeneration of the liver and kidneys by bathing all the cells of the organ with diluted poison. Innumerable examples of this kind could be quoted. While we find that Mr. Gilford's book, founded, as it is, on a large range of reading and practical observation, has an interest for the student of malignant disease, we cannot feel that he has done much more than state in a general way the problem which still remains to be solved.

Manual of Psychiatry.

For the Medical Student and General Practitioner. By Paul E. Bowers, M.S., M.D., Examiner in Lunacy, State of California; Neuropsychiatrist, Los Angeles General Hospital. London and Philadelphia: W. B. Saunders Company, Ltd. 1925. Pp. 365. 18*s*.

Dr. Bowers has produced a book which is compact and comprehensive, and has laid adequate emphasis on the neurological aspect of the subject. The classification adopted is that outlined by the American Psychiatric Association, which appears to be in the nature of a list of mental disorders rather than a schematic arrangement. The book shows evidence of the practical experience of its author; the chapter on Methods of Examination is thorough and that on Treatment is practical. There are a number of tabulated lists—for instance, of the causes of convulsions and of the differential diagnosis of various conditions, which form a useful feature for the revision of knowledge. A long section is devoted to the criminal implications of insanity, each mental disease being discussed in relation to the particular variety of disordered a-social conduct which may arise. The matter in the book is ingeniously arranged and tabulated. The treatment of the subject is rather superficial, but as a handbook for the student the volume is quite adequate.

Landscape Painting.

By Adrian Stokes, R.A. London: Seeley Service and Co. 1925. Pp. 256. 15*s*.

It is probable that this book, which is an addition to the New Art Library, makes a considerable appeal to medical men, as the interest taken by the profession in landscape painting appears to be widespread and spreading. Last year the modest exhibition held at the Royal Society of Medicine produced 60 medical exhibitors without exhausting the number of those who might well have shown their work; and, plastic work apart, of over 200 exhibits all but four or five fell generally under the head of landscapes.

Mr. Stokes's book is an excellent one. The reasoning is clear, the instruction simple and detailed, and the illustrations, where introduced, have a proper bearing on the text. He addresses himself mainly to workers in oil, but tempera work is fully noticed, and the remarks on water-colour painting are useful. The detailed description of the author's work on the beautiful tempera "Autumn in the Mountains," now in the Tate Gallery, is an informing lesson.

With one suggestion of a really practical teacher it is not easy wholly to agree, and we suggest that more than a rudimentary knowledge of perspective will often be found valuable in landscape painting. It is true that the landscape painter need not render angles and vanishing lines on any building that may come into his composition with the accuracy of an architect, but the knowledge of how to do this must surely give him considerable facility in dealing with the surfaces, elevations, and contours of a large landscape. Turner lectured to the Academy on perspective, and though it is recorded that his teaching was unintelligible, he certainly used his intimate knowledge in his own landscapes, while the valuable work on the subject in the New Art Library is written by an accomplished landscape painter.

Mr. Stokes's volume is calculated to induce medical men to develop any taste for painting that they may possess, and to introduce more of our colleagues to a pursuit for which much of their training must have fitted them, and in which they will find a rare source of pleasure.

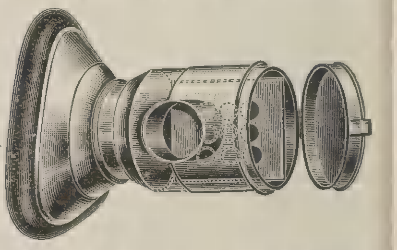
The late Sir James Mackenzie's work on "Angina Pectoris" has been translated into French by Dr. E. Guilleaume, of Spa, and published in Paris by the Librairie Félix Alcan at the price of 25 francs.

Dr. Jamieson B. Hurry's "Vicious Circles in Disease" has been translated into Spanish from the third English edition by Dr. Diego Moxó y Queri, with a preface by Dr. Augusto Pi Suñer. The book is published by the Editorial Médica Mariano Roig, Premiá de Mar, Barcelona, Spain.

New Inventions.

A NEW ANÆSTHETIC INHALER.

I have had constructed to my design an anæsthetic inhaler for which I claim the following advantages. It can be used for nitrous oxide, ethyl chloride, chloroform, C_1E_2 mixture, or ether, open or closed; it is simple in construction and economical in use; anæsthetics can be renewed by opening the lid and dropping them on to the pad without removing the inhaler from the patient's face; and when used for closed anæsthesia very little vapour escapes into the atmosphere. In operations requiring a lateral position of the head, one is able to keep well away from the field of operation, and the work of the surgeon is interfered with much less than when using an ordinary mask. The inhaler consists of a metal face-piece, shown in the illustration, with sorbo-rubber face-cushion, between which and a rubber bag of 1½ gallons capacity is a metal cylinder divided into two compartments, one of which is filled with a pad of absorbent material to take the anæsthetic. A sump catches any excess of anæsthetic. At the distal end of the rubber bag is a tap to which an oxygen tube can be attached. By removing the bag the inhaler can be used for open anæsthesia, and by adjusting it, for closed anæsthesia.



The inhaler is made for me by Messrs. Philip Harris and Co., Ltd., Edmund-street, Birmingham.

THE LANCET.

LONDON: SATURDAY, MAY 23, 1925.

OPHTHALMIC BENEFIT UNDER THE INSURANCE ACT.

It is said that the number of medical practitioners trained in ophthalmic work is at present insufficient to undertake the treatment of the large numbers of insured patients who are likely to take advantage of the suggested ophthalmic benefit under the Insurance Acts. It is on this ground largely that opticians who already supply glasses in connexion with the so-called "optical benefit" provided by some of the larger approved societies are being proposed to carry on this work. In connexion with this subject, let us in the first place consider the relations of the public services to ophthalmology in the immediate past and at the present time.

1. *Education.*—The school system has been the pioneer agency in this respect and the establishment of school clinics all over the country in the hands of medical practitioners trained in ophthalmic work provides the nucleus of the required service.

2. *The Army.*—One of the most significant features of the medical services during the war was the organisation of an ophthalmic medical service. That it was possible to do this while continuing to provide for the needs of civilians at home is a fact that should be noted. The efficient coöperation of the optician was, of course, essential and will be freely acknowledged.

3. *Pensions Service.*—Following the war came the work of the Ministry of Pensions, and in this the same specialists who served the nation in the army have carried on their work until the main problems have been settled and little remains to be done in the ophthalmic branch of the Pensions Department.

4. *Insurance Service.*—Only a very few of the approved societies have made arrangements by which their members may obtain the advice of ophthalmic surgeons under the Insurance Acts. The term "optical benefit," in insurance regulations, refers to a special benefit which has been established by some of the larger societies by means of which patients who think they need spectacles are helped to obtain the services, not of an ophthalmic surgeon, but of a sight-testing optician. The opticians are moving to get this system extended and perpetuated. On the other hand, we have reason to believe that the Ministry of Health are finding a better way.

We do not deny that, although there are many so-called sight-testing opticians who are not competent to correct any but the simplest cases of refraction, there are others more competent. It is the declared object of their leaders, as expressed week by week in their journal, the *Optician*, to enforce a high standard of competence in this respect and to obtain for those opticians so qualified the hall-mark of State recognition, so that the anticipated general extension of the so-called optical benefit under the Insurance Acts may fall to their lot to administer. Does it not stand to reason that these sight-testing opticians, if they succeed, will establish themselves as a privileged body of practitioners without medical qualification but with the kudos of State recognition, who will tend more and more to monopolise the treatment of diseases of the eye? Such an ambition may be repudiated in the published writings of the opticians concerned, but actions speak louder than words. They have already established a "Refraction Hospital" in London where the use of the ophthalmoscope is taught, and they are taking steps to do the same in other cities. It may be said why, if they make themselves competent to deal with cases where nothing but an error of refraction is concerned without any involvement of the general health, should they not be recognised as such? The answer is twofold. In the first place, we may remark that medical benefit is granted for health insurance and should not be granted for objects in which the health of the insured individual cannot be considered involved. In the second place, defects in the ocular refraction *are* frequently closely connected with the individual's health; we may instance the connexion between astigmatism and headaches in young adults, and the occurrence of premature presbyopia as an early symptom of glaucoma. How often it happens that ocular symptoms afford a clue to local or general disease is made very clear on a perusal of Mr. Percy Flemming's address in our present issue. But already there are signs that the ambition of the sight-testing optician is to become an ophthalmic consultant. "A fair proportion of sight-testing opticians," says a writer in the *Optician*, "are more skilled in the detection of ocular diseases than the majority of medical practitioners."[1] The argument is, of course, that the optician who discovers a disease with which he knows he is incompetent to deal will refer his patient for more highly skilled advice, but the gap between diagnosis and treatment is, after all, not so great in many cases as between ignorance and diagnosis. It would seem that if the opticians get their way they will in time become a body of privileged non-medical practitioners who will acquire vested interests in the treatment of insured patients. Is this to the public good?

And what is the alternative? It is said that the average general practitioner is not sufficiently often competent to deal with cases of refraction and that the number of competent ophthalmic specialists is so small that it would be impossible for them to deal with all the insured population. With the former statement we may to some extent agree, with the latter we do not. The appointment at many of the greater hospitals of special refraction assistants in addition to the clinical assistants who in the past dealt with a large part of this work; the continually growing number of education authorities who provide for refraction work (in 1920 the number was 280); the growth of ophthalmic private practice in the country—many specialists have consulting-rooms in several centres, so that it is probably true to say that there is no section of the country where a patient would sacrifice more than half-a-day's work in order to have his refraction tested and eyes examined by an ophthalmic surgeon; the number of those who have already answered the appeal recently issued by the British Medical Association and Ophthalmic Benefit Committee,[2] and have professed themselves willing and able to deal with these cases: all these circumstances combine to show that the problem which it is said cannot be solved except by calling in the aid of unqualified practitioners is not insoluble. The question has been raised, however, Are these considerable numbers of ophthalmic surgeons who are volunteering to do the required work at a fee of one guinea for each completed case of refraction competent to do the work? Dr. FREELAND FERGUS, of Glasgow, whose paper on Miners' Nystagmus is given on another page, has lately published a brochure entitled "What is an Eye Specialist?" which is gleefully quoted in the pages of the *Optician*, for Dr. FERGUS throws doubt on the competence of many of those practitioners who claim to be ophthalmic specialists, chiefly on the ground that they have an insufficient knowledge of physical and physiological optics. With much of what he says we are in sympathy. Undoubtedly most qualified men and women need a course of at least two years' post-graduate intensive study before they can acquire the necessary familiarity with the problems with which they will be faced as ophthalmic specialists. At the same time we do not agree that the facility in the employment of mathematical formulæ which is called for in dealing with the more difficult problems of theoretical optics is an essential requirement. The important point is that some means must be found whereby the special competence of the men and women who may volunteer to do this work may be ensured. The idea that anyone possessing a medical qualification should start to learn his ophthalmic work by getting experience at the expense of insured patients is wholly indefensible. He must have had actual practice in hospitals of ophthalmic work and he must be prepared to afford evidence that he has already acquired the requisite skill in this branch of practice before he can be recognised by the State as competent for this special purpose. The proposals of the joint committee already published to ensure this object are a good beginning, and we understand that further machinery is being elaborated by means of which their intentions may be carried out. On the success with which this is done much may depend.

---

HOMES OF RECOVERY.

THE modern hospital with its special departments, its operating theatres and laboratories, is increasingly expensive to build and to maintain, and, as our diagnostic technique grows, the expense is likely rather to increase than diminish. It is therefore becoming the practice to maintain in the country or by the sea homes of recovery to which patients can be sent when it is no longer necessary for them to continue under treatment in the parent hospital, while they are not yet fit to be sent either to a convalescent home or to their own homes. During the last three or four years the financial position of voluntary hospitals has so greatly improved, their annual receipts and expenses have so nearly balanced, that the question of extension is again becoming practical. Nearly every voluntary hospital committee in the country has reported the need for more accommodation, and in the aggregate some thousands of additional hospital beds are said to be required in England and Wales. That being the case, the right use of the auxiliary hospital becomes a pressing issue. Of the value to parent hospitals of homes of recovery, auxiliary hospitals, country annexes, or whatever we may choose to call them, there has never been any reasonable doubt. What is good for the hospital should be good for the patient, but there is some difference of opinion as to the precise character of the advantage enjoyed by the hospital. At last week's conference of the Incorporated Association of Hospital Officers, reported on another page, there was an interesting discussion on the subject provoked by the paper read by Dr. F. N. KAY MENZIES on the financial aspect of the auxiliary hospital. He was concerned to inquire into the extent to which the auxiliary can relieve the pressure upon the beds and consequently upon the finance of the parent institution; the facts and experiences which he marshalled had forced upon him the conclusions that when a patient has reached a certain stage of recovery his retention in the town hospital is uneconomic, and that substantial savings can be made by drafting him to a recovery branch. Some of Dr. MENZIES's critics, and those not the least authoritative, were inclined, for technical reasons, to be doubtful about the pecuniary savings—they were uneasily conscious of a flaw in his argument, but did not find it easy to put their finger upon it. Evidence was, however, not lacking that substantial economies can be, and are being, made by the extended use of homes of recovery.

It is obvious that strict finance is not the only side of the question. The object of a hospital is to cure its patients as surely and as quickly as possible, both for its own sake and for theirs, and that cure is more rapid in the cleaner air and more reposeful surroundings of the country is the merest truism. If, therefore, an auxiliary hospital failed to make any savings for the parent house, it would still abundantly justify its existence. When, however, it not only sends the patient back into the world some days earlier than would be possible if he remained in the town hospital, but saves sums of money which, in the aggregate, are imposing, there is little room left for argument. It is not every great hospital that can be moved from its central position—the Middlesex Hospital is an apposite case in point—but there is abundant need for more auxiliary hospitals.

What effect the more economic use of parent hospital beds will have on the staff remains a matter for consideration. It is stated by those who know that the medical and nursing staffs of London hospitals are already working nearly up to the breaking-point, and, if the stream of patients is to be more rapid, it will be necessary at all events to augment the staff of nurses. It will not be practicable to employ probationary nurses at an auxiliary hospital unless there is a resident medical officer, for the General Nursing Council would not recognise such employment in the prescribed training. This difficulty might be met by linking the nursing staff of the auxiliary with the parent hospital, probationers passing from one to the other, and, if necessary, by combining the annexes of various hospitals in order to have an auxiliary hospital large enough to require a resident medical officer. These are some of the questions on which more information is needed, but they do not invalidate the argument for providing more auxiliary hospitals. Economy and psychology both point to the importance of multiplying them.

SAFEGUARDING MEDICAL PRACTICE.

DURING the past year the risks to which doctors may be exposed in the work of their calling have been brought prominently before the medical profession through two cases which aroused a great deal of public interest, the Harnett case and the Bateman case, and it is to be hoped that the lesson contained in these two unfortunate occurrences will impress upon a still greater number of medical men the necessity for securing adequate protection for themselves through membership of one or other of the great medical defence societies.

The London and Counties Medical Protection Society held their annual meeting on May 20th at Victory House, Leicester-square, London, when an interesting and instructive report of the Society's work in 1924 was submitted by the council. The solicitors, Messrs. Le Brasseur and Oakley, stated that 1924 might be regarded as one of the heaviest litigious years in the annals of the Society, but of the eight cases which went for trial, excluding smaller county court cases, one cause only was lost. In the case of Harnett *v.* Bond and Adam, involving principles of vital importance to the medical profession generally, the whole of the expenses incurred by Dr. Adam, who was a member of the Society, were borne throughout by the Society. The outcome of this case decided the council to make provision by insurance for an unlimited amount so that a member could be completely indemnified under all circumstances, the limit of indemnity for defraying damages incurred by a member having previously been limited to £3000. (A similar step was also taken by the Medical Defence Union.) Apart from litigation, over 409 cases were dealt with by the Society's solicitors, who point out again how important it is that a member should not, through fear of delay, act on his or her own initiative, but should place the case from the first in the hands of the Society. The report, as usual, records a number of most interesting and instructive illustrations of difficulties encountered and overcome with the help of the Society, and covering all branches of medical life. Space alone prevents us publishing in these columns a larger selection than the following :—

A member had a claim made against him by the father of a child whose ear it was alleged had been damaged by the doctor's violence in quieting the child's struggles during the administration of an anæsthetic. Considerable difference of opinion arose amongst the experts consulted. Negotiations were commenced with a view to a settlement by way of a solatium and this was satisfactorily arranged, all charges against the member being unreservedly withdrawn.

A member without any request from him had had left at his house various articles connected with his dental profession. Demands for return of the goods or for payment were ignored by him, and as a result county court proceedings were commenced against him. The Society considered that this was a case which should be defended on behalf of the member in the interests of the profession in general, and, on the plaintiff's solicitors being written to informing them of the intention to defend, the proceedings were immediately abandoned.

A Scottish member of the Society was dismissed by his parish council from the appointment of parish medical officer, but the consent of the Scottish Board of Health had not been obtained. The case was fully considered and was reported to the Scottish Board of Health and an inquiry requested. Through the Society's Scottish agents the case was very fully investigated, a large number of witnesses were obtained on the member's behalf, and a full inquiry was held by the Scottish Board in a remote Scottish island, with a result that the member's dismissal was quashed and his reputation entirely upheld.

A member received a solicitor's letter accusing him of having disfigured a patient's face by negligent use of X rays for the removal of superfluous hair. After inquiry it was found that the disfigurement had been caused by various quack remedies which the patient had used and not by the X rays. The findings were sent to the patient's solicitors and no further communications were received.

A member received a letter from a solicitor demanding an apology and compensation for making "malicious and slanderous statements" about his client in the presence of a number of students. Inquiry showed that the patient had been seen by the member's deputy at a hospital out-patients' department, where the cause of the patient's disease was discussed and blood was taken for the Wassermann test. The solicitor was told that it was absurd to suggest that a doctor was actuated by malice because he took steps to exclude the possibility of the patient's illness being due to a serious constitutional disease. No further action was taken.

With regard to medical secrecy, the council considers that it is the duty of a medical man *not* to disclose the nature or circumstances of the disease or illness from which his patient is suffering unless he is satisfied that the inquiry is made by a near relative who has a bona-fide obligation to maintain the patient or to assist in securing the comfort or the recovery of the patient. Such disclosure is not to be made in any case where the patient is able to consent and has not actually consented. This rule does not apply when there is a statutory obligation to disclose (this includes insanity and notifiable diseases), or where the disclosure is ordered by a competent court of law.

A member was called to a woman suffering from an obscure abdominal condition. The patient's husband, in the patient's presence, told the doctor that he (the husband) had gonorrhœa and had infected his wife. Some time later the doctor was asked by a solicitor to give evidence on behalf of the wife in divorce proceedings. Our member asked whether he ought to give evidence in the case. He was advised that, as the husband did not give the information about himself as a patient, and as his patient (the wife) wanted him to give evidence, he might properly do so.

In the present unsatisfactory state of the law, the Society is unable to do as much as could be wished in the way of suppressing unqualified practice. Where, however, the law provides a trustworthy remedy against unqualified practice, the Society is always ready—on the request of a member, backed by sufficient evidence—to put the law in motion.

A member asked whether he might properly send patients for treatment to a radiologist who did not possess a medical qualification. He stated that the radiologist was experienced and did work for a hospital. He was told that he could not be held legally liable for negligence in having suggested to his patient that he should go to the radiologist, because he had good reason to think the radiologist was entirely competent. He was, however, further advised that the General Medical Council would hold that a practitioner must either retain or denounce responsibility for the treatment of his patient. If he retains it he must supervise the treatment given on his direction by an unqualified person ; if he definitely renounces it, the patient on his own responsibility may seek treatment where he will.

The Society issues a warning against laxity in granting medical certificates under the National Health Insurance Act, which is very seriously regarded by the General Medical Council and by the Ministry of Health. "In our experience," the solicitors state, "members, on the grounds of humanity and with a view to alleviating the lot of their poorer patients, are tempted to stretch a point in the patients' favour, and they should be warned against so doing as they are taking a risk which may seriously affect the whole of their professional career."

ROYAL COMMISSION ON NATIONAL HEALTH INSURANCE.—The twenty-eighth meeting of this Commission was held at the Home Office, Whitehall, on May 14th, Lord Lawrence of Kingsgate in the chair. Evidence was given on behalf of the National Medical Union by Dr. Vivian Greenyer, chairman of the Council of the Union, and Dr. Charles Thornton Comber, member of the Council ; and on behalf of the Scottish Medical Guild by Prof. William Russell, President of the Guild, and Dr. Frederick Porter, secretary. These witnesses submitted various criticisms of the health insurance scheme on its medical side, and urged a reversion to private arrangements, except for necessitous persons for whom a State medical service should be provided. Thereafter Dr. Harry Roberts gave evidence as to the working of the Act in a large panel practice in Stepney, and Lieut.-Colonel Bickerton-Edwards submitted a number of suggestions for organising medical treatment and improving the conditions of the insurance practitioner. Proof copies of the oral evidence and the relative statement submitted at the meeting of April 30th are on sale at H.M. Stationery Office (3*s.*).

Annotations.

"Ne quid nimis."

POPULATION.

THE population of England about A.D. 1000 was something like 1½ millions; it slowly grew to nearly 9 millions in 1801, and then jumped up till it reached 38 millions in 1921. A hundred years ago Great Britain had twice the population of Ireland; now it has ten times as many people. Which, Mr. A. M. Carr-Saunders says in a recently published volume,[1] is a thing the like of which has, as far as is known, never happened before and will, as far as may be guessed, never happen again. The theoretically possible multiplication of mankind is infinitely great compared with the available area of land and its utmost imaginable fertility. Birth restriction, Mr. Carr-Saunders holds, is a necessity, and the customs of primitive peoples show that it has always been practised; the modern mind differs from the ancient only in asking for reasons instead of being content with religious or customary sanctions. The author is a classical Malthusian, and his argument centres round the proposition that the best number of people is that which gets the largest return out of collective human work and so achieves the highest general standard of material and spiritual life. Nomadic life fills the world with *n* persons per square mile, agriculture with 2 *n* or 10 *n*, according to its development, industrial concentration with 100 *n* or 1000 *n*. Whether any part of the world is over-populated or not depends therefore on the control which man can exert over his environment. That this will increase may be presumed; it appears likely that the population of this country is reaching, or has already reached, a stable condition; there is no need for alarm, but a great necessity that the situation should be studied and understood. Such is, briefly, the main thesis of a most excellent little book. The author states the questions and argues them very clearly and gives us one of the best half-crown's worth we have ever seen. Population, birth control, urbanisation are matters in which a great variety of people take, and ought to take, an interest; they are of national and international significance, and if such a book as this were widely read we should do away with some of the nonsense that is talked and printed about them. The book is short and in places necessarily dogmatic; it gives, however, an admirable survey which will incite the reader to go further and study some of the works given in the bibliography at the end, in which, curiously enough, there is no mention of the author's larger book "The Population Problem," published by the Clarendon Press in 1922. On one point only would we offer a suggestion. Mr. Carr-Saunders points out that nations desire to be big because they so add to their prestige, because they like as many people as possible to be of the same ideals and prejudices as themselves, and because they can more easily wave the big stick. He entirely omits the point which appeals strongly to the biologist, and especially the biometrician—that large populations are more likely than small ones to contain those exceptional variants on whom the progress and guidance of the world so much depend.

SIGNIFICANCE OF MANY TUBERCLE BACILLI IN THE SPUTUM.

IT is generally assumed that the number of tubercle bacilli in the sputum is directly proportional to the severity of the disease. Another common belief is that the appearance of these bacilli varies with the severity of the disease, short and homogeneous bacilli being supposed to be indicative of severe disease, whereas granular and moniliform bacilli are supposed to be coughed up by patients whose disease is comparatively slight. To provide a statistical verification of these views, Dr. T. Stefani and Dr. J. Stefani,[1] of Montana, have compared the clinical with the bacteriological findings at their sanatorium in the period 1898–1923. Of the 1430 patients treated, only 781, or 55 per cent., were sputum-positive. There were 303 patients in whose sputum tubercle bacilli could not be found, and 346 who did not provide sputum for examination. In 70 per cent. of the 781 sputum-positive cases, the views referred to in the opening sentences of this annotation were confirmed. Cases in which the disease was slight were marked by a paucity of tubercle bacilli in the sputum, cases in which the disease was severe were marked by the great number of bacilli, and according as the patients became better or worse, the number of the bacilli in the sputum became less or greater. In 8 per cent. these correlations were reversed, and in the remaining 22 per cent. the dwindling or augmentation of the numbers of bacilli in the sputum bore no uniform relationship to the clinical course of the case. A comparison of the appearance of the bacilli with the course of the disease showed that in 60 per cent. of all the sputum-positive cases the orthodox teaching held good. When the disease was slight, most of the bacilli were granular, when it was severe, they were short and homogeneous, when the patient was getting better, granular bacilli replaced the homogeneous bacilli, and when the patient became worse homogeneous bacilli again appeared. In 18 per cent. these correlations were reversed, and in the remaining 22 per cent. no uniform parallel could be drawn. By combining the two factors—both the number and the appearance of the bacilli in the sputum—the authors of this interesting paper show that in as great a proportion as 80 per cent. a clue is given by the microscopic examination to the prognosis. Their painstaking research is confirmatory of views held for a long time. It is so much less exciting to confirm than to subvert old teachings that the authors are to be congratulated on having conducted investigations without that incentive to work which some of us find in the prospect of proving another in the wrong.

INSULIN AND INFECTION.

THE article in our present issue by Dr. R. Carrasco-Formiguera, of Barcelona, on the amount of insulin required in the treatment of the surgical complications of diabetes and Dr. G. Graham's article on the relation of infection to diabetic coma in the current number of the *Quarterly Journal of Medicine*, both draw attention to the relation of sepsis to diabetes and of the necessity of giving an adequate amount of insulin. Dr. Carrasco-Formiguera points out that there is an impression abroad, for which he regards Dr. E. P. Joslin of Boston as partly responsible, that insulin is of little value in the presence of sepsis. He thinks that this is solely due to the use of an insufficient amount of insulin, although the dose given by Dr. Joslin—namely, 80 units in the day—would be considered a large dose under ordinary conditions. The amounts which Dr. Carrasco-Formiguera has used have been very large. Thus in one case in which a carbuncle was present on the neck, no less than 240 units were given on the first day although no food was taken. During the next week 200 units were given each day together with increasing amounts of food. Although the patient recovered in this case, it does not follow that a diabetic patient will always recover from another disease, however well the diabetic condition is handled with insulin. When such large doses of insulin are being given it is advisable to have estimations of the blood-sugar made at least once a day if possible and to test the urine for sugar every two or three hours. In an emergency it is safe to give large doses of insulin provided that the urine is tested in this way and that insulin is not given when the urine contains no sugar, provided always that the symptoms and signs of insulin hypoglycæmia are clearly recognised and its treatment remembered. Dr. Graham also found it necessary to give large doses of insulin, although his maximum dose was only 160 units in the day. The point which he has made is the relation of an acute infection to the onset of diabetic coma. In seven out of nine cases of coma an acute infection was present, but was only obvious in two cases on admission to hospital. In two cases a definite pathological lesion would have been discovered at an autopsy if the patient had died in coma, while in three cases it is probable that no lesion would have been discovered, since the signs of an otitis media in one case and of an abscess in the antrum of Highmore in another did not appear until some days after the patients had recovered consciousness. These observations show the importance of searching for an acute infection whenever the patient shows diminished sugar tolerance or becomes comatose. Dr. Carrasco-Formiguera describes the beneficial effects which took place in the healing of a large wound following small doses of insulin, although the diabetic condition was obviously of the mildest. This is a point which needs further investigation, since insulin may prove to be of definite assistance to the surgeon in the treatment of chronic wounds.

THE TREATMENT OF CHRONIC DRUNKARDS.

THE treatment of the chronic drunkard is always a difficult problem and on the whole the solution in this country along the lines laid down by the Inebriates Acts of 1879–99 seems to be fairly satisfactory, particularly when compared with the state of affairs in France, for example. In that country the number of chronic drunkards is increasing very rapidly, and Prof. Maurice Letulle last year made a striking appeal for the provision of "drinkers' asylums,"[1] where these unfortunate creatures may be kept under restraint and suitably treated, for at present, unless the drunkard is definitely insane or unless he commits some criminal offence under the influence of drink, he is given no chance of placing himself under any restraining régime. In England there is likewise no system of compulsory restraint for the non-criminal drunkard, but there exist certain homes for inebriates where private patients are received as well as those who apply for admission under the Inebriates Act, and the forty-first annual report of Dalrymple House, Rickmansworth, which we have just received, illustrates effectively the beneficial results of restraint on these cases of alcoholic addiction. During the last year 59 patients were admitted to this home, 51 as private patients and eight under the Act. All were cases of alcoholic excess, and the absence of drug case admissions is attributed by the medical superintendent, Dr. F. S. D. Hogg, to the carrying out of the Dangerous Drug Act regulations, which he considers have so reduced the incidence of cases of habit-forming that further amendments to that Act are unnecessary. We referred in commenting on last year's report to the fact that the after-history of 1645 cases showed that 40 per cent. were doing well, and inquiries with regard to the results of treatment amongst those who have been discharged during the last few years show that 56 per cent. were definitely doing well, excluding those cases about which no information could be obtained. Dr. Hogg remarks upon the alteration in the symptoms of excessive alcoholism which has taken place within recent years, particularly in cases of even moderate spirit-drinking. Toxic symptoms, such as partial blindness, loss of memory, delusional states associated with early excitement and slow recovery, are more frequent than hitherto, and it is suggested that this is due to the adulteration of whisky with cheap deleterious alcohols by certain dealers being now a more frequent practice than before the war. It has, however, recently been pointed out[2] by Dr. R. Hunt, of the Harvard Medical School, that the toxicity of "boot-leg" liquors submitted for analysis was sufficiently accounted for by their content of ethyl alcohol. The beautiful situation of Dalrymple House, as shown by illustrations to this report, the indications that the social side receives careful attention, the provision of a workshop, &c., all emphasise that one of the important factors in the treatment of chronic alcoholism is environment. The other important factor, that of régime, doubtless receives due attention at the hands of those who have made a long study of this disorder, but it would be interesting to know if the hours of meals, for example, as set out in this report, are rigidly adhered to, for the 14 hours which appear to elapse between dinner and breakfast must feel long to those with a morbid craving.

THE FOOD VALUE OF CEREAL FOODS.

IT has long been known that rickets tends to develop most readily in children fed on diets which contain much carbohydrate, especially when the content of protein is also low. Feeding with condensed milk has been supposed to be particularly liable to lead to the development of rickets, and the main lines of treatment now recognised are to increase the amount of anti-rachitic vitamins, to give plenty of sunlight, and to bring about a proper balance between the protein and carbohydrate of the food. Investigations by Prof. E. Mellanby have shown that puppies develop rickets most readily when large amounts of bread are eaten, and subsequent experiments showed that the calcification of bone depends on the operation of several factors. These factors have been recently discussed by him in a Green book (No. 93 of the Medical Research Council Special Report Series), which was summarised in THE LANCET of April 11th, p. 789. In an investigation on the comparative influence of different cereals on the development of rickets, he has produced what appears to be incontrovertible evidence that the carbohydrate content of the diet is by no means the only factor concerned. First there is the confirmation of the view that when the anti-rachitic vitamin is deficient, increasing the cereal content of the diet leads to the production of far worse rickets. Next it is shown that the different cereals show great individual differences in their rickets-producing effects under such conditions, the least detrimental being wheat, the worst by far being oatmeal—a statement which, as our Scottish correspondent pointed out not long ago, has raised a storm in the porridge-bowl. Prof. Mellanby's experiments seem to show that these cereals exert a definite pro-rachitic influence on bone development, which influence can be wholly or in part antagonised by the anti-rachitic effect of vitamin A or sunlight. The anti-rachitic effect of cod-liver oil is far greater than that of other sources of vitamin A, though egg yolk and milk are also potent. So also are various calcium salts, especially the carbonate and phosphate, when taken with butter. It is claimed that the pro-rachitic effect of oatmeal, which is exhibited in spite of the fact that it contains much more calcium and phosphate than wheat, is due to the fact that it contains a substance, or on digestion yields a substance, which exerts a definite inhibitory effect on bone formation. The calcium content of the diet, provided there be enough calcium for bone formation, appears to be of secondary importance. The essential fact is that, in order to avoid rickets, the diet must show proper balance, there must be enough calcium and phosphorus, anti-rachitic vitamins must be present, and there must not be an excess of the cereal component of the diet, which would, by supplying a pro-rachitic factor, oppose the normal growth and formation of bone.

---

[1] Le Progrès Civique, July 12th, 1924, p. 984.

[2] Jour. A.M.A., April 18th, 1925.

As Prof. Mellanby says, "there is a constant battle going on among dietetic elements as regards the calcification of bone, some substances stimulating and others preventing the process, and the ultimate structure of the bone is the outcome of the conflict."

The final word on this matter may not be said for a long time to come. Prof. Mellanby has performed a great amount of careful experimental work, which is worthy of serious consideration, and has raised issues of which we had not previously thought. But, on the other hand, it is certain that his results should be applied with caution to problems of human dietaries. The great amount of prominence which has been given to work on the vitamins, and to allied questions in the science of nutrition, largely on account of the conditions of restriction of choice which were imposed on us by the war, is in danger of leading to an exaggeration of their importance. Everyone who has worked on nutrition will admit that in a properly chosen diet the vitamins will look after themselves, and it is only under special circumstances that it becomes necessary to take special vitamin-containing foods. Without question the same applies to the regulation of diet in connexion with the prevention of rickets. While Prof. Mellanby's results have undoubtedly great scientific value, they are in danger of being misunderstood by lay people, many of whom take a great interest in diet. It must not be forgotten that the diets given to the puppies under experimental conditions are highly abnormal diets for such animals, and would not be chosen voluntarily by them. It might be suggested, for instance, that a diet of meat would probably lead to definite disturbances in the economy of a growing human infant, but it would be foolish to argue from such an experiment that meat is an unsuitable article of diet for puppies. Conclusions from these valuable and suggestive experiments should not, then, be pushed too far, and it must not be forgotten that Prof. Mellanby would certainly be the last to apply them unreservedly to human nutritional problems. The matter must be subjected to further careful investigation before we can say how far they can be applied.

THE ADMINISTRATION OF PURE OXYGEN.

IT is not often that pure oxygen is administered to patients, but when such administration is required it has long been the custom to use the ordinary apparatus for nitrous oxide anæsthesia, substituting a cylinder of oxygen for one of gas. This method was used by Beddard and Pembrey [1] in their early work on the effect of oxygen. Its practical disadvantage as a routine method in the wards is that it requires the constant supervision of a nurse to regulate the flow of oxygen to keep the bag filled. The advantage of Haldane's apparatus, which came into use at the end of the war, was that the expiratory valve on the mask also acted as an air inspiratory valve, as required, so that if the supply of oxygen suddenly ran short the patient would breathe atmospheric air, and constant supervision to prevent suffocation was not necessary. Some oxygen is, of course, lost by this method. Dr. H. W. Davies and Dr. A. R. Gilchrist have recently in THE LANCET [2] elaborated the older method by adding a flow metre to measure the oxygen, a reducing valve on the cylinder to steady the flow, and an adjustable opening to the mask, so that the concentration of oxygen in the air breathed can be varied. Such alterations, though presenting obvious advantages, may still lead to certain practical difficulties, and it would be interesting to know if they have been met. Is constant supervision of the apparatus still necessary? Reducing valves are very apt to leak, since the junction between valve and cylinder head has to stand the total internal pressure of the cylinder. Again, the Haldane reducing valve offers so much resistance that the last part of the oxygen of the cylinder often fails to escape. Have these facts been taken into account? While everyone who has studied the subject would agree with the authors that the method of giving oxygen by a funnel is useless, it does not necessarily follow that the extremely simple method of giving oxygen through a nasal catheter or a tube passed into the mouth should be condemned. No reducing valve is required, and the rate of flow can be gauged by the rate at which the oxygen bubbles through water in a bottle, though a flow meter is preferable. Such a method will not give pure oxygen and there will be some waste, but the inspired air will be considerably enriched and the patients benefited. When *pure* oxygen is required, the method of gas-bag with mask and valves in some form or other is essential. Perhaps the chief indication for pure oxygen is coal-gas poisoning, since the higher the concentration of oxygen the more readily will the CO be excreted from the body and the patient recover. Dr. Leonard Hill and Dr. Argyll Campbell, in their paper in the same issue of THE LANCET, mention Dr. Haldane's observation that a mouse poisoned with CO can be kept alive in pure oxygen under two atmospheres of pressure. The technical difficulty of administering oxygen under pressure to patients is considerable, and fortunately in coal-gas poisoning pure oxygen under atmospheric pressure is good enough. However, the use of oxygen under increased pressure may be of advantage, since it has been pointed out that a perfect gas and oxygen anæsthesia with no cyanosis can only be obtained by such means. The reason is that such a high concentration of nitrous oxide is necessary for the anæsthesia, that the oxygen must be deficient if the ordinary atmospheric pressure is used, and visions have been conjured up of surgical operations being carried out in a steel chamber. An alternative method is to choose a gas with greater anæsthetic power, such as ethylene, so that perfect anæsthesia by means of ethylene and oxygen without oxygen-want may be obtained. Unfortunately, ethylene is highly inflammable, though there is every prospect that with proper precautions it may come into regular use for special cases.

CRIPPLING DUE TO FRACTURES: THE REMEDY.

THE Lady Jones Memorial Lecture in Orthopædics in the University of Liverpool was delivered this year by Sir Robert Jones on May 12th before a large and representative audience of the medical profession. The lecturer chose as his subject Crippling Due to Fractures, its Prevention and the Remedy. After some preliminary remarks designed to emphasise the great frequency of preventable deformities after fractures, he dealt with the different types of disablement that might be present and the simple way in which most of them could be obviated. He instanced more particularly the serious results following badly treated fractures of the neck of the femur, the supracondylar region of the humerus, and the lower end of the fibula. He pointed out plainly that students were not adequately trained in the treatment of fractures and that this was often because the general surgeon had not the interest in nor the up-to-date knowledge of the treatment of fractures necessary if the subject was to find the place in his teaching which its importance to the man in practice demanded. To some extent this was inevitable, as the field of general surgery was now too large to be profitably traversed by any one man. The lecturer then entered a plea for a better thought-out and more efficient scheme for the education of the student. Every teaching hospital, he said, should have its special fracture department—usually, no doubt, in association with an existing orthopædic department. It should be under the charge of a man of consultant rank or if shared between several, an assistant of high standing should be appointed, whose specific duties should be the supervision of the department under his various chiefs. The department should include ward accommodation and out-patient rooms in close contact with the X ray and physiotherapy departments. A house surgeon and a permanent specially trained sister were, of course, essential. The lecturer held that attendance of senior students on at least a dozen demonstrations and classes for practical instruction should be compulsory. It was estimated that in a general hospital 10 per cent. of the beds should be set aside for the treatment of fractures. Should this be found impossible it was far better that hospital authorities should frankly disclaim responsibility. Wards could then be secured in Poor-law hospitals, and properly staffed and equipped these could be brought into vital connexion with the teaching schools.

THE LEICESTER PRIVATE HOSPITAL.

ON May 20th a private hospital was opened in the Regent-road, Leicester, following a largely attended reception, arranged by the Leicester Medical Society. The hospital is the gift of Mr. T. Fielding Johnson, formerly chairman of the Leicester Royal Infirmary. The object of the donor has been to make available for the use of private patients the advantages of a modern hospital, and the medical profession know well how exactly such institutions meet the present-day needs. The position of those who require hospital treatment, while they definitely cannot expect that their needs should be met by a charitable institution, though domestic circumstances preclude treatment at home, has hardly received the public attention that it deserves. At the relief of this position Mr. Johnson's generosity is directed, and he is to be much congratulated upon its sensible nature. The new institution has been built and equipped as far as possible with the facilities and conveniences of a voluntary hospital, and, the capital outlay having been found, it is intended to be managed on a self-supporting basis in regard to future maintenance and upkeep, there being accommodation for 50 patients, mostly in single rooms. All medical practitioners can recommend their patients, for whom there will be no restriction in the choice of doctor, and provision has been made for the reception of maternity cases as well as medical and surgical patients. We look forward to receiving an early report upon the working of this institution, for its success may prove a stimulus to communities as well as individual donors.

AN UNSUSPECTED EFFECT OF AIR POLLUTION.

IT is now well known that a large proportion of the water supplied by the Metropolitan Water Board is treated with a minute quantity of chlorine in order to facilitate bacterial purification, and the same method has been adopted by a considerable number of water authorities. The only objection to the process is that even when the chlorine is added in the proper proportion the water on occasion acquires an iodoform flavour and sometimes a distinct odour of this compound. The cause has been an entire mystery until an acute observer, Mr. B. A. Adams, F.C.S.,[1] noted that the odour and taste only occurred under certain meteorological conditions, and that rain-water collected under these conditions when chlorinated acquired the same characteristic odour and taste. His further researches revealed the fact that the taste and odour were due to a trace of phenol or an allied body, doubtlessly taken up from the smoke-contaminated atmosphere. With pure phenol he found that when added to a pure water in the proportion of one part to 1000 millions of the water, the taste was marked directly after adding the chlorine, but that a lady could detect 1 part in 2000 millions. These remarkable results have been more than confirmed. Experimenting with waters of different types it was found that practically every person could detect an iodoform odour when the phenol was 1 in 1000 millions of certain waters and some could detect a taste when the proportion was 1 in 5000 millions. The latter proportion represents 14 grs. of phenol in 1 million gallons of water, and it seems quite possible that water exposed to air in an open reservoir could take up this quantity from the atmosphere under certain conditions such as Mr. Adams found were necessary to cause the water to give the iodoform flavour when chlorinated. The nature of the body found capable of giving this flavour is uncertain, but its intensity is obvious when it is found by calculation that one five-millionth of a milligramme is capable of being detected by the taste. It is obvious that such tastes could be prevented in two ways, either by excluding the water from contact with air or by preventing atmospheric pollution from smoke. The one is in most cases possible, the other at the present practically impossible, but the fact above recorded may be of interest to the Meteorological Office Advisory Committee on Atmospheric Pollution. Smoke-contaminated air when bubbled through pure water causes it to give the iodoform reaction with chlorine, and this may suggest another method of determining the extent of the pollution of air by smoke.

BROADCASTING HEART SOUNDS.

UNDER the supervision of Dr. R. Lutembacher, who is well known in Paris as a heart specialist, the beats of one healthy and six diseased hearts were recently broadcasted from the Eiffel Tower station. Dr. Lutembacher has hopes that in the future by this means a doctor may be enabled to follow the progress of a patient, though he does not suggest that a complete diagnosis of a case previously unseen would be possible. He declares that by the aid of an amplifier a patient's heart beats are clearly audible over an ordinary telephone. A further valuable feature of such experiments is that they may bring the country doctor and the hospital specialist into closer touch. This experiment is said to be the first of a series. We recorded attempts on similar lines at Bristol and in Charlottenburg last year (THE LANCET, 1924, i., 861). Radio transmissions have since been carried out on several occasions by the Welsh National School of Medicine from the British Broadcasting Company's station in Cardiff. On one occasion two cases with well-marked cardiac bruits were correctly diagnosed by a medical man in Somerset. However, the aim of these transmissions was not so much to test the value of broadcasting heart sounds for the purpose of diagnosis of progress as to obtain information with regard to their magnification many hundreds of times by means of thermionic tubes. If a high degree of amplification without distortion is possible, then we have a new line of approach for investigating the nature of these sounds. It is possible that further light may be thrown upon the mechanism of their production or that vibrations hitherto undetected may be revealed. In exceptional circumstances the broadcasting of a patient's heart sounds might be of benefit, in that expert opinion not available at the bedside might be obtained from a distance. But it is probable that a short account of the patient's condition and symptoms would be more likely to bring help than the transmission of his heart sounds through the ether.

THE next session of the General Medical Council will commence at 2 P.M. on Tuesday, May 26th, when Sir Donald MacAlister, the President, will take the chair and give an address.

THE house and library of the Royal Society of Medicine will be closed on Whit-Monday, June 1st.

GRESHAM LECTURES.—A series of four lectures on the History of Medicine from the Earliest Times to the Mediæval Period, about A.D. 1400, will be delivered by Sir Robert Armstrong-Jones at Gresham College, Basinghall-street, London, E.C., on Tuesday, May 26th, Wednesday, May 27th, Thursday, May 28th, and Friday, May 29th (with lantern slides on this day), at 6 P.M.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CXXIII.—TREATMENT OF DEFORMITIES DUE TO INFANTILE RICKETS.

THE deformities due to infantile rickets commonly met with in practice and requiring treatment are the early stages of spinal curvature, genu valgum and varum, tibial curves, flat-foot, and, rarely, curvature of the bones of the upper extremity. Thoracic deformities require no treatment, and true rickety coxa vara is rare, though the possibility of the occurrence of this and of pelvic deformity is an additional reason for a period of recumbency during the treatment of the active disease.

General Treatment.

During the active period, whether deformity is present or not, the general scheme of treatment is relief from weight-bearing, without curtailment of muscular action, open air and sunlight, corrected diet, and cod-liver oil. This combination is best obtained in one of the many excellent country hospital homes or children's orthopædic hospitals now available.

The above indications can be met, under institutional conditions, by fastening the infant on his back to the cot with a light shoulder harness, which prevents him sitting up or rolling over, but leaves his limbs completely free. He lives in the open air wards with the lightest possible coverings consistent with adequate warmth in winter and at nights—completely in the open, with no coverings, in the day in summer. Helio-therapy is given to those who pigment well. The diet is fat-containing, modified according to age, and generally supplemented by cod-liver oil. The limbs are massaged, and deformities, if present, moulded, but not splinted. It is not advisable to divide or fracture bones during active rickets. Signs of active disease disappear, usually, in three months. The best working test of this is the return of the X ray appearances of the lower radial epiphyses to normal. The child is then allowed to sit and stand, and later, deformities, if persisting, are dealt with by one of the methods given below. Treatment on these lines prevents the formation of deformities and often results in spontaneous disappearance of those already present. When the child has to be treated at home a similar régime should be attempted. Artificial may be substituted for real sunlight. The mother is instructed to keep the child off his feet at least part of the day, the diet is corrected and supplemented, and cod-liver oil given. I am not in favour of splinting the legs to prevent walking, as this limits the valuable effect on metabolism of muscular contraction, and the possible prevention of some increase in deformity is not, in my opinion, sufficient compensation.

The treatment of the common deformities which have persisted in spite of, or arisen for lack of, treatment on general lines must now be considered.

Spinal Curvature.

This is usually (1) a kyphosis in the lower dorsal region, or (2) lateral curvature in the upper dorsal region and at the dorsi-lumbar junction. These are postural deformities, the latter caused by habitually carrying the child on the same arm—the former by sitting.

In kyphosis, immobilisation on the back, as described during the active stage, is sufficient to prevent further deformity. Later, and in the case of older children untreated in the early stages, a course of Swedish remedial exercises is given, and a light Jones brace may sometimes be beneficial till muscular control is improved. Kyphotic children should have school desks at which they can sit upright, and errors of refraction, especially myopia, should be corrected.

Lateral curvature is treated in the early active stages on a plaster bed holding the spine straight or slightly curved in the opposite direction. Subsequently, Swedish remedial exercises are given by a trained masseuse, and, if there is any tendency to relapse, a moulded leather jacket should be worn, made from a cast of the body in suspension, with the spine held curved in the opposite direction to the deformity. This is put on lying down in the morning and only removed for exercises and at night. In more severe cases of scoliosis, with fixed structural deformity, institutional treatment is indicated for a series of plaster jackets to obtain the best correction possible, followed by Swedish remedial exercises and wearing of a moulded leather support to prevent relapse.

Genu Valgum and Flat-Foot.

I mention these together as they are often associated and the early treatment of each is similar. Genu valgum is a deformity produced and increased in the rickety child by standing. Flat-foot is caused by failure of the flabby musculature of rickets to develop the arch of the foot: a process which occurs in the normal child on beginning to stand and walk. The former deformity tends always to produce or increase the latter by faulty weight transmission. A slight degree of genu valgum is common, especially in girls, and, if not associated with flat-foot or an in-toeing gait, requires no treatment. An in-toeing gait is caused by the patient's efforts to support his weakening arches with his invertor muscles by inverting his feet as he walks, and is often a sign of early genu valgum. If these symptoms are present, or the genu valgum more marked, the boots should be raised ¼ in. or ⅓ in. on the inner side of the sole and heel by thickening the leather or adding wedges. The heel counter should be very accurately fitted, and, in some cases, the inner side of the upper may be specially stiffened to prevent treading over. The mother is told *never* to allow the child to stand without the altered boots on. If this is necessary for a few minutes in bathroom or bedroom, the child should learn (as children do easily) to stand and walk on the outer sides of his feet. Simple exercises should be taught to children over 3. The best for flat-foot are (1) with toes pointing inwards, rising on tiptoe and coming down on outer sides of feet, (2) walking on outer sides of feet, (3) (seated) raising and bringing together the forepart of the feet till the big toes touch, keeping heels on the ground, and a few inches apart. For genu valgum—double knee-bending and stretching with the feet separated. Young children with genu valgum should lie down for two hours or so in the day, with a small firm cushion placed between the knees, and ankles and knees tied together with slings or large handkerchiefs. If these measures fail, or if the genu valgum is more advanced, with a separation of say 3 in. and over between the internal malleoli, when the knees are extended and the femoral condyles touching, the alternatives are (1) instrumentation, (2) osteotomy of the femur. Thomas's knock-knee iron is the best instrument. In applying it, the knee, in extension (but not hyper-extension), must be first bandaged to the posterior bar and then pulled over to the lateral bar (which should be set out a little) by means of a webbing strap and pad of felt over the internal condyle as far as the patient will tolerate. The correction is increased as tolerance is established. The instrument corrects efficiently in a year or two if well supervised, but causes much lateral mobility of the knee and muscular wasting if worn night and day. This may lead to relapse unless careful observation, altered boots, and exercises are continued for a lengthy period. I now prefer osteotomy. This should not be done under 4 years of age. The femur is divided with an osteotome for three-quarters of its thickness and the remainder fractured. It is done from the outer or inner side, just above the condyles, with the knee flexed and a firm sandbag behind it. The limb is fixed at once in plaster in slight varum, with hip and ankle included. The plaster may be removed in eight weeks, and weight-bearing, modified by crutches or sticks for the first week, allowed.

Flat-feet in older children, which are painful, or in which the arch cannot be restored by muscular effort, should be put in plaster in full inversion and dorsiflexion for a month and then treated by altered boots and exercises. If the flat-foot is rigid and the arch cannot be restored by manipulation, a preliminary wrenching under anæsthesia must be done until the foot is fully mobile and the arch can be restored. It is then put in plaster as above.

Genu Varum.

This is an outward bowing of the femoral and tibial shafts, causing wide separation of the extended knees when the feet are in apposition. It is not generally associated with flat-foot and tends to decrease with growth, so that treatment is not a matter of urgency. Should it persist after the age of 6, correction, if desired on cosmetic grounds, is obtained by osteotomies of the tibiæ first, followed by division of the femora later, if necessary.

Tibial Curvatures.

The commonest tibial curve (and the most characteristic deformity of rickets) is an antero-external bowing of the lower half or third of the shaft. This is a sitting deformity produced by the child squatting with legs crossed under the thighs. Less commonly the curve is anterior in the lower half, or, rarely, involving the whole shaft like congenital syphilis. Occasionally a tibial curve exactly compensates genu valgum and, functionally, these cases do not require correction. Straightening of the tibiæ for cosmetic reasons will have to be followed by correction of the unmasked genu valgum. Tibial curvature is an unsightly deformity and, if persistent after the age of 3 or 4, should be corrected.

The method of choice is *osteoclasis*. This is a simple procedure. Both tibiæ may be done at a sitting as shock is not great. Under full anæsthesia the point of maximum curvature of the tibia is applied to the narrow edge of a wooden wedge covered with a layer of wool. The weight of the body is suddenly thrown on to the hands, grasping the shaft of the tibia above and below the deformity, and the bone fractures with a crunching sound. A greenstick fracture is usually produced with bending or sometimes fracture of the fibula. Care must be taken in a low osteoclasis not to displace the lower tibial epiphysis by pressing on the foot. Occasionally the bone cannot be fractured by hand, in which case an osteoclast may be used, if available. Osteotomy should not be done immediately if manual osteoclasis fails, as the wound is liable to become infected owing to the preceding damage to the tissues. A firm bandage over wool should be applied and osteotomy deferred a week or so. After fracture the curve is corrected by moulding, but the line of the tibia should not be made too straight. There is normally a slight inward curve of the shaft. The leg is put in plaster immediately. This includes the knee, and the upper portion down to the fracture is allowed to harden slightly before the remainder, including the foot, is rapidly completed. This allows the final correction to be obtained by moulding before the lower portion sets. Any inward rotation of the lower fragment must be corrected at this point. The foot should not be dorsiflexed too much or an angulation of the fracture may be caused.

In older children, or when manual osteoclasis fails, the deformity is corrected by osteotomy. The leg is placed on a firm sandbag and the tibia partially divided with an osteotome subperiosteally, through a very small incision at the site of the deformity. Sometimes, especially in anterior curves, a wedge must be removed. The remaining bone is fractured, the small wound sutured, and the deformity corrected and put up in plaster as described.

Upper Extremity.

Deformities are rare but occur occasionally in the crawling stage of infancy. They are simple bends of the humerus or radius and ulna, and, if persistent after treatment in the active stage, can be corrected by osteoclasis and plaster fixation.

W. B. FOLEY, F.R.C.S. Eng.,
Assistant Surgeon, East London Hospital
for Children, Shadwell.

Special Articles.

THE MILK-SUPPLY AND ITS IMPROVEMENT.

BY WILLIAM G. SAVAGE, B.SC., M.D. LOND.,
COUNTY MEDICAL OFFICER OF HEALTH, SOMERSET.

I.—ESSENTIALS OF THE PRESENT POSITION.

THE present position can be summarised as follows :

1. The recent investigations on dietary essentials have increased the emphasis to be placed upon the value of milk as an article of food.

2. The consumption of milk per head of population in this country is very low. It is rather under one-third of a pint per head as compared with one pint in U.S.A.

3. The milk industry is capable of material increase and could be profitably expanded, with great advantage to the agricultural community, to meet the needs of an increased consumption.

4. While the medical profession as a whole is in favour of an increased consumption of fresh milk in the interests of the nutritional efficiency of the nation, its support cannot be given to an active campaign with this object because of its knowledge of the unsatisfactory quality of the present milk-supply.

5. The present milk-supply is unsatisfactory because, as regards the general supply : (*a*) No effective steps are taken to prevent human tuberculosis being acquired from milk derived from infected cows. (*b*) The conditions under which milk is produced fall a long way below what modern hygiene demands as necessary, and there is no effective control over the conditions of production. In consequence, ordinary market milk is heavily contaminated with bacteria, some of which are harmful and all undesirable. (*c*) The supervision of milk subsequent to production is inadequate, and many undesirable conditions exist.

6. While the distributory milk-trade is anxious to supply a better article it is unwilling, or unable, to control the quality of the milk which is supplied to it. In general it has improved its own methods, but these, in the main, consist in preserving an initially heavily bacterially contaminated article by artificial means, pasteurisation being largely employed.

7. Control over pasteurisation methods employed to preserve the saleability of contaminated milk is non-existent. Pasteurisation may effect its immediate object of prolonging the " life " of the milk without destroying pathogenic organisms.

8. There is no inducement to the individual milk producer to supply a better quality milk unless he has a local market and can earn a reputation for the quality of his milk. The great bulk of the milk produced receives the same price, clean or dirty.

9. The present conditions of milk production and distribution entail unnecessary losses upon the milk-trade, which in the aggregate are very considerable. If these could be measured a clean pure milk would probably be found to be advisable as a business proposition, apart from any health factors.

10. The existing legal powers to control and ensure a pure milk-supply are extremely unsatisfactory and wholly inadequate.

11. There is insufficient care of milk in the homes of the consumers.

12. The scheme of graded milks established under the Milk and Dairies (Amendment) Act, 1922, while of considerable educative influence, touches but the fringe of the problem and cannot be regarded as satisfying the needs of a pure milk-supply.

Most of these postulates are so well recognised that detailed consideration is unnecessary ; others will require discussion to secure their acceptance.

Importance of Milk as a Food.

It is unnecessary to discuss the dietetic value of milk or the importance of its vitamins. In connexion with vitamins in milk, recent investigations have shown that the vitamin content of milk is materially influenced by the food given to and the fresh-air conditions of the cows. A good milk requires, as one of its essentials, production under conditions which do not impair the vitamin content.

Consumption of Milk.

Between 1871 and 1914[1] the population of Great Britain increased by 60 per cent., but the number of cows and heifers by only 40 per cent. The total weight of dairy produce imported during this period increased from 2·5 cwt. to 8·5 cwt., an increase of 235 per cent. The same report gives the average daily consumption of milk per head for Great Britain as 0·25 pint liquid milk. This varied from 0·1 pint in Inverness to 0·31 pint for London.

In a coal-mining district (Rhondda U.D.) Dr. J. D. Jenkins[2] (the M.O.H.) gives the figures of milk consumption per head per day from 1915 to 1923 as 0·15 (1915), 0·14, 0·15, 0·105, 0·167, 0·167, 0·152, 0·165, 0·175 (1923). These figures show a progressive increase, but it is slight. Even the highest figure is less than one-fifth of a pint per head per day, and in nine years the increase is only one-fortieth of a pint per head.

There are no statistics that I am aware of dealing with the actual consumption in individual families, particularly in rural areas. In view of the importance of milk as a food I have instituted some inquiries in different villages in Somerset (a milk-producing county), limiting the investigations to families which comprise children at public elementary schools. The results are summarised in Table I.

TABLE I.—*Milk Consumption.*

Parish.	No. of families investigated.	No. of inmates.		Total weekly consump. in pts.	Average consump. per head in pints.		No. of families, with consumption :		Highest and lowest consump. per head per week.
		14 and under.	All.		Per week.	Per day.	Above the mean.	Below the mean.	
A	30	95	173	378	2·18	0·31	16	14	4·7—0·8
B	30	102	169	435	2·59	0·37	17	13	7·0—0·87
C	10	21	49	163	3·32	0·47	6	4	5·6—1·1
D*	47	92	221	674	3·05	0·44	24	23	7·0—1·0
E	29	72	166	416	2·50	0·36	16	13	5·25—0·9
F	14	50	82	228	2·78	0·40	6	8	7·0—1·4
G	10	32	57	124	2·17	0·31	4	6	3·5—0·9
T'tal	170	464	917	2418	2·64	0·38	—	—	— —

* D is a quite small town mainly occupied with gloving (population about 1000), the others are rural villages.

All the inquiries were made in January, 1925. The average consumption per head per day was 0·38 pint or practically one-third of a pint per person. This is above the calculated average for England generally, but these families all include children. Practically no condensed or dried milks were being used, so no allowance is necessary for this. Unfortunately, also, it was frequently the families with the most children who obtained the least milk. Table II. gives particulars of the number of children in the families consuming one-third or less than one-third of a pint per head per day.

Table II. shows that 42·4 per cent. of the families consumed one-third or less milk per head per day. The group of 170 families investigated included 45 with four or more children, and in 32 of these, or 71·7 per cent., the available milk per head per day was one-third or less pints. The larger the number of children and the greater the need of milk the less they received. The low average consumption in village A was connected with the fact that 11 of the 30 families contained four or more children, and in ten of these the milk consumption was less than one-third of a pint per head per day. Inquiries showed that there was no difficulty in obtaining milk, although a few of the children objected to drink it.

TABLE II.

Parish.	Number of children 14 and under in family.					All.	Per cent. of families investigated.

The two essential causes of the low consumption are a failure to appreciate the importance of milk as a food and the cost, many mothers stating they were unable to afford more. The price paid was 2½*d.* to 3*d.* a pint in winter.

Increase in Milk Production in this Country.

Another Government report[3] states that in 1922 the total production of milk in Great Britain was estimated to be 1320 million gallons and the consumption of liquid milk at 650 to 700 million gallons, while the quantity of milk imported as represented by milk products is estimated at 1570 million gallons. In 1922 the estimated total consumption of milk and milk products was computed at 2890 million gallons, of which home production furnished 1320 million gallons, or approximately only 46 per cent. of the whole. There is a need for an increased production of milk to meet an increased use of milk which should be stimulated and to produce in this country what is imported from abroad. Agricultural authorities are of opinion that a very great increase of milk production is practicable.

The Dilemma of the Medical Profession.

If the consumption of milk is to be increased the support of the medical profession must be enlisted. At present the individual practitioner is in a dilemma. On the one hand, he knows the importance of milk as a food, particularly for children and for the sick under his care, and he favours a general increase in its consumption. On the other hand, he is well aware that most of it is produced under grossly insanitary conditions yielding a milk laden with living bacteria, some of which are definitely pathogenic. How can he recommend such a fluid in its raw condition? Again, he knows that boiled and heated milk is not the equal of raw pure milk. He is driven to accept the lesser evil and advocate milk only when boiled or efficiently pasteurised, but it is difficult and nearly impossible to secure his active coöperation as an apostle for its widespread consumption while conditions remain as at present. Graded milks form such an inconsiderable quantity of the total supply that he is not helped much thereby. I have felt the dilemma in lecturing upon milk, in connexion with health weeks, &c., having to devote the first part of my lecture to an exposition of the advantages of milk as a food and the latter half to an explanation of the necessity for a pure supply and the dangers of ordinary milk.

Tuberculosis from Milk.

It will be unnecessary, in view of the extensive literature on the subject, to do more than try and assess the extent of tuberculosis in man of bovine origin. The subject is discussed in detail by Cobbett,[4] while a very valuable paper by Stanley Griffith[5] gives a clear statement of the present-day position. Tables III. and IV., summarised by Gauvain from Griffith's paper, are of great interest.

It is possible from these figures to arrive at an estimate of the number of deaths due to bovine tuberculosis. Cobbett has made the calculation, and concludes that at least 6 per cent. of tuberculosis deaths are of bovine origin, or rather over 3000 deaths a year. As Sir Henry Gauvain points out, this is probably an under-estimate and will be found to be higher when larger numbers of cases of abdominal and generalised tuberculosis are classified according to the type of bacillus. In addition to the cases, which end in death, there is the immense number of cases with less fatal lesions, many of which are severely affected for years, while a good many die from other diseases. At least 50 per cent. of the gland tuberculosis cases are of bovine origin, cases which are not fatal as such.

Nearly all these bovine cases are of milk origin and we must agree with Gauvain: "There can be no question that bovine tuberculosis is a very fruitful source of disease in this country. No form of food-supply is the direct or indirect cause of more deaths, and for no food product is so little done to prevent infection as in the milk-supply of this country."

It is difficult to arrive at comprehensive facts as to the extent of tuberculosis amongst milk cows and the degree to which milking herds contain animals shedding tubercle bacilli into the milk-supply. Local reports as to the presence of tubercle bacilli in milk do not supply much grounds for believing that there is any material reduction, although facts suggest that in some areas there is a diminution. Probably there is about 1 per cent. of milking cows with tuberculous udders, and about 12–15 per cent. of mixed milk samples show living tubercle bacilli.

Considerable campaigns are now being launched and a great deal of money is, and will be, expended on dealing with cripples and other children suffering from tuberculosis. It may be philanthropy, but do not let us call it business or preventive medicine, to allow unchecked the manufacture of large numbers of cases of tuberculosis of bovine origin and then spend huge sums to try and restore these unhappy victims to a condition of health of which they should never have been deprived. To give but one example. In Shropshire their orthopædic work is a model to other counties, and during 1923 the sum of £4434 was paid by the county council for the treatment of surgical cases of tuberculosis. It we take the above figures for bone and joint tuberculosis as 20 per cent. bovine and apply this to the whole, £887 was spent on the treatment of a few of the cases of bovine tuberculosis, an expenditure which could be more advantageously employed in eradicating the sources of infection.

(To be continued.)

PROCEEDINGS OF THE ROYAL COMMISSION ON NATIONAL HEALTH INSURANCE.[*]

(Continued from p. 1046.)

EVIDENCE OF THE INSURANCE COMMITTEES.

EVIDENCE was given on behalf of the Federation Committee of the English, Scottish, and Welsh Associations of Insurance Committees by the Rev. W. D. Yoward, Mr. Edwin Potts, Mr. W. N. Marshall, and Mr. F. Llewellyn Jones (App. XXXVI. and Q. 12696–13142). Separate statements were put in by the two last named on behalf of the Scottish Association (App. XXXVII. and Q. 13143–13208), and on behalf of the Welsh Association (App. XXXVIII. and Q. 13209–13270).

This evidence is largely devoted to an account of the way in which medical benefit is administered by the insurance committees and contains many of the provisions of the acts and regulations which need not be reproduced here. It is stated that insurance committees have taken a very deep interest in their work and have displayed an active interest in all matters pertaining to national health, including a large share in health propaganda.

The staffs of committees were, at the outset, largely recruited from the offices of local authorities, and their earlier experience has proved most useful. The Associations claim that they should be directly represented on behalf of insurance committees on any body or conference negotiating the terms of service with the doctors. They consider that they should be brought into consultation from the commencement. The right of any medical practitioner to inclusion on the panel list should, they suggest, be restricted and an inquiry made before admission to the service where the insurance committee make representations to that effect. The doctors' representatives themselves would, it is said, welcome this as tending to improve the service. Amongst other things which would be the subject of inquiry would be the adequacy of the surgery and waiting-room accommodation.

---

[*] In previous articles the proceedings of the Commission were reported under the following headings: Introductory Note; The Scope of the Insurance Scheme (see THE LANCET, Jan. 31st, pp. 247–8); The Provision of Medical Benefit (Feb. 7th, pp. 301–3; Feb. 14th, pp. 355-6; Feb. 21st, pp. 403–5); Financial Provisions of the Act (Feb. 28th, pp. 454–7); Medical Certification and the Regional Medical Staff (March 7th, pp. 508–9); The Approved Societies and the Money Benefits (March 14th, pp. 564–5; March 21st, pp. 623–4); Evidence of the Hearts of Oak Society (March 28th, pp. 677–9); Evidence of the National Conference of Industrial Assurance Approved Societies and of the Manchester Unity Approved Society (April 4th, pp. 731–3); Evidence of Independent Order of Rechabites, of Rational Association Friendly Society, and of Miners' Societies (April 11th, pp. 784–6; April 18th, p. 839); Evidence of Mr. Alban Gordon (April 18th, pp. 839–40); Evidence of Joint Committee of Approved Societies, of Stock Exchange and Lloyds' Health Insurance Societies, and of Group of Catholic Approved Societies (April 25th, pp. 889–91); Evidence of the National Insurance Beneficent Society (May 2nd, pp. 943–4); Evidence of the British Medical Association (May 9th, pp. 993–5); Evidence of the British Dental Association and other Dental Organisations (May 16th, pp. 1044–6).

References to the paragraphs in the printed statements issued as appendices to the reports of the oral evidence are given thus; "App. X. 69," and references to the oral evidence thus—Q. 1369.

In regard to medical certification, it was suggested that the issue of recommendations for treatment benefit—e.g., dental treatment—should no longer be restricted to occasions on which a certificate of incapacity for work is given. Penalties recommended by the insurance committees should not be varied by the Ministry without the insurance committees being afforded an opportunity of stating their views. Other alterations of machinery proposed included a simplification of the arrangements in connexion with the transfer of practices and an extension of the duties of regional medical officers in consultation in the earlier stages of illness.

With regard to administration, the Federation saw no necessity for the insurance medical service being placed in the hands of an authority which provides no part of the cost. An extension of the service to the dependants of insured persons would not, in itself, strengthen the argument for unification with the local authority services.

> (Q. 13041.) Effective coördination and unity may be secured by coöperation between these bodies, strengthened by interlocking or reciprocal representation and by joint sub-committees, including arrangements for joint action by officers of these bodies.

Extensions of the Medical Service.

Insurance committees are of the opinion that the various treatment benefits should become primary benefits and be administered by the insurance committees. There should be a complete domiciliary service developed in the following order of priority: (*a*) Consultants and specialists; (*b*) diagnostic and treatment facilities (laboratories and clinics, &c.); (*c*) nursing; (*d*) dental treatment; (*e*) ophthalmic treatment; (*f*) additional appliances; (*g*) maternity services; (*h*) massage. Beyond these there should be provided hospital and convalescent home treatment, medical services for aged persons, and an extension to the dependants of insured persons.

The Federation were not prepared to give any estimate as to the cost of these proposals. They felt that there was money available in the scheme for some, at least, of these services. As regards an increased contribution to cover any part of the services, the witnesses said (Q. 13053): "We have not anything definite to put forward on that." Mr. Marshall added that in Scotland they were definitely against any increase in the contribution at the present time.

The separate Scottish evidence included the statement (Q. 13219) that if the health functions of insurance committees were transferred to County Councils, those bodies would not be able to cope with the work, as they are already overburdened. In regard to the present insurance medical service, it is stated (App. XXXVII., 26) that the local medical committees take a broad and, indeed, a generous view of the duties of the doctor to his patient.

Other statements of interest are as follows: (46) The Association is not satisfied that the mileage grant for Scotland is sufficient. (60) The Association believes that without in any way impairing efficiency, considerable economies in the supply of drugs to insured persons might be effected.

The Welsh evidence contains the suggestion that the Commission should be invited to consider the advisability or otherwise of the approval of new institutions for administering medical benefit. Evidence definitely recommending this course was put forward by the Glamorgan Insurance Committee in Appendix XXXIX.

Separate evidence was laid before the Commission by the Coventry Insurance Committee (App. XXXIII. and Q. 12237–12451), which included the suggestion that, with a more fully developed medical service, insurance committees might become related to the local authority more or less on the lines of the Education Committee.

The Cheshire Insurance Committee gave evidence (App. XXXIV. and Q. 12452–12659) on the detailed administrative work of a county insurance committee, the way in which the service might be extended, and the application to a county area of an attendance system of remunerating insurance practitioners.

The Leicestershire Insurance Committee (App. XXXV. and Q. 12660–12695) gave evidence especially on the extent to which the Insurance Committee had conducted health propaganda by means of posters, articles in the local press, appeals to the clergy and Sunday schools to coöperate during Health Week, and illustrated health lectures to school-children. They suggested that insurance committees could be especially useful in this direction, as they are directly concerned in the provision of medical treatment of the industrial population.

HOSPITAL OFFICERS' ASSOCIATION.

ANNUAL CONGRESS.

THE second annual Congress of the Incorporated Association of Hospital Officers was held on Friday last at St. Thomas's Hospital. After a brief address of welcome by the Hon. Sir Arthur Stanley, the congress was opened with equally commendable brevity by the President of the Association, Mr. W. H. Harper, house governor and secretary of the Wolverhampton and Staffordshire General Hospital.

The Rôle of the Auxiliary Hospital.

Viscount Hambleden then took the chair for the morning session, and Dr. F. N. Kay Menzies, Director-General of Hospital and Medical Services for the Joint Council of the Order of St. John of Jerusalem and the British Red Cross Society, read a paper on The Auxiliary Hospital: its Financial Aspect and the Extent to which it can Relieve Pressure upon Parent Hospital Beds, by himself and Mr. R. H. P. Orde. Their paper appears at substantial length on p. 1115 of this issue.

The discussion was opened by Mr. E. W. Morris, house governor of the London Hospital. While agreeing with the need for country annexes, he thought that insufficient attention had been given to matters other than financial which give them their value. Patients did much better in the country, but they always stayed much longer there than in the parent hospital. The weekly cost of a country bed was probably less than half the town cost, and there was the collateral advantage that pupil probationers could be taken in a women's annexe at the age of 19 and afterwards drafted for training into the parent hospital. On the other hand, a probationer who has entered at 21 and is being trained in the town cannot be sent to the annexe because all annexes have not a resident medical officer, and unless they have the General Nursing Council will not recognise them as training schools for nurses. Some of the town hospitals might combine to have an annexe large enough for a resident medical officer; otherwise the annexe must be run entirely by fully-trained nurses, which would be expensive. At the same time he felt that from the financial point of view there was a flaw in Dr. Menzies' calculations, though he could not put his finger on it.

Dr. H. L. Eason, superintendent of Guy's Hospital, agreed that every hospital ought to have many more auxiliary homes, but made the point that, even with a high daily average of unoccupied beds, the medical staffs of the London hospitals were very near the breaking point, and that if patients were got through the hospitals more rapidly that strain would be increased and it would be necessary to augment the nursing staffs. Whatever the other advantages of country annexes the idea that they would save money was illusory. To this opinion Mr. A. G. E. Sanctuary, administrator of the Radcliffe Infirmary at Oxford, opposed the fact that about £1 per week per patient was saved to that institution by sending patients to its home of recovery. He suggested that the cottage hospitals might be used as annexes. Mr. Frank G. Hazell, secretary of Manchester Royal Infirmary, and Mr. G. G. Panter, secretary of the Royal Northern Hospital, bore witness to similar experience. Mr. Arthur Griffiths, secretary of the East Suffolk Hospital, Ipswich, said that it had been found at that institution that although the recovery hospital did not reduce costs, it expedited the complete recovery of the patient. The President declared that his auxiliary hospital not only reduced costs but enabled patients to return home three or four days earlier. Lady Wilberforce, hon. secretary of Marlow Cottage Hospital, thought that the auxiliaries should help in the training of probationers at an earlier age. Mr. Orde, co-author of the paper, having claimed that the financial advantages of auxiliary hospitals were admitted by the most practical economists, Lord Hambleden drew attention to a nursing difficulty. A large proportion of the cases sent to auxiliary hospitals are surgical, and it is not easy to find medical cases in sufficient number for the training of probationers to the satisfaction of the General Nursing Council. In his reply on the discussion, Dr. Eason thought that this difficulty might be removed by linking the nursing staff of the auxiliary with the parent hospital, probationers passing from the one to the other.

Contributory Schemes.

At the afternoon session, at which Dr. Eason presided, Mr. A. G. E. Sanctuary read a paper on the Effect of Hospital Savings and Contributory Schemes on Voluntary Contributions. Contributory schemes meant financial stability and consequent efficiency, and he argued that the intelligent philanthropist will more readily support an efficient institution which is holding its own financially than one which is struggling along on the verge of bankruptcy, and that consequently contributory schemes were likely to increase rather than diminish help from subscribers. He believed, indeed, that contributory schemes had saved the voluntary system from extinction; there were many hospitals that would have failed but for the establishment of these schemes.

Mr. F. B. Elliot, general secretary of the Hospital Saving Association, considered that Mr. Sanctuary had completely proved his case. The problem was peculiarly difficult in London owing to the multiplicity of hospitals and to their never having made it their business to work together. Mr. Elliot gave some significant figures of the progress of the Hospital Saving Association during the two years of its existence. In its second six months its workmen contributors expanded from 33,000 to 62,000; in March last they numbered 135,000, and were now close upon 150,000. In the first six months to January, 1924, the income was at the rate of £16,000 a year; in the first three months of 1925 it was at the rate of £76,000, and in April of £87,000. In reply to questions, Mr. Elliot stated that the working expenses amounted to rather more than 10 per cent., paid out of a guarantee fund. In the course of a useful discussion the question was raised whether hospitals benefiting by contributory schemes entered into a contract of service with the contributors, and Dr. Eason replied that there was no such contract either implied or in fact, and there was no certainty of admission. Patients presenting vouchers from the Hospital Saving Association were, however, exempt from all almoner's inquiries and made no payment to the hospital. The system had not, as some people had feared, flooded the out-patients' departments.

Mr. Harper reminded the conference that the Wolverhampton contributory scheme had been in existence for nearly half a century, and said that in the last ten years the amount raised by it had enormously increased. He had no belief in joint hospitals' councils and was strongly of opinion that contributory schemes ought to be worked from inside each hospital.

At the close of the congress the members were the guests at tea on the terrace of the House of Commons of Mr. George Harney, M.P., and Captain Styles, M.P., and in the evening they dined together at the Holborn Restaurant.

ROYAL SOCIETY CONVERSAZIONE.

SCIENTIFIC EXHIBITS.

A CONVERSAZIONE was held at the Royal Society on the evening of May 13th. A number of demonstrations was given and many exhibits of great interest and instruction were shown.

The exhibit of pure fused quartz ware by the Thermal Syndicate, Ltd., included the atmospheric type of mercury-vapour lamp for medical and research work, hypodermic syringes for flame sterilisation, and some optical quality fused quartz lenses.

The Cambridge Instrument Co., Ltd., showed some typical applications of the thermal conductivity method of gas analysis. The method depends essentially on the varying heat conductivity of different gases, this change being registered as a change in the rate of heat loss from a platinum spiral electrically heated and placed in the gas to be examined. Any alteration in the composition of the gas mixture, for example, oxygen and carbon dioxide, is reflected as a change of resistance of the wire provided that there is an appreciable difference in the thermal conductivities of the two gases, and this is the case with the two gases mentioned. The change in resistance may be conveniently recorded by means of a sensitive galvanometer. The principle was used originally in the Shakespear katharometer for the analysis of flue gases, and has recently been applied to biological work. For example, Prof. A. V. Hill has made use of this method for determining the percentage of CO_2 in the alveolar air. The measurement of the CO_2 production of a single fly was demonstrated on this occasion by the Cambridge Instrument Co. The percentage of CO_2 rose fairly rapidly to a value of about 11 per cent., thereafter remaining constant at that figure for a comparatively long interval. Unfortunately, the thermal conductivities of oxygen and nitrogen are so nearly identical that so far it has not been found possible to apply the method to the measurement of oxygen consumption.

Some early wireless apparatus was shown by the Science Museum. The exhibit included instruments used by Sir Oliver Lodge at a lecture to the Royal Institution in June, 1894, in experiments with Hertzian waves, on which occasion wireless signals were transmitted through walls a distance of some 20 yards; also part of the first tuned coupled circuit apparatus of Senatore Marconi.

The Director, Rothamsted Experimental Station, demonstrated two lines of research in connexion with *Bacillus radicicola*, the nodule organism infecting leguminous plants. The organism passes in the soil at certain periods into an active flagellated stage, and it was found that the appearance of this stage could be promoted by inoculating the soil with the organisms suspended in milk and that this effect was increased by the addition of phosphate. The application of these principles has resulted in increased nodule formation and a correspondingly increased crop yield. It was found, further, that the development of the nodules was very sensitive to the presence of boron in the growth medium. If this element were absent the nodule was either poorly developed or entirely lacking, and in the former case the organisms failed to fix atmospheric nitrogen in appreciable quantities and became parasitic on the plant cells.

Attention was directed by Dr. O. Rosenheim and Prof. J. C. Drummond to a colour reaction for vitamin A. The reaction consists essentially in the development of a brilliant ultramarine colour when a dehydrating agent, such as arsenic chloride or trichloracetic acid, is added to an oil containing the vitamin. The colour is sufficiently permanent to permit of a colorimetric estimation of the relative amount of vitamin A present. The discovery that the intensity of the reaction runs parallel to the vitamin-A content of cod-liver oils and butter as tested by the usual method of biological assay brings the method at once into extreme prominence and utility. It is interesting to record that a colour reaction, though a different and transient one, is also given by the addition to cholesterol of any one of the dehydrating agents used in the detection and estimation of vitamin A, and that yet another colour is given by irradiated cholesterol. It will be remembered that vitamin A is found exclusively in the unsaponifiable fraction of cod-liver oil.

Dr. H. W. Dudley and Dr. Rosenheim showed some crystals of spermine phosphate. This substance, however, has been shown not to be specific to semen, but to be capable of isolation from almost all animal tissues. It has further been detected in yeast. Naturally a substance with such a wide distribution in animal tissues may well be suspected of performing some definite and important function. Its molecular formula has been shown to be $C_{10}H_{26}N_4$, but its structure has not yet been determined.

The results of some interesting tissue culture experiments were given by the Imperial Cancer Research Fund. It was demonstrated that fresh tissue—kidney in this instance—failed to grow until an extract of damaged tissue, preferably homologous, was added to the culture. Possibly an explanation of regeneration in the neighbourhood of damaged tissue may lie hidden in this experimental fact. No differentiation in structure, however, occurs until the growth is inoculated with a pure culture of fibroblasts, and then it soon becomes possible to discern cubule formation in the formerly homogeneous cellular mass. The dependence of differentiation of structure on the presence of an adequate amount of growing connective tissue was further shown in a convincing manner in the case of epithelial tissue.

An electrical stethoscope exhibited by the International Western Electric Company should prove of great value for diagnostic and teaching purposes. On the one hand, by making use of electrical filters, waves of certain frequencies can be excluded or retained at will, thus making it possible to concentrate on a particular element in the sound, and on the other, a means is presented by which a large number of persons, up to 600, can listen simultaneously to an individual patient.

In addition, many other demonstrations and exhibits of less obvious bearing on the medical sciences served to make the evening one of extreme interest and lasting instruction.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Accidents in Vienna.

FOR the past 15 years there has existed in our city a special accident ward, which is really simply a surgical clinic for accident cases. It is managed by both surgical clinics of the General Hospital (Prof. Eiselsberg and Prof. Hochenegg), and the clinics have now published a report of the work done in this ward since its inception. In the preface Prof. Eiselsberg declares that the "accident service" in Vienna has attained a degree of fitness which makes it a model for all other places of a similar position. At any hour of the day or night a group of surgeons and nurses is always prepared to deal with cases of injury brought to the hospital, mostly by the street ambulances. All the modern and most up-to-date appliances are in daily use: portable X ray outfits, apparatus for transfusion of blood, anæsthesia apparatus, and so forth. As regards the results obtained, it may be stated that within the period mentioned above 24 cases of injury of the heart have been operated upon, 16 stab-wound cases, and 8 gunshot-wound cases, of which 6 of the former were saved and 4 of the latter. In 168 cases laparotomy had to be performed on account of injuries to the abdomen. A remarkable lesson is taught by the figures pertaining to the accidents caused by the traffic. The increase of the city life, of the number of vehicles, the ever-increasing employment of inexperienced workers at machines in factories has more than trebled the number of injuries in ten years; whilst the deterioration of public morals, the disappearance of the sense of responsibility, the mental instability ascribed to the war, to alcohol, and to poverty has also contributed largely towards the increase of injuries. Alcohol especially is a potent danger. In 1913 only 20 cases due to liquor were brought to the ward; in 1924, in the first ten months, the number was over 100. Motor-cars have increased in ten years by 25 per cent. only in Vienna, but the accidents caused by them have gone up by 500 per cent.! This compares very unfavourably with the tramcars, by which means over 458 millions were transported in one year with only 87 accidents; and even this figure is hardly higher than ten years ago, with a much smaller number of passengers then. The effect of alcohol is easily discernible in the sudden rise of cases on Sunday nights and Saturdays, when the week's wages are dissolved in this dangerous liquid.

Injury to the Fœtus Caused by X Rays.

Prof. J. Zappert demonstrated recently, at a meeting of the Vienna Medical Society, a baby with peculiar features. The weight of the baby was under 2 kg. at birth and at 7 weeks it was 2½ kg., the body-length being 50 cm. At the age of 7 months it weighed only 4½ kg., was very quiet, and showed a decided lack of intelligence, marked microcephalic appearance and some degree of mongolism. The right eye was very malformed, the left small, but capable of seeing. This condition of mongoloid idiocy has been noted in three cases (observed by Abels, Aschenheim, and Zappert) where the mothers had been treated with X rays during their pregnancy. The mother of the demonstrated patient, a woman of 23 years, who had suffered since girlhood from dysmenorrhœa, was irradiated on Dec. 18th, 1923, for the first time, and again eight days later (receiving 6 units of Holzknecht). Four weeks later she was found to be pregnant, and the child was born July 15th, 1924. In the other cases recorded elsewhere, the symptoms of microphthalmia and microcephaly were also combined. Although cases are known where pregnant women have been exposed to X rays without any resulting injury to the fœtus, experiments on animals have shown that irradiation does cause sterility or "unviable" offspring. Artificial abortion in human beings could not be obtained, however, by these means. As regards the mechanism of the injury, it must be noted that the exposure to the X rays of the mother in Prof. Zappert's case took place just at the time when the anterior part of the encephalon and the ophthalmic (optic) part are formed. Furthermore, experiments conducted by American workers have shown that certain chromatin bodies are especially liable to injury by X rays, such as the eyes and extremities. In the discussion following the demonstration it was agreed that at present the medical profession was not prepared to employ X rays on the ovary or uterus where pregnancy was assumed. Small myomata can be dealt with otherwise, and severe hæmorrhages can be controlled by irradiation of the liver, spleen, or hypophysis.

The Cause of Death in Injuries of the Skull.

Deductions from 69 fatal injuries to the head, investigated very thoroughly from the clinical and anatomical standpoint, were presented by Prof. Meixner to the Surgical Society of Vienna recently. He said that commotio cerebri played a very small part as the cause of death in these cases. In every case gross injuries of the brain substance or increased pressure by hæmorrhage was observed. In 12 per cent. of the cases only were contusions of the brain absent, but these contusions were not negligible conditions, as they were often ultimately responsible for the fatal issue. Even where death occurred within the first hour after injury commotio cerebri was not the real cause of death. Here the rapid loss of blood—sometimes the quantity was enormous—was chiefly responsible. Furthermore, in crushing injuries of the skull the destruction of the vital centres accounted for rapid death. But in over 50 per cent. of the fatal cases where death occurred more than an hour post trauma, and where a blunt instrument had inflicted the wound, the bruises to the cortex were the responsible factor. Protracted bleeding under the dura mater, in some instances also extending deeply into the brain substance, were the outcome of such injury, and in some cases inflammatory swelling of the brain followed. Hæmorrhage on the outside of the dura mater was much rarer and caused death more rapidly. The appearance of symptoms in hæmorrhage underneath the dura were very rapid, but death resulted much later. Changes and variations of symptoms were mostly due to multiple contusions. In a few cases only, where the decursus morbi was protracted, the immediate cause of death was not quite so clear; it seemed, he said, that here multiple changes were responsible. Serous meningitis, which was often suspected, had never been observed by Prof. Meixner in the post-mortem examination of such cases. He pointed out that contusion of the brain must not be confused with increased intracranial pressure. Contusion was an injury to the tissues, increased pressure a symptom, the contusion being the cause of the pressure. The expression "commotio" cerebri was generally used, whereas it should be "contusio" cerebri where protracted cranial conditions were meant. Fracture of the skull was generally accompanied by gross lesions, and the ultimate results in surviving cases should be regarded, he said, from the view not only of commotio but also of contusio cerebri.

The Biology of the Cancer Cell and Insulin.

Dr. Silberstein recently read a paper before the Gesellschaft der Aerzte, in which he discussed the problem of the biology of cancer. Warburg had already found, he stated, that cancer tissue produced 70–90 per cent. more lactic acid from dextrose than normal tissue. In collaboration with Dr. Revez and Dr. Freud the speaker had investigated the lactic-acid metabolism of cancerous animals. They did not find an increased output of lactic acid, perhaps because the excess was used up by the cells of the liver and by the muscles. (Prof. A. V. Hill's observations.) Animals in the pre-cancerous stage (subjected to painting with tar and injected with tumour tissue) had the same respiratory quotient as fasting animals. Feeding with carbohydrates did not affect this quotient in cancerous mice, but animals in the pre-cancerous stage were much more susceptible to insulin injections than healthy ones. Heated insulin was less active than in the cold state. After injection the pre-cancerous animals were hypersensitive to insulin for several days, whilst animals with fully-developed tumours could stand 30 to 50-fold normal doses of insulin, and the tumours exhibited a markedly slower rate of growth. The rate of growth increased when insulin was discontinued. If, soon after the injection of tumour masses, large doses of insulin were employed constantly, a large percentage of the animals remained free from cancer. Dr. Silberstein therefore urged clinicians to give insulin freely to the inoperable cancer cases, and to give a fair trial to this method, as the animal experiments gave such uniformly favourable results.

(From our own Correspondent.)

The Dual Nature of Cardiac Automatism.

In a thesis presented before the Academy of Medicine Dr. E. Donzelot criticised the conception of the single cardiac stimulus, transmitted from the auricles to the ventricles by conduction. This conception is based on two premises—first, the clinical evidence of a fixed relationship in the action of the auricles and the ventricles, and second, the experimental evidence which rests on the results of ligature, section, or compression of the auriculo-ventricular bundle, results which have further confirmed certain pathological observations. On the basis of several clinical observations, Dr. Donzelot holds that the cardiac cycle is governed by a double stimulus, auricular on the one hand and ventricular on the other. The auricular stimulus, which is apparently elaborated or centralised by the node of Keith and Flack, is of secondary importance only. The auricle is, effectually, only a blood reservoir whose periodic contractions are merely a security for the ventricle and not a necessity. The best proof of this lies in the finding that the function of the heart is adequate when the contraction of the auricles is absent or is seriously disturbed. The ventricular stimulus, elaborated or centralised by the node of Tawara, is, on the contrary, of prime importance. It is this stimulus which supplies, through the ventricular systole, the blood distribution throughout the body; any derangement of this stimulus is of importance and its absence is equivalent to a total cessation of the circulation. This view of a double cardiac stimulus modifies, by simplification, the general conception of arrythmias, and ought to open up a new line of research in ætiology and therapeusis of heart troubles.

Native Medical Service in French Colonial Africa.

French possessions in Africa cannot be made to yield of their best unless there is an adequate personnel to develop them. As far as medicine is concerned, the personnel is scanty and scattered, as was demonstrated to the Academy of Medicine recently by Prof. Emile Brumpt and Dr. Joyeux. The only method of improving the existing conditions, they held, was to develop the native medical service. Unfortunately, the number of doctors is negligible in comparison with the vast extent of French occidental and equatorial Africa. This number might be considerably augmented if the colony, in its own interests, were to offer to French doctors prospects in which adequate remuneration was made for a life work carried out far from la patrie, under difficult conditions. But it does not do so, for the French African colonies treat their doctors in very niggardly fashion, whereas neighbouring foreign colonies act much more generously towards their medical men. Young French doctors go willingly to Indo-China or to the Belgian Congo, but show little enthusiasm for occidental or equatorial Africa. The speakers said that more attention ought to be paid to this aspect of colonial development; the war and the present economic crisis had shown only too clearly the importance of medical service in the colonies.

How to Judge the Acoustics of a Hall.

At the Academy of Medicine Dr. Marage has been giving some practical advice on how to judge the acoustic properties of a hall, if these have not been explained beforehand to the singer or orator. The judgment is based on the following points: first in an empty hall, judged by the eye; a large hall, with a very high roof and side walls not furnished with boxes, and having somewhat concave background to the platform, is probably too resonant and will give echoes. A hall without galleries, with a low roof covered with a curtain, and in shape longer than it is broad, has probably very poor acoustic properties and the voice will carry badly. To judge by the ear:

A vowel sound is sustained in speaking or singing for about three seconds, and the performer can himself hear the resonance, if it lasts too long. When the hall is full of people, it must be remembered that the audience have a great absorptive power as regards sound, and resonance diminishes in proportion to the size of the audience. If, in speaking or singing, the performer can hear his own voice resonating slightly, then he may be assured that he is audible to all. If, in spite of efforts, no resonance is heard, then it is useless to force the voice, and the performer must address himself to the front rows of the auditorium. If one is aware of a strong resonance, the voice must be lowered to as deep a note as possible. If the attention of the audience flag—and the cause be not in the subject-matter of the performance—it must be remembered that the ear is more sensitive to high notes, and the performer should tune his voice to a higher pitch.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following are some of the health statistics of a group of districts of varying local government status for 1924 :—

Name of district.	Mid-year population (R.-G.).	Birth-rate.	Death-rates per 1000 of the population.				Death-rates per 1000 births.		
			All causes.	Tuberculosis.	Cancer.	Resp. diseases with influenza.	Neonatal mortality.	Infant mortality.	Maternal mort. from childbirth.
Reading C.B. ..	93,680	17·1	10·7	1·03	1·4	1·9	26	54	3·1
Bootle C.B. ..	83,130	23·4	11·6	1·40	0·9	2·7	34	99	5·1
Holland C.C. (Lincolnshire)	87,400	20·7	11·7	0·98	1·7	1·8	—	65	2·7
Watford B. ..	48,628	17·7	9·8	0·82	1·3	1·9	30	55	5·9
Stafford B. ..	28,730	15·6	9·7	1·20	1·1	1·8	38	73	8·9
Runcorn R.D. ..	29,370	14·9	9·9	1·09	1·1	1·3	—	46	6·8
Chelmsford R.D.	25,710	17·8	11·7	0·80	1·3	1·9	—	50	2·2

C.B., County borough. C.C., County council. B., Borough. R.D., Rural district.

Reading.

Dr. H. J. Milligan reports that of the total number of persons who died nearly half had passed their sixty-fifth birthday. The rapid fall in tuberculosis mortality has not been maintained, and Dr. Milligan thinks post-war conditions, such as housing shortage, unemployment, and the general uncertainty and anxiety are responsible. The loan of shelters continues to be of great service. The Voluntary Care Association finds difficulty in securing employment for tuberculous persons; employers are prejudiced, and there is also the difficulty in fixing hours of work and adequate pay. The association found there was no opening for window-cleaning, brush-making, and chopping firewood, but a few patients were found satisfactory jobs as gardeners, motor drivers, delivering parcels, night-watching, and so on.

The Reading Medical Society is a limited company, conducted by the medical practitioners to meet the requirements of the dependants of insured persons by means of weekly subscriptions and caters for the medical requirements of 10,000 persons. The Reading Dental Society provides similarly for dental requirements. Dr. Milligan is convinced that the lessening number of new cases at the V.D. clinic represents a real diminution in the prevalence of venereal disease. The Dellwood Maternity Home admitted 239 patients. The accommodation has been found inadequate. A separate pavilion is to be provided for the nursing staff, and isolation wards for severe or septic cases. Owing to an outbreak of pemphigus neonatorum, the home had to be closed during January of the present year. The housing shortage makes this home a necessity. Thus of the 239 cases admitted, 62 came from a one-room and 93 from a two-room home. The husbands of 43 applicants were unemployed. The average fee paid was £1 9*s.* per week, and the fee was remitted in 21 cases. The antenatal clinic was attended by 266 new cases, and of these 208 were awaiting admission to Dellwood. Housing conditions remain very unsatisfactory. "There is much overcrowding, and dwellings in a ruinous condition have to remain in occupation for lack of alternative accommodation."

The school report shows that medical inspection has now reached a stable form and that the numbers inspected annually slightly exceed one-third of the average attendance. Although there is a gradual improvement year by year, certain defects, such as errors of vision and enlarged tonsils and adenoids, occur in much the same proportion as formerly. Ionisation of ear discharges continues to give good results, and there was no recurrence of discharge in cases treated in 1923. Parents are becoming more alive to the need for greater care of the teeth of their children, but it is noted that there is still a considerable prejudice against having teeth filled and also ignorance of the fact that the six-year old molars are permanent teeth. Over 20 per cent. of the children examined at the routine medical inspections were classed as "under-nourished," but the increased proportion is only apparent, being due to the adoption of a definite standard which gets rid of the personal predilection of the examiners. All children 7 per cent. or more under the average weight for their height are considered "under-nourished," and as time goes on this standard will provide a reliable basis for comparison. An examination of boys and girls of 12 years of age for enlarged thyroid was carried out during the year. Only those children whose thyroids could be noticed by inspection without measurement or palpation were counted. Nine out of 413 boys and 34 out of 551 girls had some enlargement. The majority of the cases seen were very slight. The school medical service of Reading is very well equipped for dealing with all kinds of special cases and exceptional children.

Bootle.

Dr. F. T. H. Wood says housing is still the most pressing need. The hoped-for completion of a large number of houses did not materialise, and the population increased by 1500. Only three houses, instead of 100, were completed. The council houses erected during the last five years numbered 26, 76, 200, 0, and 3 respectively. It is hoped to make better progress during 1925. Dr. Wood cites instances of urgent cases coming to the knowledge of his department. Attention has been given to the cleanliness of the milk, and the results of the examination of the local and imported milks are anything but satisfactory. In four cases "the milk can be considered to be grossly contaminated." Out of 22 samples examined for tubercle, four were found to be infected. The regulations for milk-shops are to be enforced more strictly, with a view to restricting the sale of milk to properly equipped dairies. Although 14 of the 118 samples of milk were reported by the public analyst to be adulterated, the average amount of fat in the 118 samples was 3·71 per cent., and of non-fatty solids 8·76 per cent., to be compared with the presumptive standard of 3 per cent. and 8·5 per cent. fixed for genuine milk.

A severe type of scarlet fever prevailed in Bootle during 1924 with a case-fatality of 2·2 per cent. The Schick test was used in the case of 158 scarlet fever admissions, and indicated the diminishing susceptibility at the later age-periods. Thus 26 out 53 gave positive results under 5 years of age, 23 out of 61 at the 5-10 age-period, 7 out of 35 at 10-15 years, none out of 6 at 15-20 years, and none out of 3 at ages over 20. New probationer nurses are tested after engagement. Since this practice was adopted, four out of 14 have given positive reactions and have been treated with toxin-antitoxin.

The maternity home has not been fully used, and the standard fee of 6 guineas for a fortnight's nursing and maintenance has been reduced to 4 guineas since March, 1925. During last year 114 cases were admitted, and it was estimated that 44 additional cases could have been accommodated at an added cost of £55 only, for food, laundry, &c. For the last financial year the gross cost was £1497, and the cost to the rates (after deducting patients' contributions, £465, and Exchequer grant) was £516. Dr. Wood draws attention to the high infant mortality from respiratory disease and the need for health visitors concentrating on clothing and ventilation advice. He stresses the need for an increase of staff. The Council in January, 1924, decided to appoint an additional health visitor, in accordance with the wish of the Ministry, but subsequently rescinded their decision. The present staff is unable to give adequate attention to the "toddlers." At the present time a weekly infant consultation is held at each of the three centres maintained by the Bootle Health Society. As the average attendances during the fourth quarter of 1924 were 115, 117, and 107 respectively, the need for an increase in the number of consultation days is obvious.

Lincolnshire: Holland.

Dr. H. C. Jennings reports that an arrangement came into operation in April, 1924, by which county patients may use the V.D. clinics at Peterborough and Lincoln, and that over £80 was spent in paying the railway fares of such patients. In November a tuberculosis dispensary was opened at Spalding and this will meet a long-felt want in the southern portion of the county. Hitherto the county council have established no maternity and child welfare centres, but arrangements have been made for opening a centre at Long Sutton and for utilising centres at Spalding and Boston. Dr. Jennings draws attention to the fact that the infant mortality is higher in the rural than in the urban districts, and attributes this to the rural mothers working on the land, and leaving their babies "in charge of some old woman, who is paid a small sum of money for her trouble." A table shows that cancer has always caused a higher death-rate in the low-lying parts of Lincolnshire than in other parts of England and Wales, and the report contains a suggested leaflet for issue to the public. There are now no "bona-fide" midwives practising in the county, the last having retired in 1924; but there are several women practising midwifery illegally and owing to the wording of the Act it has hitherto not been possible to stop them. The greater part of the county area is without a public water-supply, and dependent on rain-water tanks, shallow wells, or surface water from rivers. The whole question will be reviewed in the report for 1925.

Watford.

Dr. Wm. J. Cox refers to the shortage of working-class houses and the consequent overcrowding. The present scheme for 250 new houses will be a "great help," but 1000 houses are needed to meet present difficulties. Four cases of encephalitis lethargica were notified, two cases being in one family. There was one death. In answer to an inquiry from the Ministry, particulars as to scarlet fever since 1892 have been got out. Dr. Cox thinks hospital isolation has diminished the prevalence and may have helped to develop a milder strain of the disease. Among the school-children goitre was found to be negligible in prevalence among boys, but about 5 per cent. of the girls showed obvious signs. None of the cases was sufficiently marked to cause any anxiety.

Stafford.

Dr. J. T. MacNab hopes, that, now the private builder, encouraged by subsidies, is again coming forward, fresh efforts will be made to provide houses for the poorer workers. A second health visitor has been appointed and more commodious premises secured for the "centre."

The new sewage disposal works are about to be put in hand and will bring about a much-needed improvement. Thirteen cases of encephalitis lethargica were notified, with two deaths at ages 70 and 43. The first two cases occurred in March and the last in December. Only two or three of the surviving 11 are free from after-effects and in two at least there is mental impairment.

Runcorn Rural District.

Dr. J. S. Manson reports a great increase in house building, but he is doubtful as to whether the type being built will afford accommodation for the lower-paid wage-earner. A report on the prevalence of scarlet fever during the last 32 years has been made to the Ministry. The main conclusion was that the disease had become milder, but that there was very little diminution in its incidence. Four out of 34 samples of milk examined for tubercle were found to be infected. An effort is being made to interest the producers in the production of clean milk. Runcorn is within the Manchester regional town-planning area, and sent representatives to an area conference on smoke abatement. A committee has been set up to formulate practical suggestions for submission to another conference later on.

Chelmsford Rural District.

Dr. John F. Macdonald says the shortage of house accommodation is still acute throughout the district. During the year the rural council for the first time appointed a veterinary surgeon to carry out a systematic inspection of all the dairy herds in the district. The report of the veterinary surgeon, Mr. J. Bishop Young, is given in full. The cows inspected numbered 3939 in 166 herds, and Dr. Macdonald tells us that this single inspection resulted in the elimination of 33 dairy cows from the milking herds. Mr. Young's report contains much advice which should be valuable to the dairy-farmers of the district. For example, he emphasises the importance of milk-recording, and he cannot understand why, in the interests of clean milk production, manure is not removed at once instead of being piled close to the cowshed.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED MAY 9TH, 1925.

Notifications.—The following cases of infectious disease were notified during the week, namely:—Small-pox, 162; scarlet fever, 1691; diphtheria, 855; enteric fever, 60; pneumonia, 1027; puerperal fever, 47; cerebro-spinal fever, 13; acute poliomyelitis, 6; encephalitis lethargica, 80; dysentery, 4; ophthalmia neonatorum, 103. There were no cases of cholera, plague, or typhus fever notified during the week. The number of small-pox cases showed a decrease of 14 from the number for the preceding week. Five cases were notified from the County of London (Bethnal Green 4, Lambeth 1); 60 from Derbyshire (Derby C.B. 43, Alvaston and Boulton 1, Chesterfield 4, Clay Cross 2, Chesterfield R.D. 10); 11 from the county of Durham (Brandon and Byshottles 2, Hartlepool 1, Leadgate 2, Whickham 3, Chester-le-Street R.D. 1, Easington R.D. 1, Lanchester R.D. 1); 1 from Lancashire (Audenshaw); 2 from Leicestershire (Leicester C.B. 1, Hinckley R.D. 1); 1 from Lincolnshire, parts of Lindsey (Gainsborough); 8 from Northamptonshire (Kettering); 25 from Northumberland (Newcastle C.B. 3, Ashington 7, Bedlingstonshire 11, Newburn 1, Prudhoe 3); 13 from Notts (Nottingham C.B. 1, Hucknall 2, Kirkby-in-Ashfield 1, Mansfield 1, Mansfield Woodhouse 8); 6 from Warwickshire (Coventry C.B. 3, Nuneaton 3); 22 from Yorks, North Riding (Middlesbrough C.B.); and 8 from Yorks, West Riding (Rotherham C.B. 3, Adwick-le-Street 4, Maltby 1).

Deaths.—One death from small-pox belonging to Chesterfield was registered during the week. In the aggregate of great towns, including London, there were 2 deaths from enteric fever, 86 from measles, 11 from scarlet fever, 118 from whooping-cough, 31 from diphtheria, and 68 from influenza, as compared with 100, 139, 162, and 221 in the four preceding weeks. In London itself the deaths from influenza numbered 12, from whooping-cough 27, and from diphtheria 13.

THE DEATH REGISTERED AS FROM SMALL-POX AT CHESTERFIELD.

One death from small-pox belonging to Chesterfield was registered during the week ended May 9th. Dr. R. P. Garrow, medical officer of health for Chesterfield, informs us that the death so registered was that of a woman of 60 years in the last stages of chronic nephritis, with albuminuria, ascites, watery bronchial catarrh, and feeble action of the heart. He states that the attack of small-pox may or may not have accelerated her death. The attack was of the ordinary mild form prevalent in the district.

THE BATEMAN APPEAL.

As already explained in THE LANCET, it has been felt that material assistance ought to be offered to Dr. Bateman to meet the legal expenses of his recent successful appeal against conviction and to make good the deficiency in his professional income. Accordingly, the Bateman Fund has been opened and lists of contributions have appeared in recent issues. We have received additional contributions as follows :—

	£	*s.*	*d.*
Already received and acknowledged ..	446	18	6
Dr. J. Fawcett	2	2	0
Dr. F. Savery	2	0	0
" Anonymous "	2	0	0
Dr. J. B. Hurry	1	1	0
Dr. J. P. Westrup	0	10	6
" Abroad "	0	10	0
	455	2	0

Remittances should be forwarded to the Manager of THE LANCET, 423, Strand, W.C. 2, and made payable to the " Bateman Fund Account."

The Services.

ROYAL NAVAL VOLUNTEER RESERVE.

Surg. Cdr. H. L. Murray has been awarded the Royal Naval Volunteer Reserve Officers' Decoration.

ROYAL ARMY MEDICAL CORPS.

Maj.-Gen. W. H. S. Nickerson, late R.A.M.C., is appointed Hon. Surg. to the King, vice Maj.-Gen. T. W. Gibbard, late R.A.M.C. (ret.).

Capt. J. H. C. Walker is granted the temp. rank of Maj. whilst empld. as a Dep. Asst. Dir. of Pathology.

Capt. J. J. Molyneaux, half pay list, late R.A.M.C., retires on account of ill-health.

Lt. J. L. Howells relinquishes the rank of Lt. on enlistment into the Supplementary Res.

Lt. (on prob.) T. J. M. Dodd is secd. under the provisions of Art. 197, Royal Warrant for Pay and Promotion.

RESERVE OF OFFICERS.

Maj.-Gen. E. M. Pilcher, late R.A.M.C., having attained the age-limit of liability to recall, ceases to belong to the Res. of Off.

TERRITORIAL ARMY.

Maj. (Prov.) C. Douglas is confirmed in his rank.

Capt. W. S. Martin, R.A.M.C., to be Divisional Adjt. 47th (2nd Lond.) Div. and School of Instruction, vice Maj. W. P. Croker, R.A.M.C.

TERRITORIAL ARMY RESERVE OF OFFICERS.

Lt.-Col. D. G. Rice-Oxley, from Active List, to be Lt.-Col.

ROYAL AIR FORCE.

Flight Lt. (Hon. Squadron Leader) W. R. Kemp relinquishes his temporary commission on ceasing to be employed and is permitted to retain the rank of Flight Lt.

INDIAN MEDICAL SERVICE.

The King has approved the retirement of Lt.-Col. A. T. Gage.

Correspondence.

"Audi alteram partem."

THE BATEMAN APPEAL.

To the Editor of THE LANCET.

SIR,—Generous donors may send larger sums. If, however, the majority of registered medical men each sent a small sum (such as the P.O. for 10*s.* which I now enclose) it would assure Dr. Bateman of our widespread sympathy, and result in a sufficiency to meet the needs.

I am, Sir, yours faithfully,

Mussoorie, April 29th, 1925. ABROAD.

POST-GRADUATE TEACHING IN MIDWIFERY.

To the Editor of THE LANCET.

SIR,—As obstetrics and post-graduate work are both under discussion at present, it appears to me that the experiences of a post-graduate may be of service to those responsible for the organisation of such work. After having practised for a number of years in India I recently returned to this country with the object of taking up research work in connexion with maternal morbidity in India, and with this end in view I was anxious to obtain the best post-graduate course in obstetrics available.

I went first to the headquarters of a post-graduate association in London, and when I had explained what I wanted the clerk said : " If it is obstetrics you wish, I am sorry we can do nothing for you. It would not be worth your while to pay a fee." I then looked round the London hospitals. Some of the obstetricians connected with them were extremely kind and invited me to attend their clinics, which I did, but it was on the understanding, of course, that the students had the first right to the clinical material, and a casual visitor felt a delicacy about drawing the attention of the staff to subjects of interest which would be of little importance to students preparing for examination.

I then looked beyond London and heard of a post-graduate course in obstetrics in Edinburgh, but this only took place during the summer vacation, a time not suitable for me. I knew that post-graduates were catered for in Dublin, and therefore I entered as a post-graduate at the Rotunda Hospital for a month.

The Rotunda Hospital has a great deal to fit it for a first-class post-graduate school. It attends, in its extern and intern departments, over 4000 labour cases annually. It has ample accommodation for students and an establishment which enables them to board at reasonable rates with a fair degree of comfort. As regards obstetrics, it has deservedly a world-wide reputation. The applications from students and post-graduates are very numerous. It was, therefore, disappointing to find that more attention was not given to teaching. Let me briefly describe the opportunities offered. Students and post-graduates, 40 to 50 in number, were grouped together, and there were in addition 20 to 30 probationer nurses attending lectures and deliveries. Three times a week at 10 A.M. the Master visited the cases in the waiting ward and then delivered a lecture on midwifery. These lectures were most interesting, but no effort was made to make them useful to post-graduates. The whole subject of obstetrics was gone through in rotation, and although the matter was, of course, entirely up-to-date, it might quite happen that the post-graduate did not, during a month, hear anything he had not known five or ten years before ; that is to say, none of the subjects on which recent work has been done might happen to have their turn. A short clinic on gynæcological out-patients followed, more useful to the student than to the post-graduate, and the work finished at 12 or shortly after. On two days a week operations might be attended at 10 A.M. On these days the post-graduate might, if he liked, attend a half-hour lecture on elementary midwifery given by one of the assistant masters. This finished the work. There were no visits to the wards (other than the waiting room), and no opportunity to follow up the cases seen in the labour room and theatre. True, it was stated in the rules that the students might visit the wards, but those who did so frequently found they could not be admitted owing to the nurses' work or other matters. A few enthusiastic spirits visited the waiting ward each evening to see the new cases. There were eight beds in the ward, seldom all occupied, and it was fortunate for the patients that the bulk of the students did not attend. Little antenatal work appeared to be done, and that the students could not attend as it was carried on at the same hour as the Master's lecture.

There was no library other than half-a-dozen antiquated volumes, no periodicals available, no reading room where silence was observed, no notices of clinics or lectures elsewhere which the post-graduates might attend. The medical students were kept fairly busy attending and visiting cases in the district, and as a rule only remained two or three weeks, but the post-graduates (who took no normal cases) often remained as long as six months, which period was required for admission to the L.M. examination. It seemed to be the common opinion that one month's careful reading of the Master's book was sufficient preparation for this examination, which was purely oral, and that the remaining five months could be spent in amusement. The atmosphere of the common mess-room was not conducive to study.

Deliveries, of course, took place at any time. But owing to the large numbers of students, only a few could really see what was being done. All except the most important obstetric operations were done by one of the assistant masters. Most of the post-graduates were profoundly disappointed at not getting any operative experience even after months of residence. There were two types of post-graduates, the first, and by far the larger, being newly qualified practitioners especially anxious to gain practical knowledge, the second being older practitioners, frequently from abroad, who wished to learn the latest obstetric methods. The attitude of the hospital authorities seemed to be that post-graduates were tolerated and were left to pick up what information they could.

I feel I owe an apology to that distinguished institution, whose work I respect and admire, for these criticisms, but it appears to me that they illustrate the principle that post-graduates cannot be taught with students, and that a different organisation altogether is required, at least for those older practitioners who do not need experience but who wish to learn the latest methods in the shortest possible time and are willing to pay to do so. If such a course could be arranged with the coöperation of several of the lying-in hospitals in London, it need interfere little with the teaching of students. It would be necessary to arrange for lectures, visits to lying-in wards (which should include not only clinical instruction, but instruction in nursing organisation and newer hospital construction), attendances at antenatal clinics, demonstrations on newer methods of examination (including bacteriological, X rays, &c.), visits to special institutions in connexion with infant welfare, venereal disease, &c., and attendance at selected operations. It would be essential that the teachers should all be experts in their own subjects.

I am, Sir, yours faithfully,

May 8th, 1925. MARGARET I. BALFOUR.

THE ALLEVIATION OF CHRONIC PROGRESSIVE DEAFNESS.

To the Editor of THE LANCET.

SIR,—We have read with interest and pleasure Mr. G. C. Cathcart's paper on the use of the Zund-Burguet electrophonoide in chronic progressive deafness. Indeed, the pleasure is enhanced by the fact that, in spite of the discouraging reports of other otologists, we had determined to investigate the value of the Zund-Burguet apparatus for ourselves. Our results have so far justified us, and they appear to be quite equal to those of Mr. Cathcart, although we have not yet used the machine sufficiently long to enable us to speak decidedly as to permanence or otherwise of the improvement effected. We agree with Mr. Cathcart that tinnitus is the first symptom to yield to the method, improvement of hearing occurring later. In one case of "hysterical" deafness the hearing became worse; this appears to us to be strong evidence against any suggestion that the treatment acts by any "psychic effect." We attach great importance to the concurrent use of a vibrator, to which we are inclined to attribute the improvement in general health which we have, in common with Mr. Cathcart, noted in nearly every case.

We are, Sir, yours faithfully,
MACLEOD YEARSLEY, F.R.C.S.
CHARLES BENEY, M.B. Camb., M.R.C.S.

Wimpole-street, W., May 12th, 1925.

SECONDARY SARCOMA OF THE PANCREAS.

To the Editor of THE LANCET.

SIR,—In your issue of May 9th Dr. James Crooks records a case with the above description. There are many other such cases scattered in the columns of medical journals and Proceedings of societies. Some of these, perhaps half the total number, are described as sarcomas; the other half are to be found under such titles as chloroma or leukæmia. Where the former title is used, the original site of the sarcoma seems to be arrived at by a process closely analogous to guess-work, and in the case which you now record there is, alas, more than a little evidence of this same process.

Why should the ovaries be picked upon as the primary site of the disease? The disposition of the secondary growths, so-called, in such regions as the orbits hardly suggests origin in the ovary any more strongly than origin in the pancreas or thymus. If it be held that the secondary growths were disseminated by the blood-stream, we have still no particular reason to suspect the ovaries. Perhaps we may be told what clinical, anatomical, or pathological feature of this case justified the conclusion that the primary growth was in the ovaries.

Putting aside for the moment the question of sarcoma, one cannot help noting that there are many features in this case which suggest leukæmia as a more likely diagnosis. The blood condition is not typical of what the text-books used to denominate leukæmia, but it is much less typical of anything like sarcoma, and can be many times paralleled from the records of cases in which the blood was at some other stage frankly leukæmic.

There is another feature which might have aroused attention, and this is recorded in the following form, "Pressure over the shafts of the femora caused pain." One assumes that this feature was rather striking, or it would not have earned mention. What was it due to? One is accustomed to find it recorded in cases of leukæmia and supposes (rather vaguely) that hyperactivity of the bone-marrow and absorption of bone are to blame. But one may doubt if bilateral tenderness has ever before been recorded in a case of primary sarcoma of the ovaries. Another bilateral feature is afforded by the growths in the orbits. There is no evidence to tell us whether these originated in the periosteum or, as is more likely perhaps, in the connective tissues of the lacrymal glands, but a reference to the literature of Mickulicz's disease would doubtless show that this feature was more frequent in leukæmia than in sarcoma of the ovaries.

I admit that the report on the microscopy of the liver troubles me. There is so usually "round-celled infiltration" in leukæmia that its absence is curious. Perhaps a further search of the sections might reveal this, or perhaps the only section taken happened to be in a spot free from such change. However that may be, one may perhaps plead with authors who may contemplate the publication of cases of sarcoma with curious blood pictures that they will relate one to the other in some coherent manner.

I am, Sir, yours faithfully,

Sevenoaks, Kent, May 13th, 1925. GORDON WARD.

MR. GREIFFENHAGEN'S PORTRAIT OF SIR DONALD MACALISTER IN THE ROYAL ACADEMY.

To the Editor of THE LANCET.

SIR,—The reference to this portrait made in THE LANCET of May 9th was not quite accurate, but I fear that the correction made this week confounds the confusion. The portrait now hanging in Burlington House is that presented to Lady MacAlister, and is taken from the one painted by Mr. Greiffenhagen for the General Medical Council.

I am, Sir, yours faithfully,

May 19th, 1925. DONALD MACALISTER.

CLEAN MILK IN HOSPITALS.

To the Editor of THE LANCET.

SIR,—On p. 1064 of your issue of May 16th you quote Dr. Chalmers Watson as having ascertained that practically none of the larger hospitals are using Grade A tuberculin-tested milk at the present time. I would like to point out that we have been using Grade A tuberculin-tested milk entirely since May, 1923, for both the isolation hospital and sanatorium in Leicester, as well as the staff resident here. We deal with infectious diseases and all forms of tuberculosis, both pulmonary and surgical, at this institution. The number of beds for patients here is 340, and the number of our resident nursing staff is 88, a combined total of 428. Even our cases of small-pox get Grade A tuberculin-tested milk! Our average daily consumption of milk is 50 gallons. The milk is bacteriologically and qualitatively examined by us, about once a week in summer and twice a month in the winter, in order to ascertain if it is up to standard. During the past two years that we have taken this milk we have been very satisfied with it, and I wonder, like Dr. Chalmers Watson, that more institutions, and especially local authorities, do not go in for it. I do not know if this institution was the first to use Grade A tuberculin-tested, but I think it certainly was one of them, if not the first to do so.

I am, Sir, yours faithfully,

F. A. E. SILCOCK, M.B., D.P.H.,
Medical Superintendent, Isolation Hospital
May 16th, 1925. and Sanatorium, Leicester.

WOMEN'S WAR MEMORIAL IN YORK MINSTER.

To the Editor of THE LANCET.

SIR,—The Five Sisters Window in York Minster, which has been restored by women of the Empire in memory of women who gave their lives in the war, is to be unveiled on June 24th at 3 o'clock in the afternoon by the Duchess of York. Also an oak screen has been placed in the Minster with the names of the women to be commemorated. There are several women doctors on the roll of honour and it is very desirable that as many of their colleagues as possible should pay tribute to their memory on this occasion, whether they did war work or not.

As all representatives of war workers are to wear uniform it is requested that medical women who are present shall wear academic dress. All who have decorations should wear them. During the time of the ceremony at the Minster, memorial services are to be held throughout the Empire—e.g., in Australia, Canada, New Zealand. The railway companies are to issue special terms—i.e., return fare at one and a third the usual single fare, or for parties of 12, return fare at the price of the usual single fare.

I have been asked by the promoters of the Memorial to organise the medical deputation, and as it is impossible to get into touch with all by letter, I am writing to ask if you would kindly make the matter known. Applications to be present should be sent to the Hon. Secretaries, Women's War Memorial, Assembly Rooms, York, as early as possible.

I am, Sir, yours faithfully,

York, May 16th, 1925. LOUISE FRASER, M.D. Lond.

Obituary.

HOWARD HENRY TOOTH, C.B., C.M.G., M.D. CAMB., F.R.C.P. LOND.,

CONSULTING PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITAL, THE NATIONAL HOSPITAL FOR PARALYSED AND EPILEPTIC, AND THE METROPOLITAN HOSPITAL.

Dr. Howard Henry Tooth, who died on May 13th at Hadleigh, Suffolk, at the age of 69, was well known, both as a physician with a bent towards neurology, and as an administrator. Born in 1856 at Brighton, he was educated at Rugby and entered St. John's College, Cambridge, in 1874. Six years later he graduated in medicine from St. Bartholomew's Hospital, to which he then became casualty physician. Later he was, in succession, demonstrator in physiology, medical tutor, and demonstrator of morbid anatomy; in 1897 he was appointed assistant physician, becoming in due course full physician in 1906 until 1921, when he retired on attaining the age-limit. For many years he lectured at the hospital on diseases of the nervous system, and at the weekly "medical consultations" his opinion on all obscure nervous cases always carried weight. Becoming a Fellow of the Royal College of Physicians of London in 1888, he gave the Goulstonian lectures in the following year. In these he dealt with secondary degenerations of the spinal cord, basing his conclusions on observations made at the National Hospital for the Paralysed and Epileptic, where he was at that time assistant physician. The lectures were noteworthy for the remarkable knowledge they displayed of the minuter anatomy and physiology of the central nervous system. Dr. Tooth became Councillor of the College from 1906 to 1908 and was a Censor in 1913–14. He also examined in medicine at Cambridge and Durham universities. His presidential address at the Neurological Section of the Royal Society of Medicine in 1912 was concerned with intracranial tumours, of which he had then collected 500 examples, his experience leading him to take a very cautious view of operative intervention. This was a valuable research whose lessons remain sound to-day. It was an authoritative communication on a difficult subject; it was the outcome of a characteristically close investigation of all the available records, and represented two years of close work.

When the South African war broke out Tooth offered his services and was appointed physician to the Portland Hospital, where his work gained him the C.M.G. Before that he had served on a committee for the reorganisation of the Army Medical Service. On returning from South Africa he maintained his interest in the University of London O.T.C. and took an active part in the organisation of the London hospitals on a territorial basis. Early in the Great War he was placed in command of the 1st London General Hospital at Camberwell, of which he became the historian, afterwards going overseas as consulting physician with the rank of colonel and doing good work both at Malta and at the Italian front. He was three times mentioned in despatches and in 1918 was awarded the C.B. The University of Malta conferred upon him the M.D. hon. caus. Tooth was also a good friend to the rank and file of the R.A.M.C., and for several years before his death was chairman of the Army and Navy Male Nurses Association to provide opportunities for civilian nursing to members of the Corps after leaving the Service.

Dr. Tooth was twice married: in 1881 to Mary Beatrice, daughter of the late Edward Price, by whom he had a daughter; and in 1907 to Helen Katherine, daughter of the Rev. Charles Chilver, of Midhurst, by whom he had a daughter and two sons, one of whom will follow his father's profession. Three months ago Dr. Tooth had a cerebral hæmorrhage while driving his car and did not recover the use of his limbs, although his mind remained clear to the last. His death is deeply regretted by all with whom he had come into relation, and sympathy goes out to his widow and family.

Sir Anthony Bowlby writes: "The characteristic qualities of Howard Tooth's work were the extraordinary patience and thoroughness with which he investigated all his cases and the sympathy and desire to help which were always in evidence. It was these qualities which made him so successful both as a general physician and as a consultant in nervous disease. At St. Bartholomew's Hospital he was an ideal colleague and one who always kept in mind what was best for the hospital and school. Twenty or more years ago, when the hospital entered upon its career of expansion, it was Tooth who acted as secretary to the Medical Council and served on every one of the various subcommittees and in numberless consultations with the hospital governors. As a teacher in the medical school he was as careful and conscientious as in everything that he did. He loved to be with young people and his pupils quickly realised that he was a lenient critic of their clinical efforts and their guide and friend in the out-patient room or the medical ward.

"A very important part of Tooth's life work was his association with the Army, for the beginning of which I own myself mainly responsible. When in October, 1899, I was asked to take charge of the Portland Hospital, I invited Tooth to come with me. His services were in constant demand by the Army Medical Department during the campaign, when for a long time he was the only consulting physician in South Africa. He thoroughly enjoyed the open-air life and the constant sunshine of the veld, and proved *persona grata* to the personnel of the R.A.M.C.

"I knew Tooth from his arrival as a student at the hospital, and while he made many friends I never knew him make a real enemy. For many years he was an enthusiastic bicyclist and on various holidays rode from London to the North of Scotland and back. He was also a keen fisherman. At home, when he was not otherwise busied, he would be found in his carpenter's shop, for he was a most skilful worker both in wood and metal, and I always felt that with such excellent hands he ought to have been a surgeon. He continued to lead an active life until past middle age, when he became subject to abdominal troubles, although he went successfully through two operations.

"After leaving London for the country, he accepted an appointment at a clinic for nervous diseases under the Pensions Ministry, and took the keenest interest in this work until shortly before his death. The fact was that he was never quite happy unless he was occupied, and from first to last his life was a very busy and a very useful one."

CECIL CHRISTOPHERSON, M.R.C.S. Eng.

The death occurred in a nursing home at Bexhill, on May 11th, of Dr. Cecil Christopherson, who was one of the best-known practitioners in Hastings. He was born at Blackheath in 1862, and was educated at Marlborough College. He studied medicine at St. Bartholomew's Hospital, and qualified L.S.A. in 1885, obtaining the M.R.C.S. Eng. and the L.R.C.P. Lond. in the following year. Following an appointment at the North-West London Hospital, Dr. Christopherson went into general practice in Hastings. In 1893 he was appointed assistant house surgeon at the Royal East Sussex Hospital, and served for 30 years on the staff, until ill-health forced him to retire in the winter of 1923, when he became consultant surgeon. On his retirement the governors presented him with a handsome testimonial, the monetary part of which he returned as a donation to the hospital. He was one of the originators and founders of the Hospital Benevolent Fund for East Sussex. During the war he was on the medical staff of Netley Hospital. He was at one time President of the East Sussex Medico-Chirurgical Society, and in 1915 was placed on the Commission of the Peace for the borough of Hastings. He was a staunch Churchman and a Freemason. He leaves a widow and two sons.

Medical News.

Royal Colleges of Physicians of London and Surgeons of England.—As the result of the Final Examination in Medicine, Surgery, and Midwifery, held from April 14th to May 9th, the following candidates were approved in the under-mentioned subjects, but are not eligible for diplomas:—

Medicine.—J. S. Alman, Berlin; A. A. Anderson, Western Univ., Canada, and London; S. A. Antoun, Birmingham; L. Appell, Charing Cross; E. Bacon, St. Bart.'s; W. Baker, Leeds; C. M. Barker, Univ. Coll.; Jane G. Bevan, Westminster; S. S. Bhatnagar, Middlesex; C. A. Birch, Liverpool; H. M. Birch, Adelaide and London; F. T. Birkinshaw, Univ. Coll.; V. H. Brink, London; Theodora Brookes and Olive K. Burnett, Royal Free; Isabella M. G. Butler, Univ. Coll.; F. Carroll, St. Mary's; R. Cohen, Leeds; S. M. Coleman, St. Bart.'s; G. W. Curtis, Birmingham; H. G. Davies, Guy's; Hilda C. Dean, Charing Cross; G. Dietrich, St. Bart.'s; Dorothy Durance, Royal Free; W. G. P. Dyson, Manchester; R. G. Eastwood, Leeds; A. K. H. El Shurbagi, St. Thomas's; H. E. Filmer, Guy's; J. W. Fisher, St. Mary's; L. O. F. Fysh, London; J. Gabe, Westminster; E. H. Glynn, Liverpool; T. R. Goddard, Univ. Coll.; J. Gore, Birmingham; M. Gottfried, St. Mary's; M. J. Harker, St. Bart.'s; J. W. Hart, Univ. Coll.; Dorothy G. Hervey, Birmingham; A. B. Hewlett, King's Coll.; C. H. Highfield, Guy's; B. L. Hodge, St. Bart.'s; D. S. Jackson, St. Mary's; Morfydd R. Jones, Royal Free; A. K. A. Khalik, Cairo; O. F. A. Krause, Guy's; M. E. Lampard, King's Coll.; E. D. Lawrence, St. George's; Anne T. Leigh, Manchester; W. S. Macgowan, Middlesex; W. K. McKinstry, St. Bart.'s; Alice M. C. Macpherson, Royal Free; R. Marnham, St. George's; K. V. Mead, St. Thomas's; H. P. F. Modder, St. George's; W. S. Morgan, St. Bart.'s; Doris Nicklin, Birmingham; G. F. Oakden, St. Thomas's; A. B. Osbourne, St. Mary's; M. E. J. Packer, Bristol; J. D. L. Perera, Ceylon and London; G. L. S. Plumbly, Univ. Coll.; Nellie L. Pyman, Charing Cross; J. Raisman, Leeds; J. L. Reeve and J. B. W. Roberton, St. Bart.'s; N. L. Russell, St. George's; A. Sebba, London; H. Simmonds, St. Bart.'s; J. H. Simmons, King's Coll.; L. G. Smith, St. Bart.'s; Nettie H. Stein, St. Mary's; A. L. Stephen, Univ. Coll.; T. W. Stephens, St. Thomas's; A. C. Taylor, Guy's; G. F. Taylor, King's Coll.; Constance P. Thomas, Cardiff; F. T. Thorpe, Birmingham; Beatrice E. Turner, Royal Free; W. Twort, Univ. Coll.; Florence M. Wallen, Cardiff; Kathleen M. Ward, Liverpool; P. Weiner, King's Coll.; H. J. Williams, Birmingham; W. B. Williams, Cardiff; J. H. Willis, London; and A. T. Worthington, St. Bart.'s.

Surgery.—D. A. Abernethy, St. Bart.'s; C. P. Allen, Liverpool; C. B. Andreae, Guy's; J. R. Armstrong, St. Bart.'s; H. K. Ashworth, Manchester; E. Bacon, St. Bart.'s; C. V. N. Baldry, Sydney; D. E. Barton, St. Mary's; J. M. Bassett, Edinburgh; G. F. G. Batchelor, St. Andrews; J. R. Beal, Manchester; C. E. Beare, Middlesex; F. G. Beauchamp, Birmingham; A. D. Belilios, St. Thomas's; J. G. Y. Bell, King's Coll.; R. J. I. Bell, St. Bart.'s; J. L. Berry, Birmingham; H. McI. Birch, Adelaide and London; E. Bowen-Jones, Guy's; H. C. Boyde, St. Bart.'s; G. P. Brooks, London; A. S. S. Brown, Liverpool; J. W. D. Buttery, St. Bart.'s; F. F. R. Carreck, St. Mary's; R. T. Chadwick, St. Bart.'s; H. N. Collier, Guy's; Celia M. M. Culver-Evans, Royal Free; R. S. Davidson, Manchester; C. I. Davies, London; J. J. F. Dunn, St. Mary's; J. Y. Eccles, St. Thomas's; R. W. Edwards and A. Elliott, Guy's; E. Evans, Sheffield; M. Fine, London; S. J. Firth, Manchester; M. Fishman, St. Bart.'s; H. K. Fozdar, London; E. A. Freeman, St. Bart.'s; L. O. F. Fysh, London; J. Gore, Birmingham; Edith L. Gould, Royal Free; S. J. P. Gray, St. Bart.'s; A. W. T. Green, Middlesex; Margaret K. Green, St. Mary's; T. W. Griffiths, Middlesex; J. L. Groom, Guy's; A. Gross, St. Bart.'s; Emily M. Hall, St. Mary's; Helen M. Harris, Royal Free; L. F. A. Harrison, St. Bart.'s; J. W. Hart, Univ. Coll.; B. E. Hawkins, Guy's; J. C. Heal, Liverpool; C. H. Heaton, Birmingham; C. H. Ho, St. Thomas's; J. C. Hogg and L. Holmes, St. Bart.'s; E. Hughes, Liverpool; T. L. Jenkins, Middlesex; C. W. Jones, King's Coll.; Helen V. Jones, St. Mary's; R. Jones, Charing Cross; J. J. Keevil, St. Thomas's; J. H. Kitson, Manchester; Y. N. Lal, Dundee; I. Landon, St. Bart.'s; R. L. J. Le Clezio, St. Thomas's; H. E. Lewis, Guy's; I. McPherson, Middlesex; M. L. Maley and T. E. Malins St. Bart.'s; W. N. Maple and H. R. R. Mavor, St. Thomas's; K. N. Mawson, Liverpool; R. C. May, Guy's; R. H. Metcalfe, St. Thomas's; G. C. Milner, London; Mary A.

Monro, Royal Free ; W. J. Moody, London ; G. C. Morris, St. Mary's ; W. B. Norcott, Guy's ; Jessie G. A. Norman, Charing Cross ; J. E. J. Palser, London ; C. F. Parry, Guy's ; W. E. C. Parry, Univ. Coll. ; G. Paterson, St. Thomas's ; H. L. Peake, Guy's ; L. V. Pearson, St. Bart.'s ; H. Peaston, Liverpool ; B. Perchman, Charing Cross ; T. J. Pittard, St. Bart.'s ; W. G. Platt, Leeds ; C. G. E. Plumstead, St. George's ; F. H. Pratt, Guy's ; F. E. Roberts, Birmingham ; Victoria A. Roberts, Royal Free ; K. E. R. Robertson, St. Mary's ; K. G. Salmon, St. Bart.'s ; H. Scudamore, London ; F. L. G. Selby, St. Mary's ; F. G. A. Shaheed, Westminster ; Sara C. A. Sharpe, St. Mary's ; T. St. J. H. Silvester, J. A. Simons, and E. G. Smallbone, Guy's ; R. H. Smith, Manchester ; M. Sourasky, Leeds ; S. Speck, Middlesex ; B. L. Steele, Univ. Coll. ; Gertrude H. C. Stinson, Royal Free ; F. W. Ta'Bois, London ; C. C. Taffs, St. Thomas's ; D. E. Thomas, St. Bart.'s ; D. W. R. Thomas, Middlesex ; J. E. Thomas, Cardiff ; Dorothy I. Valentine, Liverpool ; D. C. Virmani, Charing Cross ; P. R. Viviers and W. F. Waudby-Smith, St. Bart.'s ; Elizabeth M. Whishaw, St. Mary's ; E. A. White and J. S. Whitton, St. Bart.'s ; G. O. Williams, Liverpool ; T. I. Williams, Guy's ; J. H. Willis, London ; D. B. Wilson, Birmingham ; H. F. Wilson, London ; and H. Yousri, Birmingham.

Midwifery.—J. H. Anderson, Guy's ; D. G. Balakirsky, Middlesex ; C. V. N. Baldry, Sydney ; H. I. C. Balfour, St. Bart.'s ; W. A. Ball, King's Coll. ; J. M. Bassett, Edinburgh ; J. R. Beal, Manchester ; C. E. Beare and M. Behr, Middlesex ; A. D. Belilios, St. Thomas's ; J. G. Y. Bell, King's Coll. ; W. F. D. Benton, St. Bart.'s ; S. N. Bhansali, Rotunda ; S. S. Bhatnagar, Middlesex ; G. H. Bickmore, Charing Cross ; C. A. Birch, Liverpool ; Mabel C. Booysen, Charing Cross ; H. C. Boyde, St. Bart.'s ; G. J. O. Bridgeman, Cambridge and St. George's ; Theodora Brookes, Royal Free ; A. S. S. Brown, Liverpool ; J. A. S. Brown, London ; T. E. Brown, St. Thomas's ; W. Buckley, London ; H. A. Bulman, Middlesex ; R. C. L'E. Burges, Birmingham ; T. J. Burke, Cardiff and Charing Cross ; J. W. D. Buttery, St. Bart.'s ; H. A. Byworth, St. George's ; Irene F. Callender, St. Mary's ; J. P. Carpenter, Birmingham ; A. G. Chamberlain, St. Bart.'s ; R. Childs, St. Thomas's ; Dorothy A. Chown and Alison M. Clark, St. Mary's ; J. G. Cox, St. Bart.'s ; E. A. Darukhanawalla, Middlesex ; A. E. de Fonseka, King's Coll. ; W. H. Dowell, Guy's ; Muriel E. Drew, Bristol ; F. W. Dunn, Charing Cross ; J. Dywien, Guy's ; R. W. B. Ellis and A. K. H. El Shurbagi, St. Thomas's ; H. Evans, London ; T. F. Everett, Middlesex ; J. A. Eyres, King's Coll. ; O. F. Farndon and R. R. Fells, St. Bart.'s ; M. Fine, London ; M. Fishman, St. Bart.'s ; W. S. Flowers, Leeds ; E. A. Freeman and W. F. Gaisford, St. Bart.'s ; Margaret E. J. Gashion and Edith Giles, Charing Cross ; B. M. C. Gilsenan, St. Bart.'s ; A. Glatt, Liverpool ; Dorothy Godden, Royal Free and St. Mary's ; Myrtle S. Goldrich, Charing Cross ; Edith L. Gould, Royal Free ; Phyllis M. Grainger, Birmingham ; S. J. P. Gray, St. Bart.'s ; W. H. Green, Middlesex ; C. R. M. Greenfield, St. Bart.'s ; L. A. N. Greenway, King's Coll. ; Margaret H. Greg, Manchester ; G. J. Gregerson, Adelaide and London ; J. C. P. Grey, St. Thomas's ; G. J. Gross, King's Coll. ; W. V. Harke, St. Thomas's ; Helen M. Harris, Royal Free ; L. J. Haydon, St. George's ; Dorothy G. Hervey, Birmingham ; J. D. Hindley-Smith, St. George's ; W. S. Hinton, B. L. Hodge, J. C. Hogg, and L. Holmes, St. Bart.'s ; R. St. J. Honner. Sydney and London ; Kathleen M. Horton, London ; E. Hughes, Liverpool ; C. L. Hunt, St. Bart.'s ; D. S. Jackson, St. Mary's ; P. B. Jackson, Middlesex ; W. T. Jones, Cardiff ; A. K. A. Khalik, Cairo ; I. Landon, St. Bart.'s ; F. J. L. Lang, St. Mary's ; R. L. J. Le Clezio, St. Thomas's ; D. W. E. Lloyd, Guy's ; Janet Lochore, Westminster and Royal Free ; Joan L. Lush, Univ. Coll. ; Elsie Lyon and Margaret B. MacDonald, Charing Cross ; J. R. Macdougall, St. Bart.'s ; Alice M. C. Macpherson, Royal Free ; I. McPherson, Middlesex ; M. L. Maley, St. Bart.'s ; R. Marnham, St. George's ; Mary A. Marshall, St. Mary's ; S. R. Matthews, Middlesex ; K. N. Mawson, Liverpool ; C. A. L. Meredith, Middlesex ; T. C. Mort, Cardiff ; A. H. Musgrove and D. A. Newbery, Guy's ; E. J. Newman, London ; Norah M. A. Niall, Charing Cross ; H. A. Nicholls, St. Bart.'s ; M. G. Nimatallah, Guy's ; M. Odess, St. Mary's ; C. E. Ogden, St. Bart.'s ; E. J. O'Keeffe, London ; Gwynedd M. E. Olive, Royal Free ; A. Orliansky, Middlesex ; Catherine E. Orr-Ewing, Royal Free ; M. N. Oster, Westminster ; M. E. J. Packer, Bristol ; J. G. Paley, St. Bart.'s ; Florence M. Parsons, Charing Cross ; L. V. Pearson, St. Bart.'s ; G. E. G. Peirce, St. Mary's ; K. R. T. Peiris, King's Coll. ; L. C. Peringuey, Manchester ; G. L. S. Plumbly, Univ. Coll. ; N. R. Pooler, St. Mary's ; F. H. Pratt, Guy's ; D. C. Price, St. Bart.'s ; Agnes M. Ramsbotham, Royal Free ; Margaret G. P. Reed, King's Coll. ; R. I. Richards, St. George's ; Margaret A. Ritchie, Charing Cross ; Janet M. Robertson, St. Mary's ; Alice L. Robson, Royal Free ; G. E. Rowan, St. Thomas's ; I. Sachs, Middlesex ; H. Scudamore, London ; S. T. Seccombe, St. Thomas's ; H. N. Seymour-Isaacs, St. Bart.'s ; H. Shenouda, Cardiff ; H. J. A. Simmons, Middlesex ; Nancie A. Simmons, Charing Cross ; J. A. Simons, Guy's ; R. K. Smith, St. Bart.'s ; S. Speck, Middlesex ; J. Spencer, St. Bart.'s ; C. A. Stanley, St. Thomas's ; Nettie H. Stein, St. Mary's ; T. W. Stephens, St. Thomas's ; A. F. H. Stewart, Guy's ; R. G. Strouts, London ; H. Syed, King's Coll. ; F. W. Ta'Bois, London ; L. D. J. Telesphor, Univ. Coll. ; G. P. Thorold, St. Thomas's ; F. T. Thorpe, Birmingham ; O. R. Tisdall, St. Bart.'s ; Mary M. Tulloch, Charing Cross ; Beatrice E. Turner, Royal Free ; I. Vitenson, London ; P. R. Viviers, St. Bart.'s ; E. Walsh, Manchester ; L. H. F. Walton, St. Thomas's ; Elizabeth M. Whishaw, St. Mary's ; C. H. C. White, Guy's ; E. A. White and J. S. Whitton, St. Bart.'s ; Addie Wilkes, Charing Cross ; E. G. Williams, Leeds ; Jane C. Williams, St. Mary's ; J. I. Williams, Middlesex ; A. G. Wilson, St. Thomas's ; H. F. Wilson, London ; Eileen C. Wise, King's Coll. ; H. P. Yew, Guy's ; H. Yousri, Birmingham ; and A. M. M. Zeiwer, St. George's.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—An extraordinary Comitia of the College was held on May 14th, Sir Humphry Rolleston, the President, occupying the chair. It was announced that Dr. Bernard Hart would deliver the Goulstonian lectures, Dr. A. Shadwell the FitzPatrick lectures, and Sir Thomas Horder the Lumleian lectures for 1926.—Those gentlemen who were elected to the Fellowship on April 30th were admitted as Fellows.—A supplementary list of 96 candidates to whom licences to practise physic had been granted was submitted as follows. (The medical schools at which the candidates studied will be found in the list of the Royal College of Surgeons.)

*Agnes L. Adam, David Aserman, Edmund L. Auguste, Charles W. Bamford, Philip S. Bell, Riad H. Bestawros, Arthur T. Bettinson, *Margaret Bowstead, Paul D. Braddon, *Gwenddolen J. Brooke, *Stella M. Brown, *Dora M. Cadman, *Mary E. Campbell, Walter E. Chiesman, *Eileen M. Clarke, *Gladys M. Clarke, *Winifred M. Clement, Douglas R. T. Clendon, Isaac Cohen, Ronald W. Cuningham, Stefanus H. Daneel, Gwylon Davies, Howell J. Davies, Douglas S. Dixon, John V. Dockray, Dennis C. Drake, William Egan, Valentine H. Ellis, Anthony J. K. Finch, *Barbara Finch, *Winifrede M. Fish, Victor L. Fisher, Mark Footerman, Ganesh V. Gollerkeri, Arkyl S. Gough, Ralph Green, Charles J. Grosch, Ronald F. Guymer, Leslie B. Haye, John B. Hayes, *Barbara J. Hick, *Nancy M. Hield, Alfred R. Hill, Alan T. Howell, John U. Human, *Dorothea A. C. Hunt, Jack N. Jacobson, Herman Kessel, Arthur M. Lazarus, Samuel Lerner, Solomon Levy, Cyril J. Lovering, Derek A. Lubbock, James W. McGuire, Alexander C. MacLeod, Douglas H. MacLeod, Duncan R. Martin, Alistair Mead, George C. Michael, *Ruth L. Milne, Edward F. Molony, John P. Monkhouse, Herbert Moore, Arthur H. Morley, Victor M. * Under the Medical Act, 1876.

The application of Dr. Hugh Roger Smith for restoration of the Membership, relinquished in 1919, was granted.—Dr. Raymond Crawfurd was appointed a member of the Committee of Management to fill the vacancy caused by the death of Dr. J. A. Ormerod.—The President announced that he had nominated Sir P. Horton-Smith Hartley as representative of the College at the Conference of the National Association for Prevention of Tuberculosis.—It was decided to appoint a subcommittee to consider and codify the by-laws in view of recent alterations in them.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At an ordinary meeting of the Council of the College on May 14th, Sir John Bland-Sutton, President, in the chair, the Secretary reported the death of Sir Rickman Godlee, Bart., K.C.V.O., past President and past member of the Council and of the Court of Examiners, whereupon the following vote of condolence was unanimously passed :—

> That the Council hereby express their deep regret at the death of Sir Rickman Godlee and their very sincere sympathy with Lady Godlee in the great loss which she has sustained. The Council also desire to express their grateful sense of the many services rendered to the College by Sir Rickman Godlee as an examiner and member of the Council, and especially to record their appreciative recognition of the distinction and ability with which he fulfilled the duties of President during his three years of office. The Council feel that the surgical profession has lost one of its ablest leaders whose skill in practice and many accomplishments will cause his name always to be held in honoured remembrance.

A letter was read from Mr. G. Percy Dodds-Parker resigning his appointment as a member of the Court of Examiners in Surgery. The resignation was accepted and the vacancy will be filled at the Quarterly Council in June.—Prof. Antonin Gosset, of Paris, was introduced, and having signed the roll of Honorary Fellows was presented with the Diploma of Honorary Fellowship.

Diplomas of Member were conferred upon 234 candidates (including 42 women) who have passed the requisite examinations and have complied with the by-laws. The following are the names and medical schools of the successful candidates :—

Agnes L. Adam, Royal Free ; C. S. Anderson, St. Mary's ; D. Aserman, Cambridge and St. Thomas's ; E. L. Auguste, Middlesex ; C. W. Bamford, Calcutta and London ; W. A. Barnes, Cambridge and St. Bart.'s ; St. C. E. J. Barrett, Belfast and Middlesex ; J. R. Beagley, St. Bart.'s ; I. C. P. Beauchamp, Cambridge and Guy's ; Diana J. K. Beck, Royal Free ; P. R. T. Becker, Cape and Guy's ; P. S. Bell, Westminster ; Elizabeth E. Benson, Bristol ; R. H. Bestawros, Cairo and London ; A. T. Bettinson, St. Bart.'s ; C. P. Blacker, Guy's ; W. R. W. Bonner-Morgan, Cardiff and St. Bart.'s ; E. H. Boodrie, Calcutta and St. Mary's ; Margaret Bowstead, Royal Free ; D. de C. Boxill, Long Island and St. Mary's ; P. D. Braddon, Sydney ; P. G. Brain, London ; M. K. Braybrooke, St. George's ; R. B. Brew, Univ. Coll. ; C. W. Brook, Cambridge and St. Bart.'s ; Gwenddolen J. Brooke, Univ. Coll. ; G. M. Brooks, Birmingham ; Stella M. Brown, King's Coll. ; M. F. Butler, Guy's ; Dora M. Cadman, Royal Free ; Mary E. Campbell, Charing Cross ; L. I. M. Castleden, St. Bart.'s ; Enid A. Ceiriog-Cadle, Royal Free ; M. Chandra, Punjab and St. George's ; R. J. K. Chattey, Middlesex ; W. E. Chiesman, Cambridge and St. Thomas's ; J. E. Church, Cambridge and St. Bart.'s ; Eileen M. Clarke, Royal Free ; Gladys M. Clarke, Royal Free and St. Mary's ; Winifred M. Clement, Royal Free and Charing Cross ; D. R. T. Clendon, Univ. Coll. ; Hilda A. Cohen, Cardiff ; I. Cohen, Middlesex ; Jean Cooper, Punjab and Royal Free ; Catherine A. Cowan, Royal Free ; P. V. Crameri, Univ. Coll. ; D. P. Crawford, St. Thomas's ; D. A. L. Crawshaw, Guy's ; Victoria M. Crosse, Royal Free ; G. P. Crowden, Univ. Coll. ; J. Crowther and J. Cumming, Manchester ; R. W. Cuningham, Guy's ; R. N. Curnow, St. Bart.'s ; R. R. Dalling, Liverpool ; S. H. Daneel, Cape and Guy's ; H. E. Daniel, Cardiff and St. Bart.'s ; G. Davies, Guy's ; H. J. Davies, St. Mary's ; R. K. Debenham, Cambridge and London ; A. E. de Chazal, Univ. Coll. ; J. D. Dillon, Liverpool and St. Bart.'s ; D. S. Dixon, Middlesex ; J. V. Dockray, Cambridge and Middlesex ; W. H. A. Dodd, Liverpool ; A. S. M. Douglas, Guy's and St. George's ; J. L. C. Doyle, St. Bart.'s ; D. C. Drake, Guy's ; W. Egan, Charing Cross ; V. H. Ellis, Cambridge and St. George's ; G. I. Evans, Manchester ; P. F. Evans, London ; Christabel S. Eyre, Charing Cross ; C. R. Fielding, Manchester ; A. J. K. Finch, St. Mary's ; Barbara Finch, Royal Free ; Winifrede M. Fish, King's Coll. ; V. L. Fisher, Guy's ; F. J. T. Foenander, Middlesex ; M. Footerman, Univ. Coll. ; C. A. Francis, Cambridge and St. Bart.'s ; D. B. Fraser, St. Bart.'s ; H. E. Gamlen, St. Thomas's and Durham ; A. W. Gardner, St. Bart.'s ; J. H. Gibbens, Cambridge and St. Thomas's ; G. D. Gillbard, Middlesex ; A. Gompertz, Durham ; R. T. Goodyear, Cambridge and Liverpool ; G. V. Gollerkeri, Bombay and Middlesex ; A. S. Gough, Guy's ; D. R. Grant, Alberta and Guy's ; R. Green, St. Bart.'s ; C. J. Grosch, Cambridge and Middlesex ; R. F. Guymer, Cambridge and St. Thomas's ; G. S. Hale, St. Bart.'s ; S. Harris, Oxford and St. Thomas's ; J. H. Hartland, Birmingham ; F. C. Haward, St. Thomas's ; L. B. Haye, Univ. Coll. ; J. B. Hayes, Charing Cross ; Marjorie F. M. Hayward, London ; H. L. Heath, Birmingham ; Catherine M. Hext, London ; Barbara J. Hick, Royal Free and St. Mary's ; Nancy M. Hield, Royal Free ; A. R. Hill and H. F. Hiscocks, St. Bart.'s ; F. D. M. Hocking, Middlesex ; R. G. Hodder, St. Thomas's ; A. T. Howell, Cambridge and St. Thomas's ; H. B. Howell, St. Bart.'s ; J. E. Howie, Liverpool ; W. Hughes, Middlesex ; J. U. Human, Guy's ; Dorothea A. C. Hunt, Royal Free ; J. T. Hunter, St. Bart.'s ; J. N. Jacobson, Cape and St. Thomas's ; I. S. Jacobsz, Cape and Guy's ; M. E. M. Jago, Guy's ; L. E. Jones, Cardiff and St. Thomas's ; L. R. Jones, Guy's ; W. H. M. Jones, Cardiff ; B. Kaplansky, Cape and London ; P. N. Kapur, Lahore and London ; R. St. J. Kemm, Bristol ; H. Kessel, Guy's ; G. M. King, Cardiff and King's Coll. ; J. G. Kingsbury, Guy's ; C. K. Lakshmanan, Madras and St. Bart.'s ; J. C. C. Langford, St. Bart.'s ; Kathleen M. Lankester, Royal Free ; A. M. Lazarus, Melbourne ; G. A. Q. Lennane, Cambridge and St. Thomas's ; S. Lerner, Univ. Coll. ; H. M. O. Lester, St. Thomas's ; Muriel A. Lester, Royal Free ; S. Levy, Middlesex ; T. J. Lloyd, Cardiff ; C. J. Lovering, Cardiff and Middlesex ; D. A. Lubbock, Univ. Coll. ; J. W. McGuire, Calcutta and St. Mary's ; A. C. MacLeod and D. H. MacLeod, Middlesex ; A. McMillan, Birmingham ; D. R. Martin, Guy's ; S. P. Meacock, Cardiff and Guy's ; A. Mead, St. Thomas's ; G. C. Michael, London ; Ruth L. Milne, Royal Free ; J. G. Milner, Cambridge and St. Bart.'s ; V. S. Mitcheson, Cambridge and Birmingham ; E. F. Molony, Cambridge and St. Bart.'s ; J. P. Monkhouse, St. Mary's ; S. K. Montgomery, Univ. Coll. ; A. J. Moody and C. A. Moody, St. Bart.'s ; Florence I. R. Moore, Royal Free ; H. Moore, Belfast and Guy's ; A. H. Morley, Leeds ; V. M. Morris, Middlesex ; W. G. R. Morris, Bristol ; I. S. Moscow, St. Bart.'s ; C. A. Mulligan, Manchester ; G. W. Murray, Guy's ; Marjorie Murrell, Royal Free ; W. Ogden, St. Bart.'s ; J. B. Oldham, Liverpool ; Dorothy M. Payton, Birmingham ; A. P. Pearce, Leeds and London ; C. O. Perera, Ceylon ; A. Pierce, Birmingham ; E. P. Pratt, Durham and St. George's ; B. Press, St. Bart.'s ; G. H. Pringle, Univ. Coll. ; P. E. Pym, Cambridge and St. Bart.'s ; Fanny Rabinowitz, Charing Cross ; J. Rafalowsky, Zurich and Univ. Coll. ; S. Randall, London ; D. I. Rees, St. Thomas's ; T. Rees, Manchester and St. Bart.'s ; Nellie H. Reynolds, King's Coll. ; Grace D. Rice, St. Mary's ; H. S. Rich, Sydney and Middlesex ; A. W. Riddolls, Guy's ; G. D. Robb, Otago and Middlesex ; C. E. Roberts, Oxford and London ; A. E. Ross, St. Bart.'s ; Edith M. Ross-Johnson, Univ. Coll. ; J. E. C. Rouse, St. George's ; A. T. F. Rowley, Bristol ; T. W. E. Royden, Cambridge and St. Bart.'s ; Martha N. Russell, Cape and Royal Free ; H. H. E. Schulz, Cape and St. Thomas's ; T. A. Seekings, Univ. Coll. ; H. J. Selby, Guy's ; R. Sellick, St. Thomas's ; D. G. Shields, Cambridge and St. Bart.'s ; C. F. J. Smith, St. Mary's ; J. R. Smith, Cambridge and St. Bart.'s ; Beatrice M. Smithies, Charing Cross ; K. A. Soutar, St. Thomas's ; J. S. Spickett, Cardiff and St. Bart.'s ; A. A. Spiro, Manchester ; E. F. Stead, London ; G. H. Steele, Univ. Coll. ; J. M. Stirling, Madras and Charing Cross ; S. V. Strong, Guy's ; Sylvia Sworn, Univ. Coll. ; J. E. Swyer, London ; J. S. Symons, London ; H. K. Tan, Hong-Kong and Middlesex ; Catharine F. Taylor, Royal Free ; G. Taylor, St. Mary's ; J. G. S. Thomas, Oxford and Guy's ; P. G. Trafford, Guy's ; Henrietta Trend, Royal Free ; Joan W. Urwick, Charing Cross ; K. H. Uttley, Cambridge and Univ. Coll. ; N. A. A. van Buuren, Cape and Univ. Coll. ; J. M. van Schalkwyk, Cape and Guy's ; T. E. Walsh, Cambridge and St. Thomas's ; Y. S. Wan, Cambridge and St. Bart.'s ; E. C. Warner and R. L. Waterfield, Guy's ; Helen D. Watson, Royal Free ; M. Weisman, Paris and Manchester ; W. S. Whimster, Guy's ; R. A. K. Wiener, Cape and St. Thomas's ; R. M. Windeyer, Cambridge and St. Bart.'s ; H. G. Wimbush, Cambridge and Guy's ; K. K. Wood, Manchester ; J. Wood, King's Coll. ; H. M. Woodman, Cambridge and King's Coll. ; and H. C. Wykerd, Cape and London.

UNIVERSITY OF LONDON : REPORT OF THE PRINCIPAL OFFICER.—Sir Cooper Perry, in his report on the work of the University during the year 1924-25, records a slight decrease in the total number of admissions and of matriculations compared with the previous year. The chief item of medical interest during the year was the granting of a Charter to the London School of Hygiene and Tropical Medicine in consequence of which the Department of Bacteriology and Public Health of King's College will be closed at the end of the present session. Prof. H. R. Kenwood having resigned the Chadwick Chair of Hygiene at University College, no steps are being taken at present to fill that chair. The Principal Officer adverted to the foundation of new chairs in the hospital medical schools announced during the year : a Chair of Physics at St. Bartholomew's Hospital Medical College to which Dr. F. L. Hopwood has been appointed ; a Chair of Medicine at the London Hospital Medical College, Dr. A. W. M. Ellis occupying it ; the S. A. Courtauld Chair of Anatomy at the Middlesex Hospital Medical School with Dr. T. Yeates as the first holder ; the Chair of Biochemistry at the same school ; a new Chair of Pathology at the London School of Medicine for Women with Dr. J. H. Dible as the first holder ; the granting of the title of Professor of Anatomy to Mrs. M. F. Lucas Keene at the same school, and the title of Professor of Surgery to Mr. C. C. Choyce at University College Hospital Medical School. During the year progress has been made in the visitatorial inspection of the various schools of the University. The Principal Officer notes that correspondence has passed during the year between the University and the Treasury upon the subject of the Bloomsbury site, decision on which is still deferred. Whatever may be the result of the deliberations of the departmental committee, Sir Cooper Perry writes : "We may await with confidence its findings, not unmindful that in whatever form the body of our constitution be moulded, the spirit which gives life and growth remains always within ourselves alone."

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—Beginning on June 2nd, a four weeks' course in the study of Venereal Disease will be held at the London Lock Hospital (Dean-street). The out-patient departments will be open to post-graduates enrolling for the course and in the afternoons will be given a lecture by one of the members of the staff dealing with the diagnosis and methods employed for combating this disease. As the course is only held if eight entries are received, early application is desirable. There will also be a four weeks' course in Dermatology at the St. John's Hospital from June 2nd to 27th. From June 3rd to 25th eight clinical demonstrations will be given at the London School of Hygiene and Tropical Medicine. The subjects considered will be the more important diseases of tropical countries illustrated by cases in the hospital. There will also be a course in Gynæcology at the Chelsea Hospital for Women from June 8th to 27th, when opportunities will be afforded for attending operations, demonstrations in the out-patient department, and ward rounds. From June 8th to 20th, at the Victoria Park Hospital for Diseases of the Heart and Lungs, there will be given a special course consisting of lectures and demonstrations on Sunlight Treatment, Artificial Pneumothorax, the Electrocardiograph, &c. From June 15th to July 11th is a four weeks' course in Urology at the St. Peter's Hospital for Stone. A fortnight's intensive course in Medicine, Surgery, and the Specialties will take place at the London Temperance Hospital from June 22nd to July 4th. Copies of the syllabus of each of the foregoing courses and the programme of the Fellowship of Medicine may be obtained from the Secretary, at 1, Wimpole-street, London, W. 1.

VISIT OF AMERICAN DOCTORS TO DUBLIN. The arrangements for the visit to Dublin of the party of American doctors which is soon to tour Europe are nearly complete. So many of the visitors wish to include Ireland in their tour that it has been found necessary to divide the party into two, as the hotel accommodation in Dublin would be insufficient. According to present arrangements, the first party will reach Dublin on the morning of June 11th. On that morning the guests will attend at any of the city hospitals where the various surgeons will operate or exhibit cases, and the physicians will conduct parties through the wards. In the afternoon Prof. F. C. Purser will open a discussion on encephalitis lethargica, in which some of the Americans will take part. Next morning there will be a discussion on exophthalmic goitre, to be opened by Prof. T. G. Moorhead; Mr. C. H. Mayo has promised to take part in this discussion. In the afternoon the Governor-General is giving a garden party, and the visitors then depart for Belfast. The second party is to arrive on the morning of Saturday, the 13th, and will leave for Belfast on Monday afternoon, the 15th. On the Saturday morning Dr. G. FitzGibbon and Prof. J. W. Bigger will open a discussion on puerperal sepsis. At all the sessions there will be exhibitions of rare and interesting cases.

Lebanon Hospital for Mental Diseases, Syria. The annual meeting will be held at the rooms of the Medical Society of London, 11, Chandos-street, Cavendish-square, W., on Wednesday, May 27th, at 3.30 p.m. Dr. E. W. G. Masterman will be in the chair, and the speakers will include Sir Wyndham Deedes and Pastor Hoffmann de Visme (representing Switzerland).

Failure to Notify Small-pox.—For failing to notify that two of his children were suffering from small-pox a man, who was stated to be a confectioner, at Dukinfield, Lancs, on May 14th, was fined £5 and a daughter who assisted him was fined £1, the total amount of costs being £10 15*s.* It was stated in court that although the children had small-pox the defendants continued to bake and sell foodstuffs.

The late Mr. W. Percy Blumer, F.R.C.S.—The death occurred in London, on May 12th, of William Percy Blumer, F.R.C.S. Edin., at the age of 70. Mr. Blumer had an extensive practice in Sunderland before coming to London in 1914. He received his medical education in Edinburgh, at the University and the Royal Colleges, and qualified L.R.C.P. & S. in 1876, obtaining the F.R.C.S.E. in 1884. He settled in Sunderland, and for over 20 years was an honorary surgeon of the Sunderland Royal Infirmary. He also held the posts of honorary surgeon to the Monkwearmouth Hospital and to the Durham County and Sunderland Eye Infirmary. His contributions to medical literature include several papers on abdominal surgery in the medical journals, and in 1911 he described a case of albinism which was published in Pearson, Nettleship, and Usher's Monograph on Albinism in Man. Mr. Blumer leaves a widow and two daughters, his son having been killed in the war.

Medical Diary.

SOCIETIES.

ROYAL SOCIETY, Burlington House, W.
Thursday, May 28th.—4.30 p.m.—*Papers to be read:* R. J. Ludford: Cell Organs during Secretion in the Epididymis. (Communicated by Prof. A. V. Hill.) R. J. Ludford: Nuclear Activity in Tissue Cultures. (Communicated by Prof. A. V. Hill.) J. Needham and Dorothy Needham: The Hydrogen-Ion Concentration and the Oxidation Reduction Potential of the Cell Interior. A Micro-Injection Study. (Communicated by Sir Frederick Hopkins.) F. W. R. Brambell: The Oogenesis of the Fowl (Gallus Bankiva). (Communicated by Prof. J. P. Hill.)

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MEETINGS OF SECTIONS.

Monday, May 25th.

ODONTOLOGY: at 5.30 p.m.
At the Royal College of Surgeons, Lincoln's Inn-fields, W.C.
Annual General Meeting:
Election of Officers and Council.
Casual Communication:
Mr. E. W. Fish: Circulation of Lymph in the Dentine (preliminary report).
Exhibition:
Sir Frank Colyer: Specimens recently added to the Odontological Museum.

Tuesday, May 26th.

MEDICINE: at 5.30 p.m.
Annual General Meeting:
Election of Officers and Council.

Wednesday, May 27th.

COMPARATIVE MEDICINE: at 5 p.m.
Annual General Meeting:
Election of Officers and Council.
Paper:
Dr. J. H. Sequeira: Parasitic Affections of the Skin communicated from Animals to Man.

Thursday, May 28th.

EPIDEMIOLOGY AND STATE MEDICINE: at 5.30 p.m.
Annual General Meeting:
Election of Officers and Council.
Death of Dr. Dudfield: Resolution to be moved by Senior Honorary Secretary.
Paper:
Dr. John Brownlee: The Health of London in the Eighteenth Century.

UROLOGY: at 8.30 p.m.
Annual General Meeting:
Election of Officers and Council.
Paper:
Mr. Winsbury White: Hydronephrosis.
(Mr. White will show his Hunterian specimens.)

MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES, 11, Chandos-street, Cavendish-square, W.
Friday, May 29th.—8.30 p.m., Papers by Sir Henry Simson and Mr. Aleck Bourne on the Diagnosis and Treatment of Venereal Diseases in Pregnancy. A Discussion will follow.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.
Monday, May 25th, to Saturday, May 30th.—West Lecture Hall, Royal Society of Medicine. Lecture arranged by the Fellowship of Medicine, and open to all members of the medical profession. At 5.30 p.m., Mr. G. Gordon-Taylor: The Prevention and Treatment of Shock in the Surgery of the Abdomen.—London Temperance Hospital, Hampstead-road, N.W. Special Post-graduate Course for Practitioners. Daily at 4.30 p.m., Clinical demonstration for one hour, followed by a lecture for half an hour. General medicine, surgery, and special departments (second week).—Infants Hospital, Vincent-square, S.W. Special Course in Diseases of Infants. Lectures and demonstrations every afternoon. "Round-table" Conference on Friday, and special visits on Saturday afternoon and Sunday morning.—Hospital for Diseases of the Skin, Blackfriars, S.E. Post-graduate Course in Dermatology, consisting of instruction in the Out-patient Department every afternoon, and a Venereal Clinic on Tuesday and Friday (second week).—Central London Throat, Nose, and Ear Hospital, Gray's Inn-road, W.C. Special Course in Laryngology, Rhinology, and Otology. Daily operations, lectures, and clinics. Morning and afternoon sessions. Operative surgery class every morning. Clinical and Operative Courses may be taken separately (second week).—Maudsley Hospital, Denmark-hill, S.E. Course in Psychological Medicine. Lectures on the Psychoneuroses, on the Practical Aspect of Mental Deficiency, on the Pathology of Mental Diseases; Demonstrations in Clinical Psychiatry and Clinical Neurology (second week).

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.
Monday, May 25th.—12 noon, Mr. Simmonds: Applied Anatomy. 2 p.m., Mr. Addison: Surgical Wards. 2 p.m., Dr. Scott Pinchin: Medical Out-patients.
Tuesday.—11 a.m., Mr. Endean: Venereal Diseases. 12 noon, Dr. Burrell: Chest Cases. 2.30 p.m., Mr. Tyrrell Gray: Surgical Wards.
Wednesday.—11 a.m., Medical Registrar: Medical Wards. 2 p.m., Dr. Owen: Medical Out-patients. 2 p.m., Dr. Dowling: Skin Dept.
Thursday.—11 a.m., Sir Henry Simson: Gynæcological Wards. 12 noon, Dr. Pritchard: Modern Methods in Medicine. 4 p.m., Dr. Dowling: Seborrhœa and Seborrhœic Dermatitis.
Friday.—11 a.m., Dr. McDougal: Electrical Dept. 12 noon, Surgical Registrar: Surgical Pathology. 2 p.m., Mr. Vlasto: Throat, Nose, and Ear Dept.
Saturday.—10 a.m., Dr. Saunders: Medical Diseases of Children. 10 a.m., Mr. Banks-Davis: Operations on Throat, Nose, and Ear.
Daily, 10 a.m. to 6 p.m., Saturdays, 10 a.m. to 1 p.m., In-patients, Out-patients, Operations, Special Departments.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.
Tuesday, May 26th.—4.30 p.m., Mr. E. S. Pierrepont: Various Methods of Tooth Extraction.
Friday.—4.30 p.m., Dr. J. B. Alexander: Colitis.
Daily.—Clinics in General and Special Departments, Demonstrations, Operations, &c.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, Leicester-square, W.C.
Tuesday, May 26th.—5 p.m., Dr. Gray: Sclerema Neonatorum.
Thursday.—5 p.m., Dr. Adamson: Lichen Planus.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.
Thursday, May 28th.—4 p.m., Dr. A. M. H. Gray: The Eczemas of Children.

ST. MARY'S HOSPITAL INSTITUTE OF PATHOLOGY.
Thursday, May 28th.—5 p.m., Dr. W. E. Gye: The Filterable Viruses.

CHADWICK PUBLIC LECTURES.
Monday, May 25th.—5.15 p.m. (at the Royal Society of Medicine), Dr. Emile Brumpt: How to Conduct an Antimalarial Campaign.
Friday.—5.15 p.m. (at the Royal Society of Arts), Dr. Emile Brumpt: The Prophylaxis of Sleeping Sickness.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C. 1.

POST-GRADUATE COURSE: May–June, 1925.

Clinical Lectures and Demonstrations.

Monday, May 25th.—2 p.m., Out-patient Clinic: Dr. Hinds Howell. 3.30 p.m., Optic Neuritis and Papillœdema: Mr. Williamson Noble.

Tuesday, May 26th.—2 p.m., Out-patient Clinic: Dr. Walshe. 3.30 p.m., Fractures of the Skull: Mr. Donald Armour.

Thursday, May 28th.—2 p.m., Out-patient Clinic: Dr. Kinnier Wilson. 3.30 p.m., Disorders of Gait: Dr. Risien Russell.

Friday, May 29th.—2 p.m., Out-patient Clinic: Dr. Gordon Holmes. 3.30 p.m., The Cerebro-spinal Fluid in Meningitis: Dr. Greenfield.

Course of Lectures and Demonstrations on the Pathology of the Nervous System.

Monday, June 8th.—12 noon, The Neuron: Dr. J. G. Greenfield.

Course of Lectures and Demonstrations on the Anatomy and Physiology of the Nervous System.

Tuesday, May 26th.—12 noon, The Physiology of the Motor Systems: Dr. Walshe.

Thursday, May 28th.—12 noon, The Sensory System: Dr. Walshe.

Dr. H. J. Macbride will give a Course of Eight Clinical Demonstrations, chiefly on Methods of Examination of the Nervous System, in the Wards at 10 a.m. on Tuesdays and Fridays, if sufficient entries are received. The fee for this Course will be £2 2*s.* (commencing Tuesday, May 19th).

Mr. Armour and Mr. Sargent operate at the Hospital on Tuesday and Friday mornings at 9 a.m., or at such other times as may be announced.

Any part of the Course may be taken separately. Special arrangements will be made for those unable to take the whole Course.

Fees should be paid to the Secretary of the Hospital at the office on entering for the Course.

J. G. Greenfield, Dean of Medical School.

UNIVERSITY OF LIVERPOOL POST-GRADUATE LECTURES. (At 3.30 p.m.)

Tuesday, May 26th.—(At the Southern Hospital.) Dr. N. Chamberlain: Aneurysm of the Aorta.

Wednesday.—(At the Northern Hospital.) Dr. Murray Bligh: Pleural Effusion.

Thursday.—(At the Stanley Hospital.) Mr. Heaney: Surgical Cases.

Friday.—(At the Royal Infirmary.) Dr. D. Bigland: Medical Cases.

MANCHESTER ROYAL INFIRMARY.

Tuesday, May 26th.—4.15 p.m., Dr. A. H. Holmes: Aneurysm of the Aorta.

Appointments.

Cloake, Philip, M.D., B.S. Lond., M.R.C.P. Lond., has been appointed Physician for Out-patients at the Queen's Hospital, Birmingham.

Horsburgh, P. G., M.R.C.S., L.R.C.P. Lond., D.P.H., Medical Officer of Health, Nuneaton.

Yow, C. W., M.B., Ch.B. Edin., Ophthalmic Pathologist to the Royal Eye Hospital, Southwark.

University of Manchester: Duguid, J. B., M.B., Ch.B. Aberd., Lecturer in Morbid Anatomy and Histology; Susman, W., M.D. Ontario, Assistant Lecturer in Bacteriology; MacGill, Elsie I., M.Sc., Research Assistant in Entomology.

Certifying Surgeons under the Factory and Workshop Acts: Colvin-Smith, R. C. M., M.B., B.Ch. Camb. (Cromer), Orr-Ewing, A., M.B., B.Ch. Camb. (Silverton, Devon), Robertson, W. G., M.B., Ch.B. Edin. (Lanchester, Durham), Casper, W. M., M.R.C.S. Eng., L.R.C.P. Lond. (Overton, Flint).

Vacancies.

For further information refer to the advertisement columns.

Ayr, Hospital for Mental Diseases.—Jun. H.P. £300.

Beit Memorial Fellowships for Medical Research.—Jun. Fellowships. £350.

Birmingham, Public Health Dept.—Asst. Tuberc. and Sanatorium O. at rate of £500.

Blackburn County Borough.—Asst. M.O.H. and Asst. Sch. M.O. £600.

Cambridge, Addenbrooke's Hospital.—H.P. at rate of £130.

Cambridgeshire Tuberculosis Colony, Papworth Hall.—H.P. £100.

Cancer Hospital, Fulham-road, S.W.—H.S. at rate of £100.

Central London Throat, Nose, and Ear Hospital, Gray's Inn-road, W.C.—Out-patient Registrar.

Charing Cross Hospital, W.C.—Res. Anæsthetist at rate of £160.

Chelsea Hospital for Women, Arthur-street, S.W.—Sen. and Jun. H.S.'s at rate of £120 and £100 per annum respectively.

East Lancashire Tuberculosis Colony and Sanatorium, Barrowmore Hall, Great Barrow, near Chester.—Asst. M.O. £250.

Epsom, The Manor.—Jun. Asst. M.O. £140.

Essex Administrative County.—Sen. Clin. Tuberc. O. £750. Also Asst. Tuberc. O. £600.

Evelina Hospital for Children, Southwark, S.E.—H.P. £120.

Hackney Union Infirmary.—Jun. Asst. M.O. at rate of £350.

Harrogate Infirmary.—H.S. at rate of £150.

Hoo Rural District.—Part-time M.O.H. £60.

King's College Hospital, Denmark Hill, S.E.—Hon. Radiologist.

Kirkcaldy Hospital.—Res. M.O. at rate of £125.

Lambeth Parish Hospital.—Jun. Asst. M.O. £200.

Liverpool Hospital for Consumption, Mount Pleasant.—Vacancy on Hon. Med. Staff.

London Jewish Hospital, Stepney Green, E.—Asst. Surg. to Ear, Nose, and Throat Dept. Also Asst. Surg. in Gynæcological Dept.

Manchester Northern Hospital for Women and Children.—Sen. and Jun. H.S. £130 and £100 respectively.

Miller General Hospital, Greenwich-road, S.E.—Res. Cas. O. £150.

Monmouthshire County Council.—Asst. M.O. £500.

Oxford, Radcliffe Infirmary and County Hospital.—H.S. and Cas. H.S. Each at rate of £120.

Patna, India, Medical College.—Prof. of Pharmacology, Prof. of Anatomy, and Prof. of Physiology. Each Rs.1200 per mensem.

Queen Charlotte's Maternity Hospital, Marylebone-road, N.W.—Asst. Res. M.O. at rate of £80.

Rochester, St. Bartholomew's Hospital.—Res. H.S. at rate of £250.

Royal Free Hospital, Gray's Inn-road, W.C.—Asst. Cas. O., H.P. Also two H.S.'s.

Royal Northern Hospital, Holloway, N.—Two Asst. Surg. O.'s. Each £75.

Royal Waterloo Hospital for Children and Women, Waterloo-road, S.E.—Cas. O. £150. H.S. and H.P. Each at rate of £100. Also Hon. P. and Asst. in X Ray Dept.

St. Helen's Hospital, Lancashire.—Res. M.O. £250.

St. Marylebone Hospital, Ladbroke-grove, W.—Third Asst. M.O. £300.

St. Paul's Hospital for Skin and Genito-Urinary Diseases, Endell-street, W.C.—Res. M.O. Locum. £10 10*s.* weekly.

Scarborough Hospital and Dispensary.—H.S. £126.

Sheffield Royal Hospital.—Res. Surg. O. £200.

South London Hospital for Women, South Side, Clapham Common, S.W.—Asst. P.

Victoria Hospital for Children, Tite-street, Chelsea, S.W.—Hon. P. to Out-patients.

West London Hospital, Hammersmith-road, W.—H.P., H.S., Aural H.S., and Res. Cas. O. Each at rate of £100.

Windsor, King Edward VII. Hospital.—R.M.O. £200. Also Jun. H.S. at rate of £100.

The Chief Inspector of Factories, Home Office, London, S.W., announces a vacant appointment at St. Just, Cornwall.

Births, Marriages, and Deaths.

BIRTHS.

Broster.—On May 13th, the wife of L. R. Broster, M.Ch., F.R.C.S., of Wimpole-street, W., of a daughter.

DEATHS.

Baly.—On May 16th, at the Medical Superintendent's House, Lambeth Hospital, Charles Baly, retired dental surgeon, late of Harley-street, aged 79.

Blumer.—On May 12th, at a nursing home in London, William Percy Blumer, F.R.C.S. Edin., late of Muswell Hill and Sunderland, aged 70 years.

Christopherson.—On May 11th, Cecil Christopherson, surgeon, of St. Leonards-on-Sea.

Gillingham.—On May 15th, at High-road, Chiswick, Alfred Gillingham, M.R.C.S., L.R.C.P., aged 77.

Tooth.—On May 13th, at The Moat, Hadleigh, Suffolk, Howard Henry Tooth, C.B., C.M.G., M.D., F.R.C.P., late of Harley-street, aged 69.

Wilson.—On May 8th, at York, J. P. A. Wilson, F.R.C.S. Edin., late Principal Medical Officer, Johore, aged 66.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

The King has approved of the reappointment of Sir David James Galloway, M.D. Edin., to be an Unofficial Member of the Executive Council of the Straits Settlements.

Bath: Opening of Ultra-Violet Rays Department.—On May 16th the new ultra-violet rays department at the Royal Baths, Bath, was opened by Dr. Leonard Hill, who spoke of the now recognised value of artificial sunlight in combating the many ailments of our smoke-bound islands, and described the action of the ultra-violet rays. Speaking of the importance of sun and air in hospital treatment, Prof. Hill said the idea of a hospital of five or six stories was out of date. Hospitals should be built on the bungalow plan, where the patients could be run out on to a verandah or on to a grass plot. The Mayor of Bath, Alderman C. Chivers, J.P., presided at the ceremony and among the guests were many medical men. Councillor C. H. Hacker moved a vote of thanks to Dr. Hill, which was seconded by Dr. Gordon F. Thomson.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

CONTRIBUTORY PENSIONS BILL.

Mr. N. CHAMBERLAIN, Minister of Health, in moving the second reading of the Widows', Orphans', and Old Age Contributory Pensions Bill on Monday, May 19th, said it lay in the direct succession of a long line of measures passed during the past 30 years all founded on the fact that a state of society in which a large part of the population no longer themselves produced the necessaries of life, but depended on continuous employment in other occupations to obtain the means of purchasing—a state of society which involved constant menace and risk to the security of the worker—involved a corresponding need for providing against that risk. Every one of those Acts had been extended and expanded. Taking all those measures together, they effected in a short space of time a profound and revolutionary change in the status of the workers of this country. But there still remained one gap in the chain—one link missing, because although the widow of a man who had lost his life in pursuing his trade or occupation was now provided for, accidents of that kind were fortunately so rare that with the possible exception of the mining industry they hardly entered into the calculation of the ordinary individual. There was undoubtedly something very attractive in the idea that they should have one single contribution on one single card which would entitle the contributor to all the benefits comprised in the existing scheme of national insurance combined with workman's compensation, widows' pension, and old age pension at an earlier age. But though the Government had given serious and prolonged consideration to this point they had come to the conclusion that it was impossible to include workman's compensation. For reasons of economy it was obviously undesirable to set up new machinery, and the Government had chosen to link up the new scheme with health insurance chiefly on the ground that health insurance covered so much wider a field than unemployment insurance. And so the new scheme was interlocked with the National Insurance Act. They proposed to invite the assistance of the approved societies in providing certificates by virtue of which a man would become entitled to benefits. The pensions would be paid through the Post Office, and it was not anticipated that the cost of administration would be more than 2 per cent. of the contributions. Section 3 of the National Health Insurance Act dealt with medical benefits. Under that Act a person who was insured and had reached the age of 70 was entitled to free medical benefit for the rest of his life. But supposing he had only reached the age of, say, 65 and ceased to be employable, and therefore passed out of insurance, he lost the right to medical benefit. That was a considerable grievance, and the present Bill allowed that to be amended by providing that in future insured persons who reached the age of 65 would have the boon of medical benefit for the rest of their lives. The persons who were not insured at all were left out of the scheme not on any ground of principle, but because they could not find any way of fitting them in. It was estimated that in the first ten years the burden which this scheme would impose upon employers would amount to £10,250,000 a year, not a sum which he thought they would trouble about much if it stood by itself, but it had to be taken in conjunction with the already heavy burdens of taxation, Imperial and local, and all the other social services which they had to meet. But he believed that every employer would agree that the psychology of the workman had a very marked effect upon his output. If that were so surely employers ought to welcome this scheme which did so much to provide against one or more of those contingencies which were most dreaded by their workmen. This scheme would reduce unemployment by getting the older men and women out of industry. He had made inquiries and his department estimated that there would be an immediate relief to the rates of something like £3,000,000 a year which would gradually rise until it got to something like £7,000,000—a substantial relief. The Government's policy was to use the great resources of the State not for the distribution of an indiscriminate largesse, but to help those who had the will and desire to raise themselves to higher and better things. That policy was embodied in the Housing Act of 1923 and also in the present Rating and Valuation Bill, where for the first time they were trying to set up a standard by which they could measure the ability of local authorities to bear their burdens and the need they might have of assistance from the central authority. They would also find this principle in the measure which he hoped to introduce next year for the reform of the Poor-law, and for the more scientific and equitable distribution of public assistance.

Mr. WHEATLEY moved:—

"That this House, while it would welcome a just and generous scheme of widowed mothers' and orphans' pensions with a reduction of the age of qualification for old age pensions and the removal of the means limit, declines to give a second reading to a Bill which exacts contributions from wage-earners and imposes an additional burden on industry, makes no provision for a large number of widows and orphans and families where the father is incapacitated and, in the case of those qualified to become recipients, provides allowances which are wholly inadequate."

Speaking in the adjourned debate on the following day,

Lieut.-Colonel FREMANTLE said that while in the meantime he supported this magnificent measure of social reform he felt that they were wasting money by giving pensions rigidly to those who were 65 years of age. This point was likely to be of some importance in the future. The Government's Actuary's tables were based on the state of life tables and the mortality rates were diminishing every year. They were likely to go on diminishing for some time. In the course of the next 40 years the number of people between 65 and 70 years of age would have nearly doubled. Not only had the expectation of life increased, but the length of working life had also been increased. He foresaw a future time when people would live to 90, 100, or more. What was the position going to be then? The present pension scheme permanently threw people out of work at 65. He was sure that in future the pension scheme ought to be on a disability basis. Just as they had in the war disability decided by a board, so in civil life disability should be decided by a medical board, diluted by such other elements as might be required. It should, however, be a professional technical board to decide disability.

The amendment was rejected by 401 votes to 125 and the Bill was read a second time.

HOUSE OF LORDS.

TUESDAY, MAY 19TH.

Procedure in Coroners' Courts.

Lord DARLING raised the question of the procedure in coroners' courts and called attention to the not infrequent practice of holding inquests on the bodies of deceased persons simultaneously with the hearing by justices of charges against persons arrested and accused of causing the death of the same deceased persons. He suggested that if at any inquest the coroner was informed, before the jury had given their verdict, that some persons had been charged before the justices with murder or manslaughter of a dead person, then, in the absence of good reason to the contrary, it should be the duty of the coroner to adjourn the inquest. When the whole case had been thoroughly investigated and brought to an end, a merely formal meeting of the coroner and his jury would result in returning a verdict which would have no effect beyond regularising the proceedings.

The LORD CHANCELLOR agreed that a certain amount of mischief ensued at present in these cases, and as the practice was that one witness of the tragedy might have to give his evidence no less than four times, great expense was involved, while the case of the accused man was sometimes prejudiced because the inquest took place while the police court proceedings were going on. The Government proposed to introduce a Bill dealing with the whole question of coroners, and a number of other matters which had arisen in connexion with inquests. The Bill would be found to contain a clause very much to the effect suggested by Lord Darling. The Bill was ready, and was only awaiting approval by some local authorities in connexion with financial matters. He hoped that within a very short time the Bill would be introduced and passed into law.

HOUSE OF COMMONS.

WEDNESDAY, MAY 13TH.

Wages and National Health.

Mr. MORGAN JONES moved that, "in view of the practically universal acceptance of the principle that a living wage for all workers should be the first charge upon industry, and in view of the large measure of agreement with respect to the advisability of fixing legal minimum time rates of wages reached at the National Industrial Conference, this House urges the Government to proceed without delay with the Bill introduced by the Government of the day of 1919, constituting a commission to inquire into and report upon legal minimum time rates of wages."

Mr. JOHN BAKER seconded the motion.

Dr. HADEN GUEST, in supporting the motion, said he wished to place before the House certain purely medical considerations, certain considerations dealing with human life, and certain considerations dealing with wages which he suggested should be taken into account when considering how a minimum wage was to be calculated. They were all familiar with the appeals for funds made by the numerous hospitals in London. During the last few days they had been distressed to learn that the Middlesex Hospital was in a very bad position and needed a large sum of money. If they added to the money spent upon the voluntary hospitals the money spent upon Poor-law infirmaries and on medical relief through the Poor-law, and further the amount spent upon clinics of one sort or another, they arrived at a sum running into many millions a year. A large part of that expenditure was part of the price the country had to pay for compelling men to live on low wages. If hon. Members would go to Guy's Hospital, which derived a large proportion of its patients from occupations where there was casual employment and low wages, they would see how those people suffered directly from the effects of underpayment and insufficient food. In his own experience in connexion with school clinics in London he had found the same thing. The figures went down during the war because separation allowances were being paid and for the first time in their lives—and apparently for the last time—a large number of people were receiving regularly week by week a definite amount of money, with the result that there was a great diminution of illness among children and a consequent decrease in the cost of treatment by the London County Council, the largest educational authority in the country. A large amount of what was called mental as well as physical deficiency had its origin in poverty. Those mental and physical defectives, when they reached adult age, were in one way or other a charge upon the community. He did not wish to exaggerate or to suggest that all these cases were due directly to the underpayment of the fathers and mothers of the patients, but a considerable proportion undoubtedly were so. He judged that the country paid a great deal more for the cost of medical treatment year by year than would make up the wages paid in industry to a decent minimum wage. Some employers had good intentions, but other employers had anything but good intentions, and, what was worse, they were simply indifferent to the economic effect of their enterprises on the workers. He confessed that he never felt more revolutionary than when he went down to his own clinic in Blackfriars and saw the children coming up for treatment—children who presented the same kind of illnesses, malformation and bad development as when he began his work there 18 years ago. Those children had good fathers and mothers, so far as morals and care of their children were concerned, but they earned so little that they could afford but a bare minimum of room, and a bare minimum of food, and only just sufficient clothing to keep their children decent enough to send to school. Almost as regularly as they went to school such children had to visit a doctor for maladies which were absolutely preventable. Years ago the medical officer of health for Essex made a detailed investigation of the deaths from measles in the county, and he found that while that death-rate was high for the county as a whole it was confined to children of the working classes. The terrible death-rate from infantile illnesses, from tuberculosis, and generally the illnesses that were indices of poverty, fell almost entirely on the lives and homes of poor people who were underpaid under our present system. He hoped that the inquiry sought for in the motion would be granted, and that when it was attempted to define the level of a minimum wage consideration would be given to medical and physiological questions which men and their families required.

Mr. BETTERTON (Parliamentary Secretary to the Ministry of Labour) said that the policy of the Government was that they adhered to the principle that the gross evil of sweating must be prevented, and they endorsed the view reached unanimously by the Committee presided over by Lord Cave that the Trade Board system was necessary for this purpose. But while the Trade Boards Act would be extended it would only be extended to new trades where it had been clearly ascertained by systematic investigation that conditions of sweating prevailed. If powers were entrusted to any body of men, however faithfully they might attempt to discharge their duties, to fix a minimum wage for every industry in the country, so far from producing anything like contentment and peace it would produce an outcry and uproar of which they could form but a dim notion. In the view of the Government, therefore, it was impossible to accept the resolution.

The motion was rejected by 227 votes to 132.

Night-Work in Bakeries.

Lord HENRY CAVENDISH-BENTINCK asked the Minister of Labour whether the British Government delegates to the International Labour Conference at Geneva this month had been instructed to move an amendment to the present draft on night-work in bakeries that would enable them, if carried, to vote for the convention.—Sir A. STEEL-MAITLAND replied: The Government have tabled certain amendments to the draft convention on night-work in bakeries, and have informed the International Labour Office that subject to these amendments being carried they would be disposed to accept the Convention, provided they could be satisfied that the effect of its adoption would not be to cause an increase in the price of bread to the consumer. Since that time the Royal Commission on Food Prices has examined this question and in view of its findings the delegates will state that the Government is unable at the present time to ratify the draft Convention.

THURSDAY, MAY 14TH.

Coroners and Inquests on Motor Accidents.

Rear-Admiral BEAMISH asked the Home Secretary if he was aware that considerable dissatisfaction existed in consequence of inquests on persons killed by motor vehicles being held without a jury; and could he see his way to introduce legislation compelling coroners to empanel a jury at every inquest into the death of a person as the result of a road accident.—Sir W. JOYNSON-HICKS replied: The subject has engaged my attention, and provision will be included in the new Coroners' Bill.

Education of Blind and Crippled Children.

Mr. GROVES asked the President of the Board of Education the number of blind and crippled children, respectively, throughout the country for whom no educational provision is made; and what action he proposed to take with local educational authorities who refused to meet their obligations in this matter.—Lord E. PERCY replied: According to the returns of local authorities in England and Wales for the year ended Dec. 31st last, there were 567 blind children (including 287 partially blind) and 4301 crippled children (other than those suffering from active non-pulmonary tuberculosis) attending no recognised school or institution during the year. I may, perhaps, mention that large numbers of the crippled children not at present in special schools do not need to attend such schools, but rather require orthopædic treatment which will enable them to continue in attendance at ordinary public elementary schools, and I am taking all practicable steps to encourage the development of such treatment. As regards special school accommodation for blind and crippled children who need it, I have already asked all authorities to give their careful attention to the problem and to inform me what progress they are making.

Clinics for Physically Defective Children.

Mr. GROVES asked the President of the Board of Education the number of local education authorities who had not established clinics for the treatment of physically defective children; and what action he proposed to take if those authorities continue to refuse to make adequate arrangements.—Lord E. PERCY replied: Out of 318 local education authorities only seven have not yet provided any school clinics, and of these seven, five have submitted proposals which are now before my department. One of the remaining two cases is that of a small area where no clinic is required, and in the other case the authority have been requested to give the matter their urgent attention. I do not, of course, desire to suggest that in all cases the arrangements made in this respect are entirely adequate.

Mr. PALING asked the President of the Board of Education what provision was made by the West Riding (Yorks) county council education authority for the training of mentally defective children of school age; and whether such provision was sufficient to meet the needs of the area.—Lord E. PERCY replied: According to returns furnished by the West Riding local education authority for the year 1924, there were in the area 528 children ascertained to be mentally defective within the meaning of the Education Act, 1921. The local authority have no school of their own for mentally defective children, but they have sent 23 children to special schools certified by the Board.

X Ray Examination and National Insurance.

Mr. BASIL PETO asked the Minister of Health whether his attention had been called to the fact that the assistance of X ray examination was not one of the benefits provided under the National Health Insurance Act; and, seeing that this was now essential to correct a diagnosis in many cases, and in view of the fact that the development of radiography was approximately coeval with the Act, he would amend the Act to give the advantages to insured persons. Mr. SMITHERS asked the Minister of Health a similar question.—Mr. N. CHAMBERLAIN replied: Payment for an X ray examination can at present be made under the National Health Insurance Act only where the examination is incidental to a service, such as dental or hospital treatment, made available to members under an approved society's scheme of additional benefits. The question of any extention or development of the benefits of the Act is now under consideration by the Royal Commission on National Health Insurance to whom I am forwarding my hon. friend's suggestion.

Butter for Asylum Inmates.

Colonel Day asked the Minister of Health whether he was aware that the Metropolitan Asylums Board had recently decided to discontinue the supply of butter to inmates during the summer months on the ground that, whilst butter contained the vitamins necessary for bodily health, this form of food was to be omitted during the summer months as sunshine supplied the vitamins required; and would he recommend that the allowance of butter be continued irrespective of season.—Mr. N. Chamberlain replied: I am advised that the use of margarine is quite compatible with a good diet, provided that the other constituents of the diet are satisfactory; and that the dietary adopted by the Metropolitan Asylums Board satisfies this condition, and further makes adequate provisions for adjusting the diet to suit the needs of any particular case. In these circumstances, I could not properly intervene in the manner suggested.

Inequalities in Insurance Benefits.

Mr. Kelly asked the Minister of Health if he was aware of the inequalities which would arise on July 6th, 1925, as a result of the division of the valuation of approved societies under the National Health Insurance Acts into two sections, whereby that section whose valuation took place in 1922 would be in a position to distribute additional benefits, if any were due, to their members a year in advance of the societies valued in 1923; and could the question be considered of postponing the coming into operation of the additional benefits declared in respect of societies valued in 1922, so that all additional benefits of all societies would come into operation on the same date, thus removing inequalities.—Mr. N. Chamberlain replied: Such inequalities as are suggested in the question are merely temporary, and the present arrangement has been agreed to by the consultative council which is representative of approved societies as being the best method of procedure and for the valuation of some 9000 societies and branches. As regards the second part of the question, the work in connexion with valuation and the preparation of schemes by approved societies necessitates an interval of 2½ years to elapse between the date of valuation and the date on which members begin to enjoy the additional benefits provided as the result of the valuation, and I do not think it desirable that this interval should be prolonged by another year.

Pay of Officers in the R.A.M.C.

Colonel Day asked the Secretary of State for War whether any difficulty had been found in recruiting doctors into the Royal Army Medical Corps on account of the poor rates of pay offered qualified medical men; had any increase on the standard rates now operating been considered; and, if so, what was the scale of pay suggested.—Sir L. Worthington-Evans replied: The number of candidates for commissions in the Royal Army Medical Corps has declined owing to a variety of causes. Proposals regarding the rates of pay of medical officers are being considered, but I am not at present able to give details.

Monday, May 18th.

Pay of Medical and Dental Officers in India.

Major-General Sir Richard Luce asked the Under Secretary of State for India if the married officers of the Royal Army Medical Corps, the Royal Army Veterinary Corps, and the Army Dental Corps, serving in India, were still excluded from the increased pay and allowances, including quarters, recently granted to other branches of the British Army, by which exclusion a major of the Royal Army Medical Corps received 75 rupees per month less than a senior captain of the Royal Engineers, and five rupees less than a captain of the Royal Army Service Corps; and if he would assure the House that members of these three services would not eventually suffer by reason of the delay involved in the consideration of their case.—Earl Winterton replied: The case of the services mentioned has been reserved for separate consideration in view of the possibility of changes affecting them in the near future. If the examination of the cases reveals sufficient grounds, increases will be given from such date as may be appropriate.

Statutory Vaccination Declarations.

Mr. Groves asked the Home Secretary if his attention had been called to the refusal of certain magistrates to witness statutory declarations under the Vaccination Acts; and would he follow the precedent of one of his predecessors and circularise all magistrates, calling their attention to their legal obligations to witness statutory declarations when sitting in open court, and expressly pointing out to them that they were neither required nor authorised to cross-examine applicants as to the reasons for their objections but that their conscientious objections were sufficient.—Mr. Locker-Lampson (Under Secretary to the Home Office) replied: Yes, Sir, on March 17th my right hon. friend received a deputation from the National Anti-Vaccination League which made representations to him on the subject. After carefully considering the particulars submitted by the League, he came to the conclusion that no case had been made out for the issue of a circular to justices. The Home Secretary does not, therefore, propose to issue one.

Tuesday, May 19th.

Danger of Infant Foods.

Mr. Groves asked the Minister of Health whether he would consider the possible danger to infant life arising from the sale of proprietary infant foods consisting largely of starch and flour; and whether he would introduce regulations governing the sale of such foods, in view of the fact that he had issued instructions controlling the sale of dried milks.—Sir Kingsley Wood replied: My right hon. friend is sure that misleading claims are sometimes made as to the value of infants' foods, consisting largely of starch, but he is not satisfied on the information at present before him that there is sufficient evidence of danger arising to public health to justify the issue of regulations at the present time.

Mr. B. Smith asked if the hon. gentleman would circulate through the medical side of the Ministry of Health the names of the applicants who largely embodied starch in so-called foods.—Sir Kingsley Wood replied: I do not see the necessity to do that. The consumption of these proprietary foods is decreasing.

The Sale of Patent Medicines.

Colonel Day asked the Minister of Health whether his attention had been drawn to the dangers arising from the unrestricted sales of certain patent medicines, where the manufacturers were not compelled to state the composition of the products bearing their labels; whether he proposed to take any action in the matter to further protect the public; and would he introduce legislation to compel all manufacturers of patent medicines to state plainly on the labels of medicines sold the ingredients contained in them.—Sir Kingsley Wood replied: My right hon. friend fully appreciates the importance in the interest of public health of securing some statutory regulation of the conditions under which patent medicines are advertised and sold, but in the present state of business he does not anticipate that it will be possible to introduce legislation on this subject during the present session.

Panel Doctors' Fine —Our Manchester correspondent writes: The decision of the Ministry of Health to waive more than half of the fine of £1000 imposed on two medical men at Tottington, Lancs, for breaches of the panel regulations has produced a good impression here. It is understood that £450 has already been deducted from the quarterly remuneration of the doctors in payment of the fine. The Ministry, in intimating its decision to the Lancashire Insurance Committee, states: "Regard has been paid to the fact that the practitioners have expressed regret for the breach of the terms of service and have undertaken to observe them carefully in future. Also weight has been given to the consideration that the action taken in this case has been sufficient to make clear the very serious view taken of the practice of charging fees to insured persons for treatment which practitioners are bound to render free of charge."

International Congress of Radiology.—The preliminary programme for this Congress, which will be held in London from July 1st to 4th, has reached us. The number of papers to be read is large and the list of those taking part is representative of workers in all countries. The work of the Congress will be divided into three sections —namely, radiology, physics, and electrotherapy and physiotherapy. The radiology section will probably meet in two parallel sessions each day, the subjects for this purpose being divided into those bearing on diagnosis and those bearing on therapy. On the opening day the sections of radiology and physics will meet in joint sessions for a discussion on the standardisation of dosage, which will be opened by Prof. W. Bragg from the physical standpoint, and by Dr. Béclère, of Paris, from the medical. On the evening of that day the Silvanus Thompson Memorial lecture will be delivered by the Duc de Broglie, of Paris, his subject being Absorption of *X* and *Y* Radiations and the Secondary Radiations which Accompany Them. On the second night a Congress dinner will be held, and on the third night Sir Berkeley Moynihan will deliver the MacKenzie Davidson Memorial Lecture, his subject being the Relationship of Radiology and Surgery. Further details will be published shortly.

Notes, Comments, and Abstracts.

THE AUXILIARY HOSPITAL.

ITS FINANCIAL ASPECT AND THE EXTENT TO WHICH IT CAN RELIEVE PRESSURE UPON PARENT HOSPITAL BEDS.*

BY F. N. KAY MENZIES, M.D., F.R.C.P. EDIN.,
DIRECTOR OF HOSPITAL AND MEDICAL SERVICES,
JOINT RED CROSS COUNCIL;
AND
R. H. P. ORDE, B.A.

THE outstanding characteristic of an auxiliary hospital (or recovery home) by contrast with what we may conveniently call the parent hospital is that it is an institution to which patients can properly be sent for whom it is no longer necessary and, in fact, uneconomic, to continue under treatment in the parent hospital; but who for medical reasons are unfit to be sent either to a convalescent home or their own homes. Generally speaking, auxiliary hospitals are best situated in the country or at the seaside, and are much less costly from the point of view of buildings, staff, equipment, and cost of maintenance than the parent hospital; although, on the other hand, for similar reasons, they are more costly in all these respects than what are commonly called "convalescent homes."

The type of patient to be admitted to such an institution is illustrated by the schedule of cases. Out of a total number of cases transferred (402) from a parent hospital during the months December, 1924, and January and February, 1925, we have selected the following as typical:—

Pneumonia	33	Nephritis	9
Alimentary ulcers:		Rheumatism	9
Gastric, pyloric, duodenal	24	Gall-bladder	8
Appendicitis	66	Wounds and bruises	7
Heart conditions	16	Fractures	9
Debility	7	Gynæcological	23
Gastritis	7	Ear, nose, and throat	42
Tuberculous	15	Eye	13

Reported Shortage of Hospital Beds.

Practically every local voluntary hospital committee in England and Wales has reported that additional voluntary hospital accommodation is needed, although, as might be expected, the kind of institution and the additional number of beds required, as well as the type of disease for which there is a deficiency of accommodation, vary very considerably. The outstanding fact which emerges from a consideration of all these reports is that some thousands of additional hospital beds are said to be required in England and Wales, taken as a whole. It is surely well worth while making careful inquiry into the question as to which is the cheapest way in which this additional accommodation can be provided from the point of view of: (*a*) Capital expenditure; (*b*) cost of maintenance; (*c*) the best interests of the patient. A number of witnesses giving evidence before the Scottish Commission have recommended the provision of auxiliary hospitals, in order to relieve the pressure upon the parent hospitals. On the other hand, in England one of the largest and most important of the local voluntary hospital committees has expressed the following view:—

> The provision of recovery beds, where patients receive hospital treatment and not convalescent home treatment, does increase the number treated, to approximately the same extent as the provision of an equal number of additional beds on the site of the parent hospital. The idea that extension by recovery beds is cheaper than extension by hospital beds rests almost wholly on an illusion. Recovery beds may cost £2 2*s.* a week, while beds in the parent hospital cost £5 5*s.* a week. But this is only because the cost of a hospital bed, where there are no recovery beds, includes all the stages of treatment, whereas, if there is a recovery branch, the hospital beds are confined to the more expensive stages and the recovery beds to the less expensive. Thus, if the cost of the single institution averages £4 a week, this is made up of so many days averaging (say) £6 a week, so many averaging £5, so many averaging £3, and so many averaging £2. If the whole of the days averaging £3 and £2 a week are spent at a recovery branch, the average cost at that branch may well be between £2 and £3 a week, while the average cost at the parent hospital rises to between £5 and £6. But this does not mean that the combined average cost has altered in the least.
>
> There may be a saving in capital expenditure and in some items of maintenance, but, on the other hand, there will be some extra cost of separate administration and of transport.
>
> The advantage of a recovery branch, as compared with extension on the hospital site, lies, therefore, solely in the benefit to the individual patients, not in any increase in the number treated for the same amount of money.

It will be seen that this Committee is of the opinion that altogether apart from questions of capital expenditure and extra cost of separate administration and transport, there would be no economy in so far as *maintenance* is concerned, if the additional hospital accommodation needed is provided by means of auxiliary hospitals rather than by the addition of a similar number of parent hospital beds.

Real and Apparent Shortage.

Before considering the comparative cost of maintenance, there are two important questions which should be borne in mind, viz.: (1) To what extent are beds in parent hospitals now occupied by patients who have reached a stage in their treatment when they may be expected to progress towards recovery equally well, if not indeed more rapidly, at auxiliary hospitals situated in the country or at the seaside. (2) To what extent would there still be a real shortage of beds in our parent hospitals, if all those patients found suitable on medical grounds for transfer to auxiliary hospitals were so transferred at the earliest possible date.

These two questions must be answered before even an approximate estimate of the real shortage of beds in our voluntary hospitals in this country can be arrived at.

There should be no difficulty in arriving at an answer to the first question. If a careful investigation of all the beds occupied in our general and special hospitals were to be made by competent persons, it would be found that there are always some beds occupied by patients for whom the parent hospital has done all that can reasonably be asked of it. They have not been discharged for one of two reasons: (1) The patient is not yet really fit enough to go direct home or to a convalescent home; (2) there is no other suitable institution to which the patient can be sent, for the convalescent home, as a rule, is not built, equipped, or staffed in such a way as to be able to relieve the parent hospital of the type of case at the stage of treatment which we have in mind. If then it be true that there is a certain wastage or uneconomic use of beds in the parent hospitals, and this wastage can be reduced by the provision of an equally suitable type of institution, called an auxiliary hospital, then it is surely of first-rate importance to make a careful inquiry into the accuracy of the statement that "the idea that extension by recovery beds is cheaper than extension by hospital beds rests almost wholly on an illusion."

The second question is more difficult to answer. In each area the conditions vary sometimes considerably and calculations based upon 2, 3, or 4 beds per 1000 of the population have a very limited value. Waiting lists, however carefully kept, although useful, cover a comparatively small portion of the ground. Experience has taught us all that in cases where additional hospital accommodation of one kind or another is provided, a most surprising demand for such accommodation springs up from all kinds of unexpected quarters. Consideration also has to be given to the extent to which public health authorities and Poor-law guardians in various parts of the country are fulfilling their statutory obligations.

Is the Alleged Economy of Recovery Beds Illusory?

Is it true to say that the idea that extension by recovery beds is cheaper than extension by hospital beds rests wholly on an illusion? This is the considered opinion of a committee which represents an area containing some 12,000 to 13,000 beds, and in which there is an estimated shortage of 2000 beds. There are two methods under consideration, by which this shortage can be met: Scheme A—By adding, to the existing hospitals, wards containing beds to the required number. Scheme B—By providing 2000 beds in homes of recovery in neighbouring country districts.

[The authors here examine these alternative methods in some detail and conclude:]

It appears from the figures we have obtained, that the effect of converting 15 per cent. of the beds of a hospital from a three-week to a two-week service upon the average weekly cost of each patient is by no means so great as is suggested in the paragraph which we have quoted. If our conclusion is correct and we apply it to the area in question, the costs under Scheme A and B work out in this way:

					Per week.
Scheme A.					
13,000	existing beds.				
2,000	additional hospital beds.				
15,000	at average cost of £3 per patient per week				£45,000 0 0
Scheme B.		£	*s.*	*d.*	
13,000	existing beds at a cost of £3 1*s.* 1½*d.* per patient per week	39,731	5	0	
2,000	beds in recovery homes at £2 per patient per week	4,000	0	0	
					£43,731 5 0
	Or a weekly saving of				£1,268 15 0

Equal to £65,975 per annum.

---

* Abstract of a paper introducing a discussion at the Annual Congress of the Incorporated Association of Hospital Officers on May 15th.

If in place of a weekly average cost of £3 in the main hospital, a weekly average cost of £3 10*s.* is assumed, the saving on Scheme B as compared with Scheme A amounts in each week to £2214 11*s.* 8*d.*, or £115,158 6*s.* 8*d.* per annum. Such data as are available tend to show that there is at least prima facie evidence in favour of the "idea" which has been described as illusory. We are indeed unable to accept the view that expenditure at a parent hospital rises with the rapidity of the passage of the patients through its beds, at such a rate as to balance the lower cost of the beds in an auxiliary hospital. We hold that the unavoidable expenditure, at every large and expensively staffed and equipped general hospital, that is altogether independent of the stage of treatment of a patient, or even of the occupation of the bed at all, far outweighs any differences in cost between first, second, or third weeks of treatment. At the same time, even if it should be true that the "idea" to which we have so often referred, rests on an illusion, it by no means follows that extension by auxiliary hospitals is an economically illusory proposition.

The Economic Use of Parent Hospital Beds.

It has been well said, by the committee already referred to, that "the addition of a recovery branch centres in the parent hospital a larger number of patients who need expensive methods of diagnosis, operations, and other early stages of treatment, and thus enables fuller use to be made of the highly specialised staff and apparatus, thereby reducing cost and increasing efficiency of service. But this result is only produced if the staff and apparatus are not already fully employed, and in that case would be produced by the addition of beds on the hospital site."

What meaning, however, are we to attach to the words "fully employed"? for upon this depends almost entirely the case for or against the auxiliary hospital. The modern parent hospital is so situated, built, staffed, and equipped that cost is only reduced to a minimum and efficiency raised to a maximum when it is engaged upon work of a highly specialised character. Any individual bed, therefore, occupied by a patient who no longer requires the services which only such a hospital can give is being used uneconomically. The bed is employed, it is true, but not *fully employed* in the economic sense. Can it be said of any large general hospital that there are no patients in its beds who could not, without detriment to their treatment, be transferred to auxiliary hospitals if such existed?

In the 12 large general hospitals in London with medical schools, the average number of days each patient was resident during 1923 was 19·57, and the variations ranged from 26·40 to 14·41. It is noteworthy that at the hospital in which the average stay was 14·41 a recovery branch has been established, and that the combined cost per occupied bed at this hospital and its home of recovery is nearly £3 a year lower than at the parent hospital itself.

In the 14 provincial hospitals with medical schools, the average length of stay of a patient varied during 1923 from 27·98 to 15·05 days. It is a fact that at the hospital at which the stay was 15·05 days, a return was made of the total number of days of residence of seven long-stay patients. This total was equal to the time necessary for the treatment of 40 patients suffering from hernia or hæmorrhoids. The long-stay patients were retained because there was no accommodation available to which they could be sent, and for no other reason. It is hardly possible to imagine a more uneconomic use of parent hospital beds.

In Scotland, at the six large hospitals with medical schools the average length of stay of a patient varied from 25 to 20·29 days.

The character of the work undertaken at these large hospitals throughout the country and the scale upon which they are staffed and equipped, does not explain the variations in length of the patient's residence. Even if we assume that at those hospitals in which the average stay approximates two weeks the staff and apparatus is already fully employed in the true economic sense, we cannot assume the same with regard to those at which the length of stay is a week or 12 days longer. Indeed, it is common knowledge that even at the busiest hospitals a surgeon frequently retains a patient in his ward simply because there is no suitable accommodation to which he can be discharged, and not because to admit another patient in his place would be to throw too great a load upon himself or the staff of the hospital.

The economic use of operating theatres, such as are provided at all large parent hospitals, is limited by the number of beds available for patients operated on, and if any of these are occupied by those who could be transferred to a recovery branch, the theatre is not being used to its fullest possible extent, and so with all the other specialised buildings and departments. When the point has been reached, by means of recovery branches, at which the beds of a parent hospital are being used to their fullest extent for the purpose for which they are best adapted, then it is time to develop and extend wards, operating theatres, and other special departments. It can never be an economic proposition to add beds to the parent hospital and utilise them for the retention of patients a moment longer than is absolutely necessary. And we are of opinion that this is the true test of whether, in any given locality, extension should be by way of recovery branches or by way of beds at the parent hospital.

WOMEN'S HOLIDAY FUND:

WANTED A NEW HOLIDAY HOME.

To the Editor of THE LANCET.

SIR,—We make an earnest appeal to all concerned with the health and welfare of the coming generation to help the Women's Holiday Fund to raise the sum of £4000–£5000, necessary for the purchase and equipment of a house to be used as a holiday home for mothers and babies. The Women's Holiday Fund have recently had to terminate the lease of their home at St. Leonards-on-Sea, and are anxious now to buy a house, so as to start a permanent home for what is an important part of their work. All social workers know only too well how often a tired ailing woman has to drag on uncomplainingly at home, when a fortnight's change with good food and fresh air would restore her to health. They also know how difficult it is to secure vacancies at the homes, where not only can such cases be received at a moderate charge, but where the mother and baby are specially cared for—with such excellent results. Donations may be sent to the Secretary, Home for Mothers and Babies, Women's Holiday Fund, 76, Denison House, 296, Vauxhall Bridge-road, S.W. 1.

We are, Sir, yours faithfully,

MARY FITZALAN.
JESSIE P. B. PHIPPS.
MARION VAUGHAN.
HELEN A. POWNALL,
Chairman of Executive Committee.

May 18th, 1925.

A MEMORIAL TO MRS. R. P. WETHERED.

A COMMITTEE has been formed to raise a sum of money to be expended in placing a tablet to the memory of Mrs. R. P. Wethered in St. James's Church, Paddington, which she attended, the surplus to be used in furtherance of the work to which she devoted her life. When Mrs. Wethered died last year, the cause of rescue and preventive work among young persons lost one of its most enthusiastic supporters. For more than 40 years she had laboured unceasingly to save young girls from drifting into evil ways, to raise and elevate the fallen, and to restore those diseased to health and efficiency of mind and body. Subscriptions, large or small, may be sent to the Treasurer, Mr. E. B. Turner, F.R.C.S., at Victoria House, 117, Victoria-street, S.W. 1.

PROSTITUTION IN INDIA.

DURING recent years a certain number of educated Indians who have become imbued with Western ideals have expressed themselves as hostile to the practices which tend to popularise the prostitute's profession. In a recent book on "Crime in India" (Humphrey Milford. 1924. Pp. 169. 8*s.* 6*d.*) Mr. S. M. Edwardes, who was a Commissioner of Police in one of the most important urban forces of India, discusses both the historical aspect and the present-day position of prostitution which, although not strictly a criminal offence, is yet closely connected with crime and police work. There exists in the first place a form of prostitution connected with the traditions and customs of certain religious sects and side by side with this ordinary commercial prostitution is notoriously rife. The ordinary type consists of two varieties: that carried on by Indians and that by European prostitutes, usually of Russian and Eastern European origin. There was at one time in India a Contagious Diseases Act, under which the Indian Government exercised a certain amount of supervision over prostitution, but this was repealed so that no official statistics as to the extent of the practice are available. India has been represented at various conferences held under the ægis of the League of Nations with regard to the traffic in women and children and has actually assented to the fixing of the age of consent at 21. Various private Bills on this matter have been presented to the Indian legislature and it remains to be seen how the politicians will deal with the demands of recent Indian opinion for the restriction of purely commercialised vice, while permitting hereditary harlotry and religious prostitution under the Hindu caste system.

Dr. F. W. Pilkington would like to know of a private home or institution where an elderly lady, infirm, but not mentally afflicted, can be boarded and lodged for £1 weekly.

A Standard Translation of Freud

COLLECTED PAPERS ON PSYCHO-ANALYSIS.

By SIGMUND FREUD.

Vol. III. Case Histories. 30s.

Perhaps the most important of all Freud's published works. It contains his detailed analysis of five case-histories, and has never before been translated into English.

Some Press Opinions on Vols. I. & II. :—

The Lancet :—"These volumes may . . . be studied as a record of history in the making."

The Nation and Athenæum :—"It is a great satisfaction to have, for the first time, a really good translation of the long series of contributions in which Freud has gradually built up during more than thirty years the imposing structure of psycho-analytic theory."

The Spectator :—"This is one of the most valuable translations of Freud's work : it gives an opportunity of seeing the gradual formation and confirmation of his views."

A Clinical Lecture

ON

BLOOD PRESSURE:

ITS RELATION TO THE TREATMENT AND DIAGNOSIS OF VERTIGO AND TINNITUS.

Delivered at University College Hospital Medical School on May 14th, 1925,

By RICHARD LAKE, F.R.C.S. Eng.,
G. E. DUVEEN LECTURER ON OTOLOGY, UNIVERSITY OF LONDON.

The effect of the blood pressure upon the symptoms of vertigo or tinnitus—and one may here remark that what applies to these two symptoms may be applied even more widely to deafness—is a matter in which I have been much interested for many years, more especially in the first instance in vertigo, as the amount of incapacity caused thereby is so frequent and so severe. In 1912 I compiled a classification of cases of aural vertigo. Amongst these were: Aural vertigo due to altered states of the blood pressure: (*a*) increased blood pressure, and (*b*) diminished blood pressure.[1]

At that time I was under the impression that increased pressure was the commoner condition. Now, however, I am sure that it was partly my ignorance of the proper technique, and partly preconceived opinion that were the causes of my assuming results which now I am convinced were wrong. After a while I got into the habit of always sending my patients, whenever possible, to a skilled observer. The mercury sphygmograph made a great improvement possible in the accuracy of observation—still, I think that the stethoscope should be used in all cases to obtain the best results. At this time we were obsessed as well by a supposed condition called increased intra-labyrinthine pressure, a condition which, without much risk, I think we can say has yet to be proved to exist. The paralysing effect of such, or any, unsupported explanation on research is really serious. And seeing this, I feel that it will be better if my present contribution is received with, to say the least, reservation.

Treatment of Vertigo and Tinnitus.

A few words as to the operations I was largely instrumental in introducing for the relief of vertigo and tinnitus. Some of my colleagues generously sent their cases to me thinking that some more uniform result would be obtained if the material were in the hands of one rather than many, and that also more definite indications for operation would result. Altogether, since 1904, I have done 19 operations for vertigo with one death; the result was good and I do not think that a death should ever occur. A good example of the beneficial effects of the operation for vertigo is a patient (reported by me previously as No. 8)[2] who commanded a Territorial regiment in India throughout the war.

Turning to operative treatment for the relief of tinnitus one forms a totally different opinion. In 1909 I stated that in my opinion operations for tinnitus never ought to be done,[3] and that is my opinion to-day, absolutely without qualification.

I think it is more rarely now, with our present knowledge, that it is necessary to operate on vertigo. Relatively, it is also seldom, I am thankful to say, that the adviser is unable to give relief to the sufferer from vertigo, although I regret to say relief is not so frequent with regard to those suffering from tinnitus. Above all, when one has any evidence of neurasthenia, we must be very careful never to suggest operation. A few years ago, my colleague, Mr. Tilley, asked me to see a patient with severe tinnitus. I treated him off and on for some time, but with little effect—he was a confirmed neurasthenic. He implored me to operate, which I refused to do, but then came to me and said he had been to see two other aurists who both wished to operate. I besought him to be advised by me, and to have nothing done, as he not only would derive no benefit, but rather would be worse from the effect of the disappointment. Unfortunately, however, he preferred to attempt to obtain the impossible. Later on he wrote to me, as he had already promised he would do in the event of his submitting to operation, confirming my pessimistic view.

These two symptoms, vertigo and tinnitus, occurring in many diseases besides aural ones, have one great point of difference in the latter. The former, except in suppurative disease of the middle ear, is more often central, while the latter is, at least in earlier periods of life, most frequently due to a peripheral irritation.

Past and Present Methods.

In considering the treatment of these conditions it is well to revert to the methods of 20 years or so ago. This especially applies to tinnitus. When a patient complained of tinnitus, the aurist, who at that time had but little to guide him in the pathology of the condition, was in the habit (presuming others behaved in a more or less similar way to myself) of using four or five drugs, purely empirically. We got good results, or bad results, or no result at all, but never was one able to arrive at any clear indication to assist in giving any *special* treatment in any *specific* case. Now, however, things are certainly improved. We know much more about the origins and causations of these two symptoms. We know more about the pathology, infinitely more about the physiology, and a great deal more about the effect of drugs and treatments.

If we consider vertigo, we notice that, except in suppurative disease, it is uncommon before adult life; that is, in the earlier years—up to 25, we will say—it appears to be almost always the result of middle-ear disease. When it occurs in early adult life and onwards to old age, it appears to be practically invariably the result, either of changes in the arterioles or of the effects in the general circulatory system caused by disease or drugs.

The treatment of vertigo in the relatively young adult requires a very careful study of all possible contributory factors, and here, as well as in later life, a careful estimation of the blood pressure may be of great assistance. Of other contributory factors which may be present, sepsis, tendency to neurasthenia, and any coexisting disease of the ear are the chief. It is only when we are unable to give relief that operation is called for, and even then operation should only be resorted to when deafness is of so high a degree that the ear is useless.

When one comes to study and deal with cases of vertigo occurring in ordinary non-suppurative middle-ear disease, or in cases where there is no obvious middle-ear disease occurring towards the prime of life or later, there are certain conditions which will prevail. One of the most frequent is that there is an abnormal state of the blood pressure. Another one is that not infrequently the patients have a fixed malleus and an obstructed nose, and have been in the habit of using great violence in blowing the nose. In such a case there will be a very lax tympanic membrane. This laxness is rarely found without pre-existing fixation of the malleus, and is caused, as is sometimes vertigo, by violent distension of the middle-ear through the forcible nose-blowing; then merely ceasing from violent nose-blowing will, in many cases of itself, cause the disappearance of the vertigo. Correction of the nasal obstruction is necessary for permanent relief.

The Interpretation of Blood Pressure.

With regard to blood pressure what has to be said will apply equally to tinnitus and to vertigo. We can, for the sake of argument, consider that blood pressures may be divided into three main categories: above the average, the average, and below the average—the average being that termed the normal blood pressure, but the word normal here means the mean or average blood pressure of a large number of people in good health. Therefore, there must be a smaller proportion than the average who have a blood pressure above the average; the same applies to the low pressure, and, I think, it is the generally accepted fact that the lower blood pressures are people who, given the opportunity, live the longer.

---

[1] The Lancet, Dec. 14th, 1912.
[2] Ibid., June 10th 1911.
[3] Brit. Med. Jour., Oct. 16th, 1909.

The relative importance of the height of the blood pressure is probably, as far as I can see, more difficult to ascertain and determine during that period of life in which an early arterio-sclerosis shows itself, and it is there that a correct interpretation of the value of blood pressure shows the skilled physician. I think it is acknowledged that when arterio-sclerosis commences the blood pressure steadily rises, and that this will continue rising to a high grade from the individual's normal, but will, in a proportion of cases, later on begin to drop, and may fall very low.

When we find in an adult that the blood pressure is considerably below normal, and this in a person who suffers from vertigo, it is well to attempt, at the commencement, to raise that blood pressure towards that to what is assumed to be the normal, but it has always seemed to me that from 10 to 12 per cent. is as much as we should endeavour to raise it, for in these people it is probably normal at but little above 120 at the age of 45. Here one finds the most extraordinary effect of tobacco-smoking. If the blood pressure is low after the age of 40, tobacco-smoking appears to me frequently to have the effect of causing vertigo. When this is the case the mere abstention from the drug affords relief from the symptom which lasts as long as that abstention is observed.

One of the chief characteristics of the vertiginous attacks due to subnormal states of the blood pressure is the period in the 24 hours during which many of the attacks have occurred. The patient wakes up giddy, attempts to get up, and is generally obliged to return to bed and there stay for a period of time which may last from a few hours to several days. This condition seems to be generally attributed to bilious attacks, and I do not see quite how we are to separate them, as at any rate, personally, I am quite ignorant of what a bilious attack is. Sweating occurring after the attack I have also noted, but by no means constantly. As for the direction attributed to the movements of particular objects, certainly in a large proportion of cases there is no specific direction observed, but the fact that there is a specific direction does not seem to be of any importance. Of course, one comes upon a certain number of people who think that they are giddy when only experiencing a tendency to faint, and they always will answer in the affirmative when asked if everything goes black when the attack occurs. Actual vomiting, I should say, is uncommon, though nausea, even severe, is generally complained of in vertiginous attacks with low blood pressure.

A high blood pressure is, I think, extremely rare in cases of vertigo, and I am inclined to think that it is on account of the fact that when the intercranial arterial pressure is raised high enough to possibly cause a vertigo, that symptom is missed in the general physical disturbance. Still, vertigo does occur, though very rarely, in association with a high blood pressure. One of the rare instances in which I can recall high blood pressure with vertigo was due to sepsis derived from pyorrhœa. This was the case of an extremely vigorous woman of some 50 years of age, and she was immediately relieved of her vertigo when the oral sepsis was cured. High blood pressure in cases of vertigo is so rare as to be almost negligible. It is only when we find the blood pressure of a person suffering from vertigo is not subnormal, but practically the average, that there is any serious difficulty in arriving at the causation, when we seek the assistance of a skilled physician who can inform the aurist whether arterio-sclerosis is commencing or not, and if the patient, who would in health have had a low pressure is now developing an average blood pressure, —i.e., a raised one for him.

Excessive Reduction of Blood Pressure as a Cause of Vertigo.

I have twice been consulted by people, one of either sex, who had each been under a physician for the purpose of having a too high blood pressure reduced. The physician had in each instance been, from his point of view, successful. What the two medical men thought of my request that they would allow the pressure to go up again I never knew. Both of them were kind enough to accede to my request, to the patients' immediate relief from the vertigo. And there is no doubt that such or similar effects occur as the result of disease.

With regard to the treatment of vertigo, where relief is not obtained either from the cessation of violent nose-blowing, or from the discontinuance of tobacco, there are many drugs which will raise the blood pressure. I did all my early work with the derivations of ergot. There is a form of medication which is at the present time very much before us, I refer to the use of the endocrines, and I am convinced that in the administration of the correct combination of certain of these products the best method of treatment may lie.

TINNITUS AND ITS TREATMENT.

Tinnitus, in contradistinction to vertigo, was, during what I may term the empirical age, perhaps the more successfully treated. It is always well, I think, to confess even in public the error of one's ways, and it was my habit in those days to have five, I think it was, prescriptions, and my tinnitus cases ran the gamut, unless they were fortunate enough to get early relief. Even then I was quite convinced that the best drug, taking it all round, for the treatment of tinnitus was dilute hydrobromic acid, but of the why or wherefore I was ignorant, nor had I any definite reason for giving it in any particular case. We have here two totally different causations. In early life, and occasionally later, peripheral irritation is the direct cause of tinnitus. We may have an acute obstruction of the pharyngeal end of the Eustachian tube, caused by a little inflammatory condition, due to colds, and so forth. It is also occasionally kept up by a more or less chronic stricture of the tube. I have relieved an early tinnitus by injecting into the inner end of the Eustachian tube a very minute quantity of glycerin. acid carbol., not only may the tinnitus be stopped thus, but, if so, it is stopped instantly. Naturally, these intertubal injections are not capable of being handled without experience. Nor must the amount blown into the tube exceed at the outside one minim, and very gently, for it is perfectly extraordinary how much evil may result from what should be a perfectly safe procedure.

Fixation of the Stapes.

Leaving now tinnitus in the young, or tinnitus as a result of inflammatory effects of the nasal pharynx, we come to that variety of tinnitus due to middle-ear disease where there is fixation of the stapes, and in these cases the symptom is particularly difficult to treat. I have seen it due to an adhesion of the tympanic membrane and the stapes head, which was relieved by a division of the tiny adhesion. Tinnitus due to fixation of the stapes and the oval window is the most obstinate and resistant of symptoms, and it is here that empiricism is still paramount; I will not recapitulate the drugs which have been recommended, for you will find them enumerated in every text-book upon the subject. Here I think the value of acid hydrobromic dil. and valerianate of zinc in doses of 5 to 7 gr. (three times daily) should be tried. But when we come to consider the tinnitus rather as the disease and not the symptom, by which I mean the case of a person who consults the aurist for noises in the head, and whose auditory powers are practically unaffected, we obtain a blood-pressure picture the absolute opposite of what is found in vertigo. The blood pressure in tinnitus cases over middle age is much more often above than below the average, and must be primarily entirely due to a central nervous disturbance. Here then is the reason why dilute hydrobromic acid is of value in tinnitus. For this drug to act well the blood pressure must be above normal; the acid is given in doses of a drachm three times a day, reduces the blood pressure slowly and steadily, and gives relief in nearly every instance.

When the blood pressure in a case of tinnitus is normal or sub-normal, we can still use the same drug, qualified with other substances capable of slightly raising the blood pressure, such as digitalis and strychnine. That is to say, that if a patient has a low blood pressure, or a normal blood pressure, the hydrobromic acid will not effect any relief of the symptom, because it will still further lower the blood pressure, whereas when the blood pressure is high, the action of the drug alone suffices. Here a judiciously chosen endocrine will be of benefit—probably benefit of greater duration.

Unfortunately for me, and for those whom I have had to treat, endocrines came late on the field, so I cannot boast of very extensive knowledge of their employment.

Operations for the Relief of Tinnitus.

As I have already stated, my contention is that in future many fewer operations for the relief of tinnitus should be performed. I have myself destroyed the cochlea in five instances with one questionably good result. Other forms of operation have been advocated, and there has been a large proportion of fatalities. There is, practically speaking, not one proven cure.

Everybody who has dealt with tinnitus is aware that subjective noises are described by patients as noises in the ear, or noises in the head, and I think this differentiation is one of very considerable moment; especially is it of moment if the patient says that first they were in the ear, and now they are in the head, for what happens, no doubt, is this. A peripheral irritation causes a reflex irritability in the auditory centre, which is demonstrated by tinnitus. As long as the peripheral irritation, or any result of the peripheral irritation, remains, the tinnitus persists. If a catarrhal condition of the Eustachian tube occurs, which starts a tinnitus, that tinnitus will not cease if the catarrhal condition passes up into the middle ear, and causes any greater or lesser sub-inflammatory intratympanic condition, which, in its turn, may cause the formation or contraction of cicatricial bands. Hence, the necessity of early vigorous treatment to check a tinnitus in the early stages.

After tinnitus has been peripheral for a certain length of time, the outside duration of which I would myself place arbitrarily at three years, the subjective sound becomes central by what is termed catalysis; that is to say, a prolonged irritation of the central ganglion cells has caused the ganglion cells themselves to become diseased or disorganised. The tinnitus becomes central. I think that all one can do when this occurs is to try, if possible, by means of one's own will power or by careful medication, to enable the patients to tolerate and ignore as far as possible the annoyance to which they are subjected.

Pulsatory Tinnitus.

This is an interesting form of tinnitus; it is really the perception of the heart sounds as conveyed by the column of blood, and is always due to some form of obstruction to the clear outflow of sound, as opposed to the intake of sound. That is to say, that normally this sound, which is always present, is not perceived by the auditory nerve, because it has so free a power of passing through the tissues. The relief of this symptom, however, is not usually very difficult to obtain by the employment of digitalis, strophanthus, and hydrobromic acid.

The absence of any allusion to the employment of irrigation and rotation in the diagnosis of vertigo is, I am sure, likely to give rise to the belief that I have unintentionally omitted it. Such is not the case. I have nothing novel to add on this matter to the theories in modern text-books upon diseases of the ear. And I have carefully avoided discussing the effects of intracranial lesions and growths as going outside the province of this address.

LATE RICKETS AND OSTEOMALACIA IN DELHI.

AN ANALYSIS OF SEVENTY-THREE CASES.

By GRACE STAPLETON, M.D., B.S. Lond.,
WOMEN'S MEDICAL SERVICE, INDIA.

This series of cases was seen at the Lady Hardinge Hospital, Delhi, during the years 1921–24, chiefly in the medical wards and the out-patient department, but at the same time many similar cases were passing through the obstetric and other wards, where, however, there was not the same opportunity to take full notes. No selection was made of the patients, except to exclude those where there was any doubt in the diagnosis. Late rickets was diagnosed when there was a clear history that the patient had been quite well and free from all deformity of the legs or other bones until at least 8 years old, and marked enlargement of the lower ends of the radius and ulna about the epiphyseal junction was present, while on X ray examination, where it is possible to obtain it, signs of active disease with defective ossification and cupping of the end of the diaphysis were shown. The accompanying photographs (Figs. 1 and 2) of B., aged 12, and H., aged 17, show the clinical condition, and the X ray print (Fig. 3) of N. the radiographic appearances. It was only possible to examine a certain number of the patients by X rays, as there was no apparatus working in the hospital and they had to be sent for examination to a male doctor in the town, to which arrangement some of these purdah women objected.

Grouping of Cases.

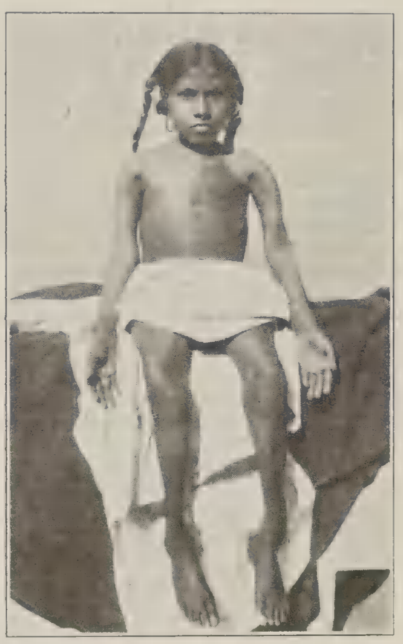
Osteomalacia was diagnosed when there were symptoms of pain in the lumbo-sacral region of the spine and thighs, often spreading to other parts of the body, difficulty in rising and walking, with the typical cautious, waddling gait, accompanied by tenderness in the bones.

Very soon after commencing the investigation one came to realise that they formed a fairly complete series, leading gradually from the typical late rickets case in young girls of 10, 12, and 14, through an intermediate stage in rather older patients in which the X ray signs of bony rickets were still present, but were accompanied by the deep-seated pains in the bones that are usually associated with osteomalacia, and then on to the well-developed forms of the latter disease that up to now has been thought to be mainly connected with pregnancy and lactation in young married women. The series, however, did not end here, but included women of 30 and 35, who were getting near to what in India is considered the later part of the child-bearing age, and terminated in two cases who had definitely passed the menopause, the elder of whom must have been at least 60, as she had been born a few years after the Mutiny.

Of the total cases 20 could be definitely diagnosed clinically as late rickets, as all showed enlarged wrist epiphyses, except a girl of 20 whose lesions had healed, together with some degree of beading of the ribs, though in nearly half it was only slight. Genu valgum or varum was present in 13 of the series. The wrist or the knee epiphyses of nearly half the cases were examined by X rays and the diagnosis confirmed. The age of these girls was from 10 to 20 years, and 16 of them were between 12 and 17.

Of the two who gave their age as 20, one, as stated above, showed the disease well past the active stage, but great deformities had been left, and the other was a case that dated back from early childhood with recrudescence at puberty and again following each pregnancy. On the whole the pain in these cases was not at all severe. They complained but little unless carefully questioned, and they had been brought for treatment owing to the difficulty in walking from the deformities more than for the actual pain.

Fig. 1.



B., aged 12, Mussulman. Late rickets of four years' duration. X ray examination showed multiple spontaneous fractures of the right forearm.

The next group of cases numbered six and consisted of girls of 16 to 20 in whom the symptoms were more like those of osteomalacia—i.e., more marked bone pains in the lumbo-sacral region of the spine, the hips, spreading all down the legs, and also felt in the ribs, and to a less extent in the arms. The pain was by no means restricted to the ends of the bones. Accompanying it there was muscular weakness and a very real difficulty in walking. Genu varum or valgum was present in half the cases, beading of the ribs in four, and enlargement of the wrist epiphyses in three. In those patients of whom it was possible to get an X ray plate, changes in the ends of the long bones were found similar to those in the preceding group. The cases of true clinical osteomalacia into which the previous group gradually merged numbered 47, and the age-limit was again higher. Most of the patients were in the early twenties, only nine being 16 to 20 and six were 30 or over. The symptoms showed little variation between case and case and were typical of the disease. In certain of the younger patients signs suggestive of late rickets were still present. Five had prominent wrists, and these were all under 20, two of the same age showed very definite beading of the ribs, and in nine others the costochondral junctions were abnormally easily felt, these patients being from 17 to 22 years old. Eight showed bowed legs. The youngest patient might have been included in the previous group except that her history and symptoms were typical of osteomalacia. X ray examination of her enlarged wrists showed a condition which could not be distinguished from late rickets.

Place of Origin of the Disease.

The results of grouping the patients according to the districts from which they came were as follows :—

Delhi.—Lived from birth ..	24	Ghaziabad and neighbourhood	4
Village life in childhood	23	Rohtak and neighbourhood	2
And Simla, half the year in each ..	2	Meerut district	2
And Agra	1	Bulandshahr district ..	2
Neighbourhood ..	2	Secunderabad district ..	2

Also one each from the districts of Saharanpur, Bareilly, Muzaffarnagar, Aligarh, Shahdara, Barot, and Hardwar. In two no note had been made where the disease began.

From this it can be seen that the disease is very prevalent among girls who are used to unrestricted village life in childhood, and then, generally soon after marriage, are brought into the crowded quarters of the town. On the other hand, village life does not exclude the possibility of late rickets or osteomalacia developing if certain other conditions are present, as shown below.

Caste of Patients.

The patients were of the following religions :—

Hindu..	55	Indian Christian ..	2
Mohammedan ..	15	Out-caste (sweeper) ..	1

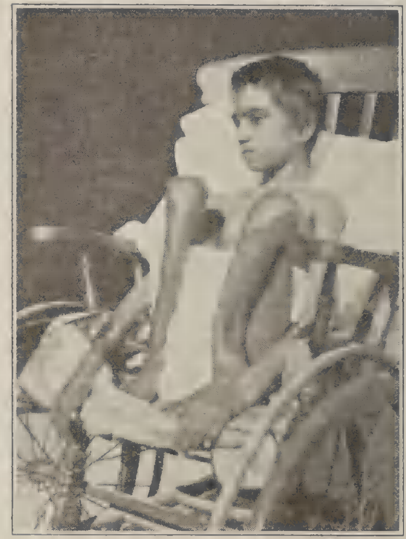
The Hindus were further divided into castes as shown below :—

Banya	34	Thakur	2
Kahar	5	Kayasht	2
Brahmin	3	Sais	2
Jaini	2		

Also one each of Kathri, Sonar, Bhisti, Khyat, and caste unknown.

From this it may be seen that the great predominance in Delhi among the Banya women, and of these especially the Agarwala Banyas are affected. Many of these are well to do. Among the Mohammedans, on the other hand, the disease occurs more among the poor, as only three of the 15 cases could be described as moderately well off, and at least four of the remainder said that they were in extremely poor circumstances.

Fig. 2.



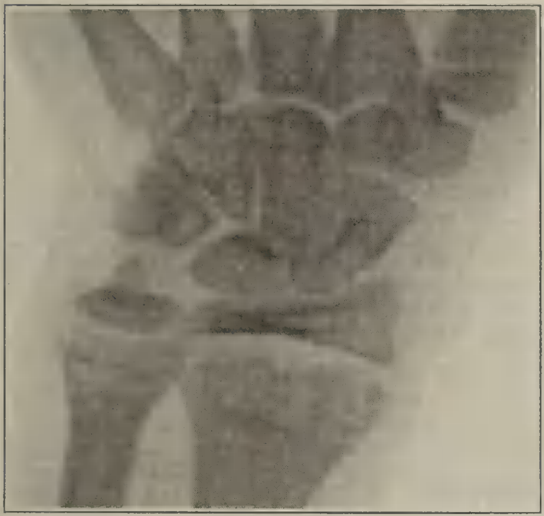
H., aged 17, Brahmin. Late rickets of eight years' duration. Unable to walk for one year. Spontaneous fracture of each ulna.

Diet.

Of the total patients 51 were strict vegetarians, and their diet consisted of chapattie—i.e., bread in the form of pancakes made of coarse wheaten flour and water, with dal (pulse) and vegetables. Those in moderately good circumstances took milk and fruit too, and the richer the patient the more ghi (clarified butter) would she use in the cooking of her food. The really well-to-do also had sweets made of sugar, curd, ghi, nuts, and flour. The ghi used is subjected to considerable heat in its preparation.

The non-vegetarian diet of the poorer patients was very like that of the vegetarian patient of similar standing, except for the occasional addition of meat, generally goat, perhaps once a week. The better class ones took meat often twice a day. The cases were grouped as follows :—

FIG. 3.



Radiogram of wrist of N., aged 16, Mussulman, showing the characteristic rickety changes at the end of the diaphysis of the radius and ulna. Symptoms of six months' duration only.

—	Diet.				Total.
	Good.	Medium.	Poor.	Very poor.	
Vegetarian ..	18	25	8	—	51
Non-vegetarian	2	5	9	6	22

From this it can be concluded that the better vegetarian diet containing animal fat in considerable quantity is not sufficient in itself to prevent the disease from developing.

Home Conditions.

Some attempt was made to estimate the home conditions as regards sunlight, airiness, and overcrowding, but one soon realised that this could not be done with any precision without seeing the actual buildings. In a tropical country a poor person is often better off as regards fresh air than a well-to-do one, as the rough hut made of unbaked bricks and mud is only one-storied and the sunlight may easily enter the courtyard, even in the town. The better-class Hindu house in Delhi, on the other hand, is generally built with the purpose of excluding sunlight and providing privacy. It is two or three stories high and the rooms all open into the central courtyard. There are as few windows as possible in the outside walls. If the house is high, the women who live on the ground floor may have very little, if any, direct sunlight, the rooms are often dark, and the air may be fairly stagnant. The houses of the better class Mohammedans, on the other hand, are often built in a different style, and the rooms are more open and airy, and there is more courtyard space. This may partly account for the different incidence of the disease among the two communities. The poor Mohammedan, who keeps strict purdah, lives often in the worst hygienic surroundings of all, as even her courtyard, if the house possesses one, may be too public to use. As regards overcrowding, one found that the circumstances of the family did not by any means correspond to the accommodation available. For instance, one woman, whose husband was a clerk drawing good wages, stated that her family consisting of eight persons lived in two small rooms, and there was only a tiny verandah and kitchen besides, and another quite well-to-do patient from the same town shared a single room with three other persons. One of the poorer Mohammedan women, who spent her time weaving and spinning, described her home thus : "Small, one-roomed. No windows. Verandah small. No sun ever enters. Used by three adults and one child." She lived there day and night and only slept on the verandah in the summer.

Several of the other women said they had lived under very similar conditions. Another patient's history was difficult to understand at first, as she stated that she came from a village and had to take a certain amount of exercise to fetch her water every day, and they were not particularly poor; but two years later one had an opportunity of visiting the house and seeing the appallingly dark room which she had not left for months, and where she had spent the greater part of each day before the disease had entirely crippled her. As other cases might be as misleading as this one, it would be useless to do more towards classifying them according to their home conditions.

Relation to the Purdah Life.

Every patient was carefully questioned about her home life and customs in connexion with the observance of purdah, and the following striking results were compiled from their answers :—

	Cases.	
Strict purdah always observed	11	
,, ,, not acknowledged, but contrary to custom to go out	8	
Never allowed out much in childhood and strict since marriage	13	
Allowed to play out of doors as a child, but kept in after marriage	15	
Unrestricted childhood, but after marriage allowed out very little	12	
Used to factory work, but discontinued some months before onset of illness and became purdah	2	
Not strict purdah, but prevented by illness from going out for many months before symptoms started	2	= 63
Not purdah, and used to a little out-door exercise	6	
Used to regular exercise	4	

In 86 per cent. of the cases, therefore, the disease was closely associated with purdah life.

Further inquiries were made into the last four cases. One was a beggar child of 10, whose history was not very reliable, and she had no relations to confirm her statements. Another was a girl of 16 of a well-to-do Banya family, who had begun to suffer from pains about her knees and wrists at the age of 10 or 11, but she continued to attend a day school in Delhi for the next two years until the increasing pain and difficulty in walking were severe enough to keep her at home. The third case was a Mohammedan of 22, whose family were too poor to observe purdah. She used to take a daily walk to visit a relative, who lived near some public gardens not far away, and she also went shopping in the bazaar, as long as her disease was not too advanced. As she lived in one small sunless room, she used also to go and sit in the sunlight in the lane outside.

The last patient was one who had certainly taken abundant exercise daily for many years. It was the only case of osteomalacia seen in a sweeper. She was married and went to live at her husband's house when only 7, and as they were poor began her work, that of removing refuse from Indian houses, at an early age. She worked for long hours, often amidst bad surroundings, and only gave up her daily work because of the disease, which started in connexion with her third pregnancy at the age of about 22.

Agé of Onset of Symptoms.

The following figures were obtained :—

Age.	Late rickets.	Osteo. and int.†	Age.	Late rickets.	Osteo. and int.†	Age.	Late rickets.	Osteo. and int.†
8–10	5	—	16	—	9	25	—	2
10	—	1	17	—	4	27	—	2
11	1	1	18	—	5	29	—	1
12	1	—	19	—	6	30	—	1
13	6	2	20	—	4	44	—	1
14	1	5	21	—	3	60	—	1
E.C.R.14*	1	—	22	—	1			
15	5	3	23	—	1	Total	20	53

* E.C.R.14 = Early childhood and recrudescence at 14.
† Osteo. and int. = Osteomalacia and intermediate cases.

Both diseases are therefore associated with the years of rapid growth of the body in the majority of cases. The last two cases were interesting in that they were typical in spite of their age. The old woman of over 60 had given birth to ten full-term children in her early married life with no difficulty, and had always had good health until she went on the pilgrimage to Mecca three years before. There she fell off her camel and injured her head, and was unable to walk for four or five months owing to pains in her limbs and back. Then she made a good recovery, returned to India, and kept well for two years, after which the osteomalacia symptoms gradually set in. On examination one found a triradiate pelvis of such a shape that it would be impossible for a full time child to pass. As she had spent all her money on the pilgrimage, she had lived in a very poor way in one dark, damp, ground-floor room ever since. The other woman had been used to taking a considerable amount of exercise in her younger days, as she frequently went to bathe in the river outside the city, but this had been gradually discontinued owing to increasing ill-health during the last eight years, and since a third attack of pneumonia the year before the disease had come on. She was a very severe case, completely bed-ridden, with much deformity of the chest, and tenderness in all the bones.

Relation to Menstruation, Pregnancy, and Lactation.

The onset was next considered in its relation to menstruation, with the following results :—

Before puberty	16
Relation to puberty not noted but occurred at ages 12–15	5
With or after puberty	50
After the menopause	2
Total	73

The disease therefore can occur both before and after the time during which the ovaries are functioning actively. The old method of treatment by removal of these organs could not on this account be always justified. The onset was then investigated in regard to its connexion with pregnancy, and the following facts were found :—

Onset—	Cases.
Before first pregnancy in	30
During ,, ,, ,, ...	14
,, successive pregnancy in	10
After delivery, in at least two of which patient was not lactating	4
During lactation	12
After weaning 3 year old child	1
Many years after last pregnancy	2

Among the 30 cases which developed the illness before any pregnancy had occurred all the 20 patients who had been included in the subdivision of late rickets on clinical grounds were found to be included, but apart from them there were the ten other cases. Osteomalacia in India is not only a disease connected with pregnancy. Neither is it one that occurs as the result of exhaustion from numerous conceptions, as the 14 cases occurring in the first pregnancy show when compared with the ten arising during the later pregnancies. Of these ten, three each occurred with the second and third pregnancies respectively, and only one with the fourth, two with the fifth, and one with the sixth.

Investigation made to determine as far as possible the time in the pregnancy when the symptoms commenced gave the following results :—

During 1st month ..	nil	During 7th month	4
,, 2nd ,, ..	,,	,, 8th ,, ...	1
,, 3rd ,, ..	2	,, last half of pregnancy	1
,, 4th ,, ..	4	Not noted	4
,, 5th ,, ..	4		
,, 6th ,, ..	4	Total	24

Of the 12 patients whose symptoms came on during lactation eight stated that they began to feel the pains within the first three months, and in a similar number it was the first child that they were nursing. It would again be difficult therefore to explain these cases on the grounds of physical exhaustion.

Onset in Relation to other Diseases or Injury.

In the majority of cases the disease was found to have come on insidiously with increasing bone pains and difficulty in locomotion, but ten patients gave a definite history of fever of various sorts having proceeded the osteomalacia symptoms, and in six others the symptoms followed an injury. Five patients stated that the disease had become much worse since an attack of fever.

Special Symptoms and Signs.

The history in most of the cases, especially the older patients, was very similar—i.e., deep-seated pains in the hips and lumbo-sacral region—spreading later to the ribs and sometimes widely over the body, always worse on movement, steadily increasing difficulty in rising and walking, often weakness and trembling in the legs, and in the end the patient becoming entirely bedridden, sometimes unable even to lift a water pot to give herself drink. Two special symptoms, however, were striking because of their frequency, one the occurrence of tetany, and the other that of spontaneous fractures. In no less than 30 out of 63 cases in which a record was made a history was given of definite tetany or attacks of cramps in the hands and sometimes the feet too.

Out of 29 cases in which it was possible to obtain an X ray photograph of the forearms or knees, signs of spontaneous fracture were found in 14. In many cases the patient was unaware that these had occurred, and had continued using their limbs so long as there was no accident to cause displacement of the fragments. One or two, however, were able to point to a small, slightly tender mass of callus along the posterior border of the ulna or elsewhere, and two were brought to hospital with malunited fractures of the lower end of the femur. One patient sustained a spontaneous fracture of the mandible while under treatment. Pelvic deformities, often of a very severe type, were found in a large number of cases, but the younger patients were not all submitted to systematic internal examination. Bending of the clavicles was noted in a few cases, and two adult patients showed very marked deformities of the thorax similar to those met with in infantile rickets.

Family History of the Disease.

In 20 out of 56 cases in which a note was made, the history was obtained of a similar disease having occurred among relations or neighbours. Seven patients had had a sister with similar symptoms, and the mother of another was said to have become very bent since the birth of this girl. Four related that another woman of a different family but living in the same house was affected.

Conclusions.

1. There is no sharp dividing line clinically between late rickets and osteomalacia cases, but intermediate cases are found showing characteristics of both. The difference in symptoms appears to be due to conditions of the tissues depending on the age of the patient.

2. The determining cause in the majority of cases is the lack of sunlight and exercise associated with the purdah life in North India.

3. The disease usually commences about puberty or in early adult life, but cases do occur occasionally in older women even past the menopause.

4. Osteomalacia is not uncommon in young women apart from pregnancy.

5. Tetany frequently occurs in the course of osteomalacia, and this suggests some close relationship between the metabolic disturbances that give rise to the two sets of symptoms.

These conclusions are in close agreement with those found in a previous paper[1] in which only the early cases of the series were used combined with others from Nasik.

The above investigation was carried out at the suggestion of the late Dr. H. S. Hutchison, of Glasgow.

COLLOIDAL KAOLIN.

I.

SOME PROPERTIES OF COLLOIDAL KAOLIN.

BY SIR WM. J. POPE, K.B.E., F.R.S.,

AND

R. T. M. HAINES, M.A.

ALTHOUGH china clay, or kaolin, is not acted upon chemically by physiological fluids, it is often used medicinally for internal administration. The ordinary kaolin of commerce is a powder of no extraordinary degree of fineness, but, since its medicinal applications depend upon an absorptive power which would be expected to increase with increased subdivision of the particles, it seems desirable that only the most finely divided kaolin should be used medicinally.

During the last few years methods have been devised for the separation of the larger or more gritty particles from kaolin and for the manufacture of a product consisting only of the more minute particles; the kaolin thus obtained is so finely divided that it shows colloidal properties when suspended in water. In view of the medicinal applications of this so-called colloidal kaolin it seems desirable to record its behaviour towards a number of reagents. The results now described were obtained with colloidal kaolin supplied by British Colloids, Ltd.; the material contained no agar and was the same as that used by Prof. Eyre. (See following note.)

A suspension of 1 g. of the colloidal kaolin in 100 c.cm. of water showed very numerous particles in vigorous Brownian movement on ultra-microscopic examination; for counting purposes a suspension containing 1 g. in 100 litres of water was used. The volume in which the count was made was—

$$27\mu \times 54\mu \times 1{\cdot}3\mu = 1{\cdot}9 \times 10^{-9} \text{ c.cm.};$$

this volume was found to contain 1·83 particles as the average of 52 counts. The suspension therefore contained $0{\cdot}94 \times 10^{9}$ particles per c.cm.; since 1 c.cm. contains 1×10^{-5} g. of kaolin, the average mass of the kaolin particles is $1{\cdot}1 \times 10^{-14}$ g., and 1 g. of the kaolin contains $0{\cdot}9 \times 10^{14}$ particles. These data concerning the size of the kaolin particles are, of course, not very accurate, but they show the order of the dimensions involved.

When shaken with water the kaolin remains in suspension for more than a week. The addition of 0·3 per cent. by volume of strong hydrochloric acid to the 1 per cent. suspension causes immediate flocculation, and the addition of 1·3 per cent. by weight of dissolved sodium chloride brings about complete precipitation within ten minutes. The colloidal suspension is not flocculated by the addition of moderate amounts of sodium hydroxide.

Kaolin a Negative Colloid.

The addition of the solid colloidal kaolin to negative colloidal solutions, such as those of arsenic trisulphide, antimony trisulphide, and the sensitive red colloidal gold, causes no change. When the kaolin is added to solutions of positive colloids, flocculation takes place immediately; thus, on adding the kaolin to colloidal ferric hydroxide solutions made (*a*) by dialysis of ferric chloride solution, (*b*) by steaming ferric formate solutions, or (*c*) by heating and dialysing ferric formate solution, the kaolin settles out, carrying with it the ferric hydroxide and leaving the supernatant liquor clear and colourless. These three colloidal ferric hydroxide solutions are the positive ones, A, B, and C previously described.[2] The flocculating effect upon these solutions shows the kaolin to be a negative colloid. Using a dialysed ferric chloride solution containing one part of iron in 2000 of solution, the smallest amount of colloidal kaolin which brought down all the ferric hydroxide was found to be 4·5 per cent. by weight of the solution itself; the original colloidal ferric hydroxide solution is acid to the extent of 0·0028 normal and the negative charge on the colloidal kaolin can be calculated in terms of caustic soda. The above results show that the kaolin corresponds to 0·25 per cent. of its weight of sodium hydroxide.

The adsorption of iodine from its aqueous solutions containing potassium iodide was also studied. On shaking a solution containing 1·45 g. of free iodine per litre with one-tenth its weight of kaolin and allowing to settle, 5 per cent. of the iodine is carried down by the kaolin; the concentration of iodine in the kaolin is thus about one-half of that in the supernatant solution.

Reaction with Dye-stuffs.

Basic dye-stuffs are removed from aqueous solutions by addition of colloidal kaolin. A stock solution containing 0·2 per cent. of night blue with a trace of hydrochloric acid was shaken up with the kaolin and allowed to stand, when deposition was complete in 12 hours; the addition of 5 per cent. by weight of kaolin removed 47 per cent. of the dye from the solution, and 10 per cent. of kaolin carried down 61 per cent. It will be noted that the concentration of the dye in the separating kaolin is many times greater than that in the residual solution.

Acid dye-stuffs are not adsorbed from aqueous solution by colloidal kaolin. Thus, kaolin does not settle from a 0·2 per cent. solution of erythrosine containing a trace of sodium hydroxide until an electrolyte, such as a minute quantity of solid calcium chloride, is added; the precipitated kaolin is quite white and tintometer comparisons show that no dye-stuff has been removed from the solution.

Amphoteric dye-stuffs behave differently towards colloidal kaolin in acid and alkaline solutions. Thus, a 0·01 per cent. solution of methyl-orange was divided into two parts, the one (*a*) being rendered faintly acid with hydrochloric acid, and the other (*b*) just made alkaline by addition of sodium hydroxide; 100 c.cm. of each was shaken up with 5 g. of colloidal kaolin. Solution (*a*) settled rapidly and the kaolin carried down with itself 68 per cent. of the dye-stuff originally present in the solution; it is noteworthy that the separated kaolin was coloured yellow or buff and not pink. Solution (*b*) did not settle until calcium chloride was added and the separated kaolin was quite white, no dyestuff being adsorbed.

It has now been shown that positive colloids are completely flocculated by colloidal kaolin whilst basic dye-stuffs are not completely removed from solution by the kaolin, but become distributed between the solution and the kaolin in proportions which can be determined.

This distinction is interesting in view of the results obtained by R. R. Walker in connexion with the action of kaolin on the cholera vibrio and on the toxin prepared from the bacilli; although it would appear that this worker used ordinary china clay which was not specially freed from the coarser particles his samples doubtless contained a large proportion of colloidal kaolin. Walker found that kaolin did not remove the vibrios from the suspension, although many were doubtless entangled in the depositing powder ; he found, however, that the cholera toxin is entirely removed by the kaolin. The toxin, in fact, behaves just like the positive colloids referred to above and not like a basic dye-stuff ; it therefore seems indicated that the toxin is a positive colloid.

II.

THE ABSORPTION OF TOXIN BY KAOLIN.

By JOHN W. H. EYRE, M.S. Durh., F.R.S. Edin.,
PROFESSOR OF BACTERIOLOGY, UNIVERSITY OF LONDON.
(*From the Bacteriological Department, Guy's Hospital.*)

In 1921 Walker undertook some experimental observations (to which Sir William Pope refers in the preceding note) upon the absorptive properties of kaolin, the results of which explained in part its value when administered to cases of Asiatic cholera by Kulme at Nish, and Braafladt and himself in China.[1]

This work, together with the gradually accumulating mass of clinical evidence, has been followed by the exhibition of kaolin in cases of acute and chronic colitis in temperate zones ; it has also stimulated manufacturers to prepare "medicinal kaolin" in a really fine state of division, and better still—in the colloidal form, and in some quarters, prompted no doubt by an appreciation of the action of agar when introduced into the atonic alimentary tract—to endeavour to enhance its value by the addition of agar-agar. When considering such a combination, however, one is struck by the possibility that the addition of agar—itself absorbent, though inferior to kaolin in this respect—might hinder rather than help the action of the kaolin. This possibility is strengthened by the results of a few experiments planned to demonstrate any possible difference in the absorbent power of colloidal kaolin (K) and colloidal kaolin plus agar (KA), both of which were supplied for this purpose from the Crookes's Laboratories.

A. *Absorption of Diphtheria Toxin.*

A quantity of a commercial diphtheria toxin was obtained and its lethal unit approximately determined by the administration of varying quantities to a number of young adult guinea-pigs of a uniform weight of 250 g.

Series I.

0·1 c.cm. = } Death (in 15 hours).
0·0025 ,, = }
0·0016 ,, = ,, (,, 48 ,,).
0·0013 ,, = Unaffected.

The result thus obtained was controlled by a second series of determinations.

Series II.

0·005 c.cm. = } Death (in 23 hours).
0·0025 ,, = }
0·002 ,, = } ,, (in 40 hours).
0·0016 ,, = }
0·0013 ,, = Unaffected.

On the basis of these observations each cubic centimetre of the toxin was assumed to contain at least 600 lethal doses.

Kaolin-agar to the extent of 10 per cent. was now added to a portion of the diphtheria toxin and the mixture shaken vigorously for some minutes, then filtered through Swedish filter paper and the filtrate employed in the injection of a further series of standard guinea-pigs, thus :—

Series III.

0·2 c.cm. = 120 m.l.d. } Death (in 18 hours).
0·1 ,, = 60 ,, }
0·01 ,, = 6 ,, ,, (,, 24 ,,).

Kaolin to the extent of 10 per cent. was now added to another portion of the diphtheria toxin and the mixture similarly treated, with the following results :—

Series IV.

0·2 c.cm. = 120 m.l.d. } Death (in 18 hours).
0·1 ,, = 60 ,, }
0·01 ,, = 6 ,, ,, (,, 48 ,,).

Under the conditions of these experiments no obvious difference between the kaolin plus agar and the kaolin could be demonstrated, as each preparation failed to adsorb any appreciable amount of toxin—indeed, if any adsorption took place, it was to a very slight extent, since the reduction in toxicity (if any) was less than the equivalent of six minimal lethal doses.

The experiment was then varied in the following manner : Diphtheria toxin was filtered through a layer of kaolin plus agar about 1 cm. in thickness. This was prepared by making a thick paste of kaolin plus agar with sterile water, smearing it on a perforated disc which was placed on a sterile funnel fitted to a filter flask, which was then thoroughly exhausted to remove excess of moisture from the kaolin bed.

Series V.

2·0 c.cm. = Death (in 21 hours).
1·0 ,, = ,, (,, 20 ,,).
0·1 ,, = ,, (,, 40 ,,).

Diphtheria toxin similarly filtered through a layer of kaolin gave the following results :—

Series VI.

2·0 c.cm. = Death (in 80 hours).
1·0 ,, = ,, (,, 120 ,,).
0·1 ,, = Unaffected.

These two groups of inoculations bring into evidence striking difference in the adsorptive action of the two preparations. Kaolin plus agar possesses very slight action and is unable to reduce the toxicity even to the extent of six minimal lethal doses, whilst the native kaolin apparently adsorbs about 5 m. lethal doses.

The above experiments illustrate the action of kaolin preparations upon one type of bacterial poison—viz., the extracellular or soluble toxin. The majority of the pathogenic bacteria concerned in intestinal infections resulting in toxæmia depend, however, for their toxic properties on metabolic products stored within the protoplasm of the organisms and only liberated when the bacterial cell undergoes disintegration. To study the action of kaolin on this type of poison a member of the typhoid-dysentery group was selected.

B. *Action on Toxin of B. dysenteriæ.*

B. dysenteriæ (Shiga) when grown in peptone broth for some 48 hours at 37° C. and then killed by heating to 60° C. for one hour yields a fluid which, if injected intravenously into rabbits, causes a fatal toxæmia. In animals killed by this method death is preceded by diarrhœa, and the subsequent post-mortem examination shows : (1) A considerable quantity or excess of peritoneal fluid ; (2) distension of intestinal blood-vessels and hæmorrhages ; (3) considerable injection of the mesentery and omentum ; (4) enlargement of the mesenteric glands ; and (5) fluid blood in the heart.

Rabbits vary slightly in their susceptibility to Shiga's bacillus ; therefore the toxicity of a killed culture of this organism, prepared as above indicated, was tested on two series of 1200 to 1500 g. rabbits.

Series VII.

Rabbit, 4·0 c.cm. = Death (in 48 hours) }
2·0 ,, = ,, (,, 8 days) } Typical P.M.
1·0 ,, = ,, (,, 7 ,,) }
0·1 ,, = Unaffected.

Series VIII.

Rabbit, 5·0 c.cm. = Death (in 24 hours) }
2·0 ,, = }
1·0 ,, = } ,, (,, 3 days) } Typical P.M.
0·1 ,, = ,, (,, 12 ,,) }

The inference to be drawn from the results of Series VII. and VIII. is that the toxicity of the killed culture in terms of minimal lethal doses is approximately two per cubic centimetre.

One portion of the killed culture of *B. dysenteriæ* was next filtered through a layer of kaolin plus agar, exactly as was done in the case of the diphtheria toxin. Next the filtrate was concentrated to one-third its bulk by evaporation at 37° C., when theoretically, 1 c.cm. should have contained five or six minimal lethal doses. This concentrated filtrate was used to inject 1500 g. rabbits as follows :—

Series IX.

10·0 c.cm. = 50 m.l.d. Death (in 19 hours).
5·0 ,, = 25 ,, Unaffected.

---

[1] The Lancet, 1921, ii., 273.

Another portion of the killed culture was filtered through a similar layer of kaolin and then concentrated to one-third its bulk in the same manner. The injection of this concentrated filtrate produced the following results :—

Series X.

10·0 c.cm. = 50 m.l.d. Death (in 24 hours).
5·0 ,, = 25 ,, Unaffected.

In these experiments no very obvious difference between the pure kaolin and that admixed with agar can be shown, for the difference in the time (five hours) that elapsed between inoculation and death in the two rabbits receiving approximately 50 m.l.d. is too small for consideration.

LOCAL INSULIN REACTIONS.

BY R. D. LAWRENCE, M.D. ABERD.,*
CHEMICAL PATHOLOGIST, KING'S COLLEGE HOSPITAL.

BESIDES its general action on blood-sugar and carbohydrate metabolism, insulin causes definite local effects and reactions at the site of injection. These reactions vary with the individual, the site of injection, and the brand and batch of insulin used. The variations are not generally recognised and have been the cause of much worry to patients and to physicians who have had, perhaps, only a few insulin cases to treat. They have been the cause also of many complaints to the manufacturers about their insulin, and in some cases have led doctors to abandon the treatment, even where it seemed essential. It may accordingly be useful to summarise the most common reactions and to point out the circumstances in which they are most likely to occur and the way in which they may be minimised. A few detailed examples will be given of the effects of changes of insulin in a few specially sensitive individuals.

Immediate and Delayed Local Reactions.

The local reactions may be conveniently divided into *immediate* and *delayed*. In all cases it is the hypodermic injection of insulin that is described and not the intradermic or intramuscular. Injections into the skin itself meet with great resistance, cause an obvious pigskin appearance, and much local irritation, swelling, and pain. They should always be avoided and should be suspected as the cause of the trouble when patients who are beginning to administer their own insulin complain of much difficulty and pain. Intramuscular injection gives rise to no obvious swelling but to a deep-seated pain which lasts from 12 to 36 hours. The following local reactions are those which may occur when a hypodermic injection is skilfully carried out. All my patients keep their syringes in methylated spirit or absolute alcohol in a glass test-tube or metal case, and never sterilise them by boiling or strong antiseptics. In this way trouble is minimised, and not a single abscess or infection of any kind has occurred in patients of all classes and conditions. I have only one or two patients who do not administer their own insulin. These observations have been made with the British insulin of Messrs. Allen and Hanburys (A.B.) and of Burroughs and Wellcome (B. W.) and American Lilly insulin, and to a less extent with Messrs. Boot's insulin.

The *immediate local effect* of an injection of insulin is *stinging* at the site of injection. This is most marked during the first few days of treatment and is rarely troublesome after ten days. It is due to the slight acidity of the insulin solution and, if the patient finds the stinging very irksome, it can be largely removed by neutralising the acidity by sodium bicarb. as suggested by Dr. G. R. Stilwell.[1] I have never had occasion to use it. The tissues seem to acquire a local tolerance to insulin and stinging is likely to recur when the injections are changed to a new part of the body. They also recur quite frequently when a change is made to a different make or even a different batch of the same insulin. This often makes patients conclude that a particular batch of insulin does not suit them, while if they persisted with it the increased stinging usually disappears after one or two injections. Local *urticarial wheals* occasionally appear immediately on injection and often when the injection is partly intradermic. As might be expected, these occur most frequently in individuals sensitive to proteins. In certain cases it seems to be a slight anaphylactic reaction which occurs when a return is made to a brand of insulin which has not been used for some time.

Delayed local reactions are much more troublesome. They closely resemble vaccine reactions, and like the latter are more liable to occur in the obese. Thus they occur more frequently in women than in men. I have never seen them in a really emaciated case. They have occurred in about 30 per cent. of my cases. In such cases during the first day or two of the injections only the usual stinging results. About the third to the fifth day hot brawny swellings begin to appear at the site of injection, develop fully in 6 to 12 hours, and have usually disappeared again in 24 to 36 hours. They may cause much pain and irritation, and can be partly alleviated by cooling lotions. I have seen general pyrexia of 100° F. develop for a few days in one severe case. Usually these reactions begin to grow less after seven to ten days and disappear altogether after two or three weeks. Occasionally they persist much longer, but I have never seen them cause serious trouble for more than three months. Sometimes a change from one make of insulin to another makes them reappear for a week or two. Some patients seem to be much more liable to these delayed reactions if the injections are given in the arms instead of the abdomen and thighs. This type of reaction is probably due to the protein content of the insulin and great variations might be expected depending on the sensitivity of the individual. But I can offer no explanation of why they should occur in one part of the body and not in another.

Anaphylactic Reactions.

General anaphylactic reactions have been reported in a few cases by Wilder and Boothby[2] and by Williams[3] in America. So far they do not seem to have been recorded in this country. These reactions were characterised by the typical symptoms of urticaria, vomiting, collapse, &c., and occurred almost immediately after the injections. Wilder's cases were reported in the early days of insulin when it contained far more protein than it does now. And Williams's case suffered from anaphylaxis only when insulin made from pig pancreas was used (Lilly insulin), and not from beef pancreas. Many more individuals are sensitive to pig than to beef protein, and the probable reason why anaphylaxis has not been observed in this country is that British insulin is made only from beef pancreas. I have found local urticarial reactions more liable to occur with Lilly than with British insulin.

Prevention of Subcutaneous Thickening.

Subcutaneous thickenings and great toughness of the skin ensue when injections are continued too long in any one part of the body. These should be prevented by changing the site of the injection from one arm or thigh to another or to the chest or abdomen every week or ten days. Some patients are apt to use one limited part of the body too long because it is very accessible and convenient. On the other hand, I do not think it is best to change the site of injection from the leg to the arm, &c., at every injection, because in this way local tolerance to the sting of the insulin is never fully developed. But, of course, no two punctures should be made at exactly the same spot within 24 to 48 hours.

It must not be thought that many cases have much local trouble with their injections. The majority administer their own insulin with perfect equanimity after the first fortnight and declare they feel no pain or discomfort. Occasionally, for no apparent reason, one injection causes more stinging, swelling, urticaria, or itching than usual. But usually it is found that there has been a change of the batch or brand of insulin which the patient had not noticed before being questioned. It may be useful to record briefly the typical vicissitudes of local reactions that have occurred in some of my closely observed pedigree patients.

---

Illustrative Cases.

A young male adult commenced Lilly insulin in May, 1923, with doses of 15 to 20 units. He experienced much local stinging and some swelling and delayed reactions for the first ten days, but these soon wore off. A month later he began to administer his own insulin in his thigh and the stinging and swelling recurred for a few days. He commenced British insulin (A.B.) in August and experienced no change in local reactions, although at that time Lilly insulin was stronger than British and he had to use much more of the latter. During September he used Lilly and A.B. insulin and noticed no difference in the local reactions. He used nothing but A.B. insulin until March, 1924, when he recommenced Lilly insulin, and for a few days had marked protein reactions, immediate urticarial wheals round the injection, and much local swelling, itching, and pain. He had obviously had time in the interval of six months to become sensitised to pig protein. When he changed to A.B. and B.W. insulin six months later, no protein reactions ensued. He is not sensitive to pig protein by mouth, and when he had an odd injection of Lilly insulin a few days ago it caused no protein reaction, probably because Lilly insulin, like all insulin, is now much freer from protein. He now uses both A.B. and B.W. insulin and nothing occurs locally except slight stinging, which occasionally becomes more marked when he changes the site of injection or uses a different batch of insulin.

An obese woman of 50 has had much trouble with delayed local reactions. These commenced on the fourth day of treatment when she was having two doses of 10 units. They became more severe and by the tenth day a hard, hot, brawny and painful swelling occurred at the site of every injection and were a great affliction. She felt general malaise and her temperature rose in the evening for two days to 100° F., for which no other cause than the insulin could be discovered. During this pyrexial period the insulin was partially ineffective and the dose had to be nearly doubled to obtain the same result. The reactions then began to decrease but were quite troublesome for another four months. Both A.B. and B.W. insulin caused these reactions, but after six months they had practically disappeared. When she changed her insulin from one batch of B.W. insulin to another (from batch 282 to 286) severe local reactions suddenly reappeared.

Another male patient, aged 62, commenced treatment with B.W. insulin and experienced severe stinging and delayed reactions which at once disappeared when he substituted A.B. insulin.

Variations in Quality of Insulin.

I do not think we can conclude in any way that one make of insulin is better than another, but that some brands and batches of insulin suit one patient better than another. Undoubtedly, pig insulin (Lilly) is more likely to cause protein reactions than ox insulin. It is no secret that great variations have occurred and probably do still occur to a less degree in the strength of different batches of insulin, and it would appear that qualitative changes whose effect can be observed on patients also occur. It is wrong to condemn a special make or batch of insulin because it seems to disagree with certain patients. Individual variations must be recognised and different preparations of insulin may have to be tried to suit exceptional cases. But we have every reason to be proud of and to congratulate the manufacturers on the high quality of the insulin produced in this country—and to be thankful for the low price.

Some Useful Points.

Every attempt should be made to make the daily injection of insulin as comfortable and easy as possible, and in this connexion the following points may be useful. It gives far the least trouble and is entirely satisfactory to keep the syringe and needle sterile in spirit in a metal case or glass test-tube. A non-irritant skin disinfectant must be found for every patient in whom variations to different antiseptics occur. The pain of the puncture can be minimised by the use of fine and sharp needles, by inserting the needle as nearly at right angles to the skin as possible, thus traversing as little skin as possible, as this is the painful part of the injection. Usually, by moving the point of the needle lightly over the skin it is easy to find a spot which is quite insensitive to the prick and where the injection can be made quite painlessly, because it avoids the nerve-endings for pain. The sting of the insulin is usually very slight and it can be made less by pinching somewhat vigorously the skin and underlying tissues into which it is being injected. The best sites for injection are the parts of the body where the skin is loosest and which are not subject to pressure or to much movement in the underlying muscles. The calves are unsuitable because the skin is very tight over them, and the best places for self-administration of insulin are the front and outer aspects of the thighs, the abdomen, and the lower part of the chest where both hands can be used in the injection. The forearms and outer sides of the upper arms are also available when someone other than the patient is giving the injection. By these means the initial repugnance that many patients feel to daily injections soon gives way to the indifference of an easy habit.

ACETYLENE, ETHYLENE, PROPYLENE.*

BY FRANCIS E. SHIPWAY, M.D. CAMB.,
SENIOR HON. ANÆSTHETIST, GUY'S HOSPITAL, AND LECTURER IN ANÆSTHETICS TO THE MEDICAL AND DENTAL SCHOOLS; SENIOR ANÆSTHETIST, ST. PETER'S HOSPITAL FOR STONE.

THERE are many unsaturated hydrocarbons, some of which have anæsthetic properties. Three of them, acetylene, ethylene, and propylene, have recently been the subjects of investigation, and as the reports of the first two, and the preliminary notice of the third, appear favourable to their anæsthetic value, it was decided to undertake an experimental and clinical inquiry into these gases. This work, with the coöperation of Prof. M. S. Pembrey, F.R.S., has been in progress at Guy's Hospital for some months. It may be said at once that whilst a favourable view has been taken of ethylene, acetylene, for reasons given below, was discarded after a short trial, and propylene has received as yet insufficient trial to warrant the drawing of definite conclusions.

The mode of action of these gases is not known. They are inert, non-toxic gases, carried in simple solution in the blood. If ethylene is passed through diluted dogs' blood the absorption bands of oxyhæmoglobin remain unaltered. They are rapidly absorbed and rapidly eliminated. It is supposed that, like nitrous oxide, they have a direct action on the cells of the central nervous system by interference with oxidation. It is of interest in this connexion to note that ethylene anæsthetises certain plants. The Chicago carnation-growers discovered in 1908 that the illuminating gas used in the houses, which contains 4 per cent. ethylene, caused the flowers to go to sleep, and prevented the buds already showing petals from opening. A concentration of 1 in 2,000,000 parts of air is sufficient to cause these flowers to close. The same concentration had a similar action on castor-oil plants and sweet peas. These facts show that anæsthesia is a more complicated process than an effect upon a specialised nervous system. How these gases interfere with metabolism is not known. An investigation to decide the question is being conducted by Prof. Pembrey.

Animal experiments having been carried out by us with these gases, they were then used on patients. A sight-feed apparatus was employed, and anæsthesia was conducted upon the lines of nitrous-oxide-oxygen anæsthesia, with partial rebreathing. In some cases soda-lime was used to absorb the CO_2. In all cases a preliminary injection of atropine was given. Details of the animal experiments will be published at a later date.

---

* This research has been carried out on behalf of the Joint Committee of the Medical Research Council and the Section of Anæsthetics of the Royal Society of Medicine.

I.—ACETYLENE.

The results of earlier workers[1][2][3] with acetylene were discouraging; experimental animals either died suddenly or after some hours if the concentration of acetylene was low, even though they had been removed from its atmosphere. Wieland,[4] during an investigation into the pharmacological properties of this gas, obtained similar results, and it was not until he experimented with pure acetylene that he was able to show that low concentrations are harmless even when administered for prolonged periods. He carried out an extensive research, and having demonstrated that the gas provides a safe and non-toxic anæsthesia, persuaded Gauss to give it a clinical trial. So satisfactory were the results that several thousand successful cases of anæsthesia have been reported by Gauss,[5] and later by Solbach,[6] Döderlein,[7] and others.

TABLE I.—ACETYLENE.

No.	Sex.	Age.	Condition.	Operation for—	Anæsthetic.	Injection atropine or morphine.	Time, in mins.	Proportion of gases.	Vom.	Nausea.	Remarks.
1	M	12	Good.	Undescended testis.	Acet.-oxy.	1/100 A.	25	75 : 25 60 : 40	4	0	½ hr. after anæs. still dazed, completely conscious in 1 hr.
2	F	6	,,	Tubs. cervical gland.	Gas-oxy. acet.-oxy.	1/100 A.	12	Do.	1	0	—
3	F	3	Toxic.	Exploration of hip-joint.	—	1/150 A.	45	60 : 40	0	0	Glycosuria before op., still present third day, absent fifth. Ethylene on previous occasion.
4	M	18	Good.	Hallux rigidus.	—	1/100 A.	43	60 : 40	1	0	—
5	M	24	Fat, nervous.	Rad. cure of ing. hernia.	—	1/6 M. 1/100 A.	23	60 : 40	0	Slight.	Urine normal after op.: 1/6 gr. M. during recov.
6	M	13	Good.	Undescended testis.	Acet.-oxy.	1/100 A.	37	50 : 50	0	0	Salivation at start. Urine normal after op.
7	F	38	Slight physique.	Hæmatoma of thigh.	Gas-oxy., acet.-oxy.	Do.	13	75 : 25	0	—	Nausea 12 hrs. Ethylene 14 days previously, nausea 12 hrs.
8	F	66	Stout.	Rad. cure of bilateral fem. hernia.	Acet.-oxy.	Do.	60	75 : 25	3	0	1/6 gr. M. before end of op.
9	F	19	Hysterical, good physique.	Ext. piles and sigmoidoscopy.	Gas-oxy. acet.-oxy.	Do.	32	75 : 25	4	Slight.	No anal or rectal reflex elicited.
10	M	25	Muscular.	Varicose veins.	Gas-oxy. acet.-oxy.	Do.	33	75 : 25	1	0	Slight salivation. Urine next day contained diacetic acid and substance which reduced Fehling's solution.
11	F	31	Good.	Amputation of 2 phalanges	—	Do.	23	75 : 25	1	—	Coughing after induction.
12	M	8	,,	Rad. cure of ing. hernia.	—	Do.	18	60 : 40	24 hrs.	—	Bronchial catarrh after op. for 48 hrs.
13	F	37	Toxic.	Pyosalpingectomy.	CE: acet.-oxy.	Do.	60	75 : 25 60 : 40	1	0	CE for 3 min. Salivation. Good relaxation 1/6 M. half way through op.
14	M	22	Good.	Rad. cure of fem. hernia.	Gas-oxy. acet.-oxy.	Do.	47	75 : 25	0	0	Salivation. Acute bronchitis following op. History of recent "cold."
15	M	21	Muscular.	Removal of lipomata of scalp.	—	Do.	15	Do.	0	0	—

Acet.-oxy. = Acetylene-oxygen. Op. = Operation.

Acetylene, C_2H_2, is lighter than air, and is very diffusible. It is soluble in water, 1 c.cm. of water dissolving 0·745 c.cm. at 37° C. at a pressure of one atmosphere. Blood under similar conditions dissolves slightly less—viz., 0·735 c.cm. Schoen and Sliwka[8] have shown that the percentage of acetylene absorbed by the blood is directly proportional to the partial pressure of the gas in the inspired air. In the first five minutes 88 per cent. saturation was found in the arterial blood of the rabbit, and saturation was complete in 17 minutes; elimination was complete in six minutes. In man, experiments with venous blood showed that 90 per cent. of the gas was eliminated in five minutes after withdrawal of the anæsthetic. Acetylene is non-toxic and highly inflammable. It forms explosive combinations with copper and silver. The dried and carefully purified gas, which is named narzylen in Germany, is put at a pressure of 15 atmospheres into steel cylinders filled with a porous material containing acetone, in which the gas readily dissolves. A 40-litre cylinder contains approximately 5 cb.m. acetylene. Impurities which have to be removed include chloride compounds and phosphoretted and sulphuretted hydrogen. The purified gas contains a very small amount of other CH compounds and some air. In order to remove acetone which comes over with the gas, special washing arrangements have to be provided. Another precaution against the escape of acetone is the provision of a meter which indicates the lowest working pressure—viz., 2–3 atmospheres. Acetone is unpleasant to inhale; pure acetylene is said to have no unpleasant odour. However this may be, it is customary to pass the gas through some substance (placed in the outlet valve) which has been saturated with a sweet-smelling oil. The gas which was obtained from Stockholm for the purposes of the Committee by the Gas Accumulator Co., and is stated to be purer than narzylen, possesses a distinctly disagreeable and somewhat pungent odour, and leaves a bitter taste in the mouth. Some of this objectionable odour is certainly due to inefficient removal of acetone.

Wieland found by animal experiment that a mixture of 45–55 per cent. acetylene with 55–45 per cent. oxygen anæsthetises white mice. The percentage varies very little with other animals. If the percentage is increased to 80 and upwards respiration becomes rapid, shallow, and irregular, and finally ceases; artificial respiration restores breathing. There is no action on the heart or vasomotor centre; death takes place from respiratory paralysis. For clinical use a mixture of 70–80 per cent. with 30–20 per cent. oxygen is used for induction, and is gradually replaced by 50 or 40 per cent. acetylene. Acetylene anæsthesia resembles nitrous-oxide, ethylene, and propylene anæsthesia in its mode of action, non-toxicity, rapidity of induction and elimination, and causation of death, but is superior to nitrous oxide and ethylene in depth of anæsthesia and in safety, for the percentage of oxygen is always higher than that contained in air. Unfortunately it is, like ethylene and propylene, inflammable, and the presence of a cautery or flame or electric spark in the immediate neighbourhood of the expired air is dangerous. Careful analyses [9] of the composition of the air of poorly ventilated operating theatres agree that the air contains a very small proportion of acetylene; near the patient's head the percentage was 0·8–1. Higher concentrations were never found. Von Sturm's figures agree with these. The explosion limits are 3·35–52·3 per cent. Hollemann places the lower limit at 3·82. Rimarski [10] states that the great diffusibility of acetylene and its slight concentration in the theatre account for the very large number of operations performed with the thermo-cautery without any disturbance. Döderlein was less fortunate.[11]

Induction with a 75 per cent. mixture of acetylene in oxygen takes place in about one minute without struggling or excitement, and without unpleasant sensations, except those of smell or taste; in order to overcome this objection gas-oxygen was administered in some cases for a few breaths, and acetylene then run into the bag with an increasing quantity of oxygen as the partial pressure of acetylene rose. Maintenance of anæsthesia for prolonged periods is easy, the percentage of acetylene being gradually reduced. The breathing is, as a rule, easy and quiet, but its character depends partly upon the type of patient and partly upon the method of administration —i.e., upon the extent of rebreathing. Rimarski [10] examined the composition of the expired air in 11 cases, and found that whilst the percentage of acetylene and oxygen in the samples analysed corresponded fairly accurately with the percentages registered by the Drager apparatus, the percentage of CO_2 never exceeded 1·7, the range being 0·5 to 1·7. With this apparatus the expired air escapes directly into the operating room. Solbach and Hazelhorst speak of the frequent occurrence of apnœa; this is certain to occur, owing to acapnia, if some rebreathing is not practised. The CO_2 content of the inspired air exerts a profound influence both upon the rate of breathing and the extent of peripheral vaso-dilatation, and therefore again upon the character of breathing by reason of congestion of the air-passages. Congestion leads to some degree of respiratory obstruction, and it is obvious that if the rate of breathing is raised, and the air-passages slightly obstructed, respiration will gradually become hampered and the tendency to obstruction increase, even in the presence of an excess of oxygen. This difficulty can be partly overcome by a lessening of the rebreathing factor; absorption of CO_2 by soda-lime completely removes it.

The presence of small quantities of acetone, which is irritating, produces in some cases swelling of the mucous membrane of the upper air-passages and salivation, and tends to embarrass breathing; no salivation occurred in our animal experiments. It is highly desirable to remove all traces of acetone, not only for this reason, but also because its odour is disagreeable to the patient if induction is carried out with acetylene. This removal, however, is difficult, as the gas, which is administered at about the rate of 3 litres per minute, carries over with it an appreciable amount of acetone. An elaborate washing apparatus was not considered desirable from the point of view of simplicity and convenience. The matter was therefore referred at my request by the Committee to Dr. H. King, of the National Institute for Medical Research. After many experiments Dr. King reported that "the only effective and economical system of washing would be the counter-current system, a tower filled with beads or Lessing rings of inert metal down which a thin stream of water is running, thus providing efficient washing surface for the upward current of acetylene." This method proved to be successful, "not a trace of acetone being found after passing 6 litres of acetylene in five minutes, the volume being about 300 c.cm. or equivalent to a column 8 in. high and 2 in. in diameter." This apparatus, besides being somewhat fragile, I found to be not wholly suitable for clinical use, for it requires the provision of a pipe or tube connected with a water supply for leading in water, and a second for removing it. The Drager apparatus used by Gauss contains a special washing apparatus, but there is some evidence to show that it is not entirely efficient. Goldman [12] has met with the same difficulty; he also states that acetylene loses some of its anæsthetic properties by the removal of acetone, which is known to be a weak anæsthetic.

The pulse in a normal case remains steady and full; if the partial pressure of CO_2 is high the rate slows and the blood pressure falls. Blood pressure usually falls slightly in a normal case. Muscle tone is much diminished, the eyelids being semi-relaxed and exposing the globes, which are fixed in the cadaveric position. Occasionally they roll slowly from side to side. The pupil is slightly dilated and reacts briskly to light. Conjunctival reflex is absent, corneal reflex present but dulled. Swallowing reflex is absent, cough reflex present. There was no reflex effect upon respiration during traction on the sac in Cases 5 and 8, nor during operation on Case 9 (Table I.). The amount of bleeding is slightly increased, but whether this is due to the action of acetylene or to the vaso-dilatation effect of CO_2 is not certain; judging from improved results obtained by absorption of CO_2 during ethylene anæsthesia I am inclined to think that acetylene is not the chief cause. Recovery is very rapid, consciousness being regained in 2–3 minutes. Acetylene could be smelt in the breath for some hours afterwards. Leake and Hertzmann[13] state that the pH of blood determined colorimetrically undergoes a slight fall.

It was tried in only one case of laparotomy—and then successfully—for I felt convinced that it would provide an inefficient anæsthesia in all but exceptional cases. It is possible that by cutting down the percentage of oxygen in the mixture a greater degree of muscular relaxation can be obtained, but this dangerous aid to anæsthesia is obviously undesirable. Care was taken on all occasions to administer not less than 20 per cent. oxygen, nor was it desirable to employ other adventitious aids to anæsthesia—e.g., ether and morphine and scopolamine—as this inquiry was undertaken with the sole object of ascertaining the merits and demerits of acetylene as an anæsthetic for surgical purposes. It is true that a preliminary injection of morphine was given to Case 5 (Table I.), but it was so given to allay undue nervousness, and the operation could well have been carried out with acetylene alone. Anæsthesia was in all cases completely satisfactory. But as the odour of acetylene, the removal of acetone, and the tendency to salivation seemed to present weighty objections to its continued use, the inquiry was abandoned, more especially as two other members of this group —viz., ethylene and propylene—appeared likely to afford more favourable results.

II.—ETHYLENE.

The history of the discovery of this anæsthetic is too well known to require narrating; a full account has been given by Brown,[14] and Luckhardt and Carter,[15] who first administered it to human beings. Possessing the formula C_2H_4, it has a specific gravity of 0·9784, boiling-point of −105° C., and melting-point of −169° C. It is sparingly soluble in water (0·149 c.cm. at 20° C.). It liquefies at 10° C. under a pressure of 60 atmospheres, and is pumped into cylinders at a pressure of about 1200 lb. Being an inflammable gas under pressure it is very sensitive to changes of temperature; the cylinders must not be stored near any source of artificial heat nor left in the sun. The relative explosion hazards of ethylene and ether when mixed with air or oxygen are practically equal. It is stated that metal tubing should be used for all connexions of the anæsthetic apparatus as there is danger of a static spark occurring due to the friction of the passage of the gas through rubber tubing. Luckhardt[16] quotes two cases of explosion which are said to have been due to this cause. A mixture of 4–15 per cent. ethylene in air forms an explosive mixture, and if the oxygen percentage exceeds 40 an electric spark produces a violent explosion.[17] Experiments have failed to reveal detectable traces of ethylene after 1½ hours' continuous administration in a well-ventilated theatre. There is, then, no danger to be apprehended during ethylene anæsthesia if precaution is taken not to use a cautery, flame, or any source of electrical discharge in the immediate neighbourhood of the patient. Accidents due to neglect of this precaution have been recorded.

Ethylene has a slightly disagreeable odour, the strength of which seems to vary in different samples. Hewer[18] states that the gas made for him at St. Bartholomew's Hospital had a rather pleasant ethereal odour, differing from the pungent smell of imported ethylene. There are at present no standards of purity, but the manufacturers claim that they are improving their processes and obtaining a gas of better quality. Some patients object to the smell and also complain of an unpleasant taste in the mouth on recovery, others do not notice anything disagreeable during induction. The difficulty is overcome by induction with gas and oxygen, the change from this to ethylene being easily made. I confess that there were occasions at the beginning of this research on which I shared the dislike of the patient for this gas, and that the surgeons and I have not found ethylene to possess "a rather pleasant ethereal odour." My experiences with it, however, which corroborate those of other observers, persuade me that it is too valuable an anæsthetic to be condemned for this particular failing, and if the process of manufacture continues to improve there seems every reason to hope that this reproach may be entirely, or at any rate almost entirely, removed. In several of my cases a roseolous rash, similar to an "ether rash," has appeared very shortly after induction and has persisted for 10–15 minutes; in one of them it was vivid and affected the whole body. It does not seem likely that the presence of this rash is an indication of impurity in the gas, for it is known to occur commonly under ether and mixtures containing ether. Its presence, was, however, somewhat surprising, for I had not seen any record of it in the literature.

A mixture of 80 per cent. ethylene and 20 per cent. oxygen produces anæsthesia in mice and rabbits, but rats require a 90 per cent. mixture. In man, induction with 90 per cent. is rapid, consciousness being lost in one minute or less; the percentage of oxygen must then be gradually increased to 15 or 20; it is only in exceptional cases that more than 20 per cent. of oxygen can be given to adults. As with other anæsthetics, the nature of the operation and the type of patient are determining factors. The flow of the gases per minute through meters has been recorded in a few cases, examples of which are given in Table II.

TABLE II.

Sex.	Age.	Condition.	Operation for—	Injection.	Proportions of gases.
M.	56	Powerful build.	Injection of alcohol.	1/100 A.	40 lit. ethylene, 10 lit. oxygen.
F.	60	Frail.	Laparotomy.	1/100 A.	75 lit. to 21 lit. in 16 mins.
F.	47	Slight build.	Carcinoma mammæ.	1/6 M. 1/100 A.	Average per cent. Oxygen = 26·3.
F.	24	Muscular.	Rad. cure of ing. hernia.	1/100 A.	30 lit. to 12 lit. in 6 mins.

The relative proportions of the gases flowing through the sight-feed mixing chamber of the apparatus have been determined as accurately as possible; analysis of the gases taken from the face-piece during inspiration and expiration were made in two cases (Table III.).

TABLE III.

Sex.	Age.	Operation for—	CO_2.		O_2.	
			I.	E.	I.	E.
F.	31	Varicose veins.	2·5	3·0	27·8	22·5
F.	30	Thoracoplasty.	2·7	2·8	28	21

Luckhardt[19] finds that an average of 87·6 per cent. ethylene was used in 800 cases. It will be seen that this compares very favourably with nitrous oxide, but unfavourably with acetylene and propylene, and although 1100 cases have been anæsthetised at the Presbyterian Hospital, Chicago, without a fatality or any condition arising which was considered serious, it is no less true that an average of less than 13 per cent. of oxygen represents a shortage of oxygen, and signifies that wise selection of cases and careful and skilful anæsthesia are essential. The respiratory centre is paralysed by an overdose; artificial respiration restores breathing in the normal individual. Death takes place from failure of respiration.

The attempt to obtain satisfactory anæsthesia must not be met by cutting down the oxygen supply, but either by a preliminary injection of morphine or the addition of ether, very small quantities of which are needed to convert a refractory into a placid patient. High blood pressure, arterio-sclerosis, emphysema, myocarditis are conditions which contra-indicate the use of ethylene, for although the normal individual can withstand a cutting down of oxygen for a considerable time, the handicapped patient is seriously embarrassed, and not only does he run an undue risk during anæsthesia, but his recovery is prejudiced by the starvation of the central nervous system of oxygen and the strain thrown upon his cardio-vascular system by cyanosis. It is necessary to lay stress upon these dangers, not because they are not known but because they are in danger of being forgotten. If ethylene is to be adopted at all extensively its limitations must be known. It produces a degree of muscular relaxation which is definitely superior to that of nitrous-oxide-oxygen but much inferior to that of ether.

The operations in which I have used ethylene number 68, five being dental extractions. This is a small number, but sufficiently large to allow of a definite opinion of its value being formed, including, as it does, in adults, 10 operations for hernia, 11 on the limbs, 5 amputations of the breast (1 double amputation in a male), 4 thoracoplasties, 3 for pulmonary tuberculosis and 1 for pulmonary abscess, 3 laparotomies, 1 phrenicotomy, and removals of glands, testicles, hydrocele, &c. In one laparotomy no ether was used, in one ether was used for about a minute at the start of the peritoneal suture, in the other ether was substituted for ethylene. In children 15 operations have been done for hernia, tuberculous glands of neck, &c., the youngest child being aged 11 months.

Relaxation has been almost uniformly good. In addition to the cases already mentioned, ether was added in four other cases for a few breaths—e.g., during the skin incisions of amputations of both breasts in a robust male. A preliminary injection of morphine, gr. 1/6, has been given in 26 cases, partly with the object of calming a highly nervous patient and at the same time of supplementing the action of ethylene, but chiefly in order to ensure a recovery free from pain following extensive operations.

One child, aged 14 months, developed bronchitis after an operation for bilateral inguinal hernia; no other complications occurred. Albuminuria and glycosuria have not occurred. Acetone was smelt in the breath of two patients on the day following operation, and the urine of a child contained diacetic acid. No systematic examination of the urine has been made. Vomiting occurs commonly during the return to consciousness and does not, as a rule, recur; ten patients vomited more than once, two of these severely. Thus the great majority of patients make an excellent recovery and are ready in a short time to take food or liquid. Oberhelman and Dyniewicz [20] found that the increase in blood-sugar and decrease in alkali reserve were less with ethylene than with ether, chloroform, or nitrous oxide: at no time in uncomplicated conditions did the change approach a dangerous level.

III.—PROPYLENE.

This gas, C_3H_6, which is colourless, has an odour somewhat resembling that of ethylene. Its density compared to air is about 1·7, boiling-point is −48·2° C. It is soluble in water, 100 volumes absorbing 44·6 volumes at 0° C. Absolute alcohol dissolves 12–13 volumes. It is liquefied at ordinary temperatures by a pressure of 7–8 atmospheres; 8 oz. of liquid propylene correspond to 100–110 litres of the expanded gas. Using cats as experimental animals, Easson Brown [21] found that concentrations of propylene varying from 50–37 per cent. produced good anæsthesia in a few minutes. Maintenance was carried on with 20–30 per cent. without any signs of poisoning. With concentrations of over 70 per cent. there was a fairly rapid fall of blood pressure. Anæsthesia was induced in man in two minutes with a 50 per cent. concentration; recovery was rapid, without any unpleasant after-effects.

The results obtained by Prof. Pembrey and myself with rats, a cat, and rabbit, using different concentrations, were satisfactory both as regards anæsthesia and freedom from signs of irritation; recovery was rapid. Propylene was then given to three adults, after a preliminary injection of atropine, two of the operations being for inguinal hernia, and one for the removal of a nævus; two of the patients were men of powerful physique. In all cases marked flushing of the face, neck, and chest followed induction; it gradually subsided. Consciousness was lost rapidly; in one patient unconsciousness came on after the second breath. Relaxation was good. Salivation, and in one case also lacrymation, was profuse. Recovery was quick, but less rapid than after ethylene. No vomiting, nausea, or broncho-pulmonary sequelæ occurred. The investigation was suspended at this stage until, by improved methods of manufacture, all impurities could be removed from the gas, for it was considered likely that the occurrence of these signs of irritation was due to the presence of unsaturated alcohols or aldehydes.

I wish to acknowledge my indebtedness to Dr. J. H. M. Campbell and Messrs. Skelton-Browne and Kanaar for undertaking gas analyses, and to the latter two for valuable assistance in other directions.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF ELECTRO-THERAPEUTICS.

A MEETING of this Section was held on May 15th, Dr. STANLEY MELVILLE, the President, being in the chair, when the adjourned discussion on

High Voltage and Radio-therapy

was continued.

Dr. J. H. D. WEBSTER, in presenting a résumé of his previous paper,[1] remarked that the method of prophylaxis by means of intensive therapy had been violently attacked abroad; the question was whether the poor results there obtained were in some way dependent on the malnutrition of the patients following the war years. Other observers had claimed good results from one or two applications administered through wax, but on the whole he agreed that the medium voltage was best for prophylactic purposes. In his opinion, Dr. Gilbert Scott's method of general radiation was inadequate. The work of Sampson Handley had shown that any prophylactic treatment must be applied in advance of the appearance of physical signs and that the supraclavicular triangle was an essential danger zone. Yet this zone received the least amount of treatment in Dr. Scott's method. With regard to the question of a "stimulation dose" of radium, Dr. Webster had seen several cases where radium had been the apparent cause of a widespread recurrence all round the area treated. Radio-therapy must work hand in hand with pathology in all its branches, including morbid anatomy, histology of new growths, and the biochemical changes in the body.

Dr. GILBERT SCOTT pointed out that the effects of radio-therapy were both direct and indirect. At the present time it was possible to get any desired dose for surface treatment, and yet the position was unsatisfactory; radiologists could not expect to be satisfied with their treatment of deep tumours. Prophylaxis was very complicated because there was nothing tangible to treat; it was therefore necessary to assume the worst and endeavour to deal with a patient as if he had potential stray metastases all over his body. On such a hypothesis it would be wrong to restrict the treatment to any localised area. The indirect effect was concerned with stimulating nature to destroy the pathological cells herself. It should be possible to catch these cells while they were few and isolated, and to that end his method was directed. He admitted it was crude, but he was doing his best along those lines, and he combined it with local treatment. Nodules were liable to develop just outside the area which had been radiated, and it was therefore a mistake to treat in too local a way.

Prof. S. RUSS said that although it might be difficult to be sure of the indirect effects of radiation in patients, it was easy to get proof of them in animal experiments. A big dose could lower the resistance of an animal to an implanted growth while repeated small doses increased the resistance. The line along which deep X ray therapy had developed was that of the large dose; he thought that the best criterion was not the dose that would prevent the growth of cells, taking no account of the resistance of the individual, but the minimal dose consistent with a beneficial effect. The development of more penetrating radiations had gone ahead without sufficient experimental warrant.

Dr. ROBERT KNOX read a paper on the

Nature of Tissue Response to Radiations.

He said that the problem was in no sense strictly physical. It was of no use to produce higher and higher voltages or increasing quantities of radiation. There was a third factor which was a fundamental consideration—namely, the type of cell to be dealt with the phase of its activity at the time of exposure, and the fact that the response of normal tissues played a vitally important part in the treatment of disease. Attention must be centred on the cell as the ultimate biological unit, and in this connexion the blood was worthy of more observation as a valuable guide in therapy. A complete blood-count should always be done before any treatment was initiated. Abnormal types of cell, such as myelocytes, were far more susceptible to electro-therapy than the more fixed forms. Illustrating the "indirect effect," Dr. Knox showed a number of charts demonstrating the continued diminution in the white blood cell-count in leukæmic cases after the cessation of treatment. He was in sympathy with Dr. Scott's method and was convinced that something on those lines would prove an important development in radiation therapy in the near future, particularly in the prophylactic treatment of carcinoma. Therapy should aim at control rather than at a knock-out blow. It was possible so to sensitise the tissues with a course of radiations that an alteration in the quality and voltage would then be followed by a striking result.

---

[1] THE LANCET March 28th, p. 661.

Dr. G. W. **MITCHELL** said that he had never seen a case of stimulation or acceleration of a growth due to radiation. He objected to the use of the term "prophylaxis" when dealing with "recurrence." He believed that much harm had been done by the intensive treatment; he had given up the lengthy periods of application and now distributed the doses over two or three days, often giving seven or eight treatments. He described various cases which had been successfully treated in this way. He expressed his belief in the method of widespread treatment in the prevention of recurrences.

Dr. N. S. **FINZI** said that radiation treatment was at present in a state of flux. It was very important to decide whether a neoplasm was originally a local disease, only subsequently becoming generalised, as was usually stated, or whether it was a general disease, as suggested by Thurstan Holland and Dr. Scott. He asked whether the generalised treatment for carcinoma had ever been successful; cases treated by X rays and radium often remained well for many years. It appeared that the softer radiations did not do so well in carcinomata nor endotheliomata; for these conditions radium or mixed treatment should be used, the X rays alone being more suitable for sarcoma. Epithelioma of the tongue, particularly, showed very bad results if treated with radium, although recent reports from Paris showed more satisfactory statistics. Lymphosarcoma responded readily to any type of ray. Local treatment of growths and also of metastases was successful in a certain number of cases if applied over a wide enough area. It must be admitted that intensive treatment was dangerous, but it was an attempt to deal with a dangerous disease. Cases should be grouped as to whether the aim was palliation or destruction of the growth. In the first group, Webster's method was satisfactory; in the second group more penetrating methods should be employed. When very penetrating radiations were used a late effect was found to occur, some months after, and this must be remembered when another kind of treatment was being applied after an interval.

The Prevention of Radiation Sickness.

Radiation sickness was now of infrequent occurrence except where the upper abdomen was being radiated, and then it was inevitable. To avoid it in other cases the room should be thoroughly ventilated, corona-less leads must be used, and the ends of the tube must be protected from corona; ozone and nitrous oxides must be expelled from the air of the room and chloretone administered. It was better not to give too much at one time; the treatment might be spread over days or weeks. The danger of harm to the lung was largely one of method; treatment of the mediastinum should be avoided where possible, but damage to the lung was not an inevitable result if care were taken.

Dr. F. **HERNAMAN-JOHNSON** agreed with Dr. Scott's method. He considered that in dealing with breast cases which had been operated on under favourable conditions it was not justifiable to take risks. Such patients had a fair expectation of life in any case, and the radiologist must not do anything to harm them. The basis of treatment should be the lines followed in dealing with tuberculous patients—i.e., attempts to raise the general resistance with special attention to the particular area under suspicion. He was accustomed to radiate widely, shielding the face only, with small doses, 1½ to 2 milliamps. with a 3 mm. filter for 10 to 15 minutes. Under such treatment tumours might entirely disappear and patients would say they felt much better and stronger. An effort should be made to treat the body as a whole, but the system would only stand a certain amount as shown by the blood effects produced by over-treatment. Sunlight and ultra-violet rays raised the blood-picture and courses of this treatment should alternate with exposure to X rays.

Dr. J. E. A. **LYNHAM** described the successful treatment of a case of tonsillar tumour with extensive involvement of the cervical glands. Preliminary treatment with X rays appeared to make the condition worse, but improvement immediately followed the insertion of radium needles in the throat. Possibly the earlier treatment sensitised the patient. The condition continued to improve after the suspension of treatment. Similarly, the best results in inoperable carcinoma of the uterus had followed the use of radium at the primary focus followed by wide irradiation of the pelvis. The size of the aperture appeared to have considerable importance, as revealed by experiments, on chemical solutions.

Replies.

Dr. **WEBSTER**, in reply, agreed that if the X ray bath were given over a wide area it must be given for a very limited period of time. Much depended on the total volume dose, which was very difficult to work out. He did not consider that Dr. Scott had established his views, and asked him to publish cases. In reply to Prof. Russ, he pointed out that the experimental evidence was concerned with implanted tumours; there was no evidence that generalised small doses improved spontaneous growths.

Dr. **SCOTT**, in reply, agreed that varying dosage was of great importance; it was a mistake to stick to one method only. He considered that by the time a cancerous patient reached the radiological department his disease was undoubtedly to be regarded as a general one. The aim of the radiologist should be to prevent distant metastases ever occurring.

BRISTOL MEDICO-CHIRURGICAL SOCIETY.

A MEETING of this Society was held at the University on May 13th, Dr. J. O. **SYMES**, the President, in the chair, when Mr. A. W. **ADAMS** read a paper on a case of

Fibrocystic Disease of the Humerus.

He introduced the subject by slides, showing the process of ossification at the epiphyseal line of long bones, a region particularly susceptible to disorders affecting growth, as well as to infections. Diseases of the osseous skeleton were then classified into age-periods, and also by ætiological factors. Twenty-eight slides were next shown to illustrate achondroplasia, rickets, multiple exostoses, septic infection of bone, syphilis, tuberculosis, osteitis deformans, and multiple enchondromata. Regarding primary and secondary neoplasms, Mr. Adams pointed out that quite good union might occur in a bone which had suffered a spontaneous fracture from neoplastic metastasis, and advised treatment of such fractures on usual lines. In the diagnosis of primary neoplasm of bone neither skiagraphic nor pathological evidence was so satisfactory as clinical experience. An illustration of one case of osteogenesis imperfecta and a skiagram of another were shown. Regarding osteitis deformans, of which a case was shown wherein one tibia only was affected, observed over a period of five years, the softening and bending were noted, and also the tendency for arrest of the process after a time; attention was called to the frequency of sarcoma occurring in such bones as a late phenomenon. The literature of fibrocystic disease of bones was reviewed and attention called to the frequency with which this affected one bone only, as compared to multiple cases. The comparative frequency of the affection arising in certain positions was observed, such being the upper end of the humerus, both ends of the femur, and the upper end of the tibia. Mr. Adams described his case, where the condition occurred in a boy at the upper end of the humerus and first seen 16 months previously; spontaneous resolution had occurred after three fractures. No treatment beyond splinting had been attempted. Mr. Adams thought such a course in this disease had not previously been described. He put forward the view that the disease tended to occur at joints allowing of rotatory movement, and suggested that repeated rotatory strains might be an element in ætiology. An endocrine factor had also been suggested.

Dr. T. C. BRENTNALL asked Mr. Adams whether it was indeed a fact that rotatory strains were greater at ball-and-socket than at hinge-joints. He thought that such joints as the shoulder, where rotation was a normal movement, suffered less trauma than hinge-joints from rotatory stresses.

Mr. A. R. SHORT mentioned another case of fibrocystic disease, of which they had seen the specimen that night; in this, both tibia and femur were affected.

Mr. C. A. MOORE referred to a case under his own care in which pathological evidence from different sources on the same piece of tissue was very varied. He agreed that spontaneous fractures due to neoplastic metastasis may be successfully treated on ordinary lines, and mentioned a case of simultaneous fracture of both femora treated in this way.

Reviews and Notices of Books.

CYTOLOGY.

The Cell in Development and Heredity. Third edition. By E. B. WILSON, Da Costa Professor of Zoology, Columbia University. New York: Macmillan Company. 1925. With 529 text-figures. Pp. 1232. 36*s.*

THE first edition, in 1896, had 371 pages and 142 figures. The present contains about four times as much. It is beautifully produced, and with a slightly larger page and rather smaller type it is less than twice as thick and weighs only 70 per cent. more. To commend its substance is superfluous. To English readers Wilson on the cell is *the* book on the subject, and in its new form it will continue to provide information, refreshment, and inspiration to those who go to it. Twenty-five years has been a long time to wait for a revised version, but the delay was perhaps wise. The rediscovery of Mendel's work coincided with the publication of the second edition in 1900, and the stormy metamorphosis of Prof. Wilson's subjects which ensued was hardly the time for stocktaking. Chromosomes and their manœuvres seemed at one time rather a dead topic. The wonderful concordance of cytology and the outward appearances of things which has been revealed in the meantime are the fullest justification of Prof. Wilson's persistent faith that there was more in them than there seemed. And he has provided once again one of those rare great books which are a starting-point for fresh knowledge, because they are a real statement of what is known. Every biologist should thank him.

PARASITOLOGY FOR MEDICAL STUDENTS.

By ALEX. MILLS KENNEDY, M.D. Glasg., Professor of Medicine, University of Wales; Honorary Physician, Cardiff Royal Infirmary. London: Humphrey Milford, Oxford University Press. 1925. Pp. 142. 10*s.* 6*d.*

Prof. Kennedy has found it advisable when teaching medicine to give demonstrations in order to recall to students the essential features of those parasites which are of practical importance from the point of view of the physician. In this little book, based on his clinical teaching, he has succeeded in presenting within the limited compass of 138 pages of text, richly supplied with illustrations, an account of the salient features and life-history of these parasites, and has added brief notes on the diagnosis, prophylaxis, and treatment of diseases caused by them. The six chapters are devoted to insects and arachnoids, tape-worms or cestodes, flukes or trematodes, round worms or nematodes, sporozoa, spirochætes, and fungi which are inimical to man. On the whole the teaching is that generally accepted. The author treats as separate and distinguishable three species of human pediculi, whereas we believe that modern zoological opinion recognises but one species. In the account of *Filaria bancrofti* no mention is made of thick films as being essential for the demonstration of this parasite. No mention is made of the newer methods of treatment of trypanosomiasis.

Parasitology in its application to medicine, especially tropical medicine, is a subject which, year by year, is looming larger in the curriculum. So many and diverse are the technicalities with which an undergraduate has little concern that a simple account of the more familiar parasites will be welcomed by medical students, and also by practitioners who have no time to study full monographs on the subject. Some of the microphotographs are quite excellent, notably those illustrating the first chapter. Others are less well reproduced, and this criticism applies especially to some of those depicting the various helminthic parasites. But here, as indeed elsewhere, the text is clear and easy to follow, even without pictures. We predict success for this handy little volume.

MICROBIOLOGY AND SEROLOGY.

Manuel Technique de Microbiologie et Sérologie. Par le Prof. A. CALMETTE, S. Directeur de l'Institut Pasteur; L. NEGRE et A. BOQUET, Chefs de Laboratoire à l'Institut Pasteur. Paris: Masson et Cie. 1925. Pp. 568. Fr.30.

THIS volume constitutes a compendium for those in charge of a bacteriological laboratory. Nothing, from the care of laboratory animals up to the preparation of antitoxic sera on a large scale, has escaped the attention of the authors. On all subjects they speak with authority. There has hitherto, to our knowledge, been no book available covering quite this field, and it should prove of inestimable value to all those charged with the ordering of a bacteriological laboratory, no matter how small or how large.

MEDICINE.

Manual of Medicine. Fifth edition. By THOMAS KIRKPATRICK MONRO, M.A., M.D., President of the Royal Faculty of Physicians and Surgeons of Glasgow; Regius Professor of Practice of Medicine in the University of Glasgow; Physician to the Western Infirmary. London: Baillière, Tindall and Cox. 1925. Pp. 1033. 25*s.*

IN the last edition have been incorporated new articles on lethargic encephalitis, seven-day fever, and tularæmia. The articles on diabetes and disturbances of the heart's action have been rearranged. There appears to be need for some rearrangement of the space allotted to certain sections; it is difficult to justify the allotment of 240 pages to diseases of the nervous system and only 110 to the digestive system, including the peritoneum. We have now such anomalies as the dismissal of cardiospasm in four and a half lines, whereas two pages are given to Landry's paralysis. We have read accounts of aphasia in other text-books which were fully as lucid and more in accordance with modern views than that here given. The revised section on diabetes would be improved by greater detail concerning the starvation methods of Graham and Allen; we are doubtful if any student could for himself work out an effective scheme of treatment from the description given in this book, but that could only be expected.

The volume would, we think, gain in value if the unillustrated section on skin diseases were omitted and the matters to which we have referred were revised in accordance with the space thus gained. The book is so helpful in most respects that meagre or too highly compressed sections are the more to be deprecated.

Nouveau Traité de Médecine. Edited by G. H. ROGER, F. WIDAL, and P. J. TEISSIER. Vol. XIV., *Digestive System.* Vol. XXII., *Muscles, Bones, and Joints.* Paris: Masson and Co. 1924. Each volume about 560 pages. Fr. 45. per vol.

THESE new volumes of the "Nouveau Traité de Médecine" conform to the high standard of their predecessors. They are profusely studded with plain and coloured illustrations, diagrams, and X ray photographs in such a manner as to give the reader an excellent survey of the diseases dealt with both from the pathological and clinical standpoints. The fourteenth volume completes the description of diseases of the alimentary canal, and is chiefly remarkable for the section on the pathology of the rectum, by R. Bensaude. Vol. XXII. will be found of value by all medical men interested in orthopædic problems. The section dealing with congenital dystrophies of bone, by O. Crouzon, is particularly instructive, and gives beautiful illustrations of such rare conditions as cleido-cranio dysostosis and the Klippel-Feil syndrome. The article on Rickets, by Prof. L. Spillman, of Nancy, forms an admirable survey of existing knowledge of the subject.

We are again able strongly to recommend this treatise to our readers.

PHYSIOLOGY.

An Introduction to Recent Advances in Comparative Physiology. By L. T. HOGBEN and F. R. WINTON. London: W. Collins and Sons. 1925. Pp. 242. 25*s.*

WHETHER form determines function or function form is as insoluble a problem as whether the owl or the egg came first. The classical comparative anatomist has not paid as much attention to physiology as he might, and the purest physiologists have shown a tendency to put structure by and pass histology over to the anatomists. Most common men have been content with the obvious fact that structure and function are insolubly connected with one another, and there has been in recent years a rapidly growing conviction that the methods of thought and action developed in modern physiology might with advantage be extended and applied to live organisms with a wider variety of anatomies than is shown by mammals and the frog. Hence we have the Society and *Journal of Experimental Biology*, and the permeation of zoological literature with physiological conceptions. The present admirable series of essays will convince any sceptic that the movement is a good one, from which much fruit may be anticipated. The book is no attempt at a systematic survey, but, in imitation perhaps of the Recent Advances in Physiology and Further Advances which Dr. Leonard Hill organised so successfully some 15 years ago, deals with a series of interesting topics chosen partly because they represent growing points, and partly because the authors felt moved to write about them. The chapters are on the fertilisation of the egg, the development of the individual, sources of vital energy, the mechanism of response, coördination, behaviour in animals, hereditary transmission, the material basis of inheritance, and the determination of sex. The last three are perhaps over-written subjects just now, but in all the essays the zoologist will find information brought in from human physiology, while the human physiologist will learn how extraordinarily curious and interesting are some invertebrates, and may appreciate the extent and fascination of the unworked field which lies among them. The writing is clear and easy to follow.

DEVELOPMENTAL ANATOMY.

A Text-book and Laboratory Manual of Embryology. By LESLIE B. AREY, Professor of Anatomy at the Northwestern University Medical School, Chicago. London and Philadelphia: W. B. Saunders Company. 1924. Pp. 433. 27*s.* 6*d.*

THIS volume is at first sight but a new and slightly varied edition of Prentiss and Arey's well-known manual, but a closer inspection shows that Prof. Arey's statement in his preface, that in plan and content the work is essentially new, is justified. We are glad to see a recognition of F. M. Balfour's fundamental work in this book. A good, though short, account of changes in form during growth is given. Many of the excellent illustrations are taken from Prentiss and Arey, and these, with the new drawings, form a valuable part of the work. Figs. 6, 166, and 312 require some editorial attention, as do also parts of the text. No normal human heart goes through such developmental stages as are shown in Kollmann's figures, reproduced in Fig. 177 of this work; such figures ought to be relegated to obscurity. These faults are minor matters, hardly detracting from the general excellence of the book, which we recommend without hesitation to students as a good and very readable treatise.

LEEDS PHILOSOPHICAL AND LITERARY SOCIETY.

The History of 100 Years of Life of the Leeds Philosophical and Literary Society. By Lieut.-Colonel E. KITSON CLARK, Hon. Secretary. Leeds: Jowett and Sowry, Ltd. 1924. Pp. 249.

THE Leeds Philosophical and Literary Society was founded in 1818 mainly owing to a letter to the *Leeds Mercury* by Edward Baines, jun. (afterwards Sir Edward Baines). Colonel Kitson Clark quotes the letter in full, and considering that it was written by a boy aged 18, its style and matter are astonishing to read nowadays. To take one passage:—

> "In the full possession of youthful vigour, and in the unrestrained flow of intellect and imagination, how can a young man be more usefully or honourably employed than in the acquisition of knowledge, which must render him respectable and superior in life, and in the cultivation of those noble powers which alone exalt man to an infinite height above the brutes. . . ."

Incidentally such a style must have been fairly common among the educated young at the beginning of the last century, for some of Jane Austen's incomparable young women talk in the same way. The society being formed naturally desired a building wherein to meet, and such a building was accordingly erected in Park Row and opened in 1821. The first report of the society contained some information which will surprise no one—namely, that the original estimate for land and building which had been £4000 had been exceeded by at least £1000. This deficit was made up by the generosity of two members, Mr. J. Marshall and Mr. Benjamin Gott.

Colonel Clark's history is very complete; he gives a list of all the original members, with many extracts from the annual reports, and comments thereon, together with some account of the various lecturers and their lectures. In one place we fancy that owing to a natural desire to exalt the year 1818 he has erred, for he says on p. 2 of that year that "Turner and Landseer were at their zenith." The former we should say was at his great period from 1820 to about 1840, but Edwin Landseer was only 17 in 1818, and John Landseer, Edwin's father, is chiefly known by his engravings after his son's pictures. Colonel Clark gives a full list of all the lectures delivered and papers read before the society from 1819 to 1920, which makes most interesting reading. The society appears to possess a historian worthy of its well-deserved renown.

AN OUTLINE OF ENDOCRINOLOGY.

By W. M. CROFTON, B.A., M.D., Lecturer of Special Pathology, University College, Dublin; Pathologist, Dr. Steevens' Hospital, Dublin. Edinburgh: E. and S. Livingstone. 1924. Pp. 126. 6*s.*

THIS book contains the substance of the lectures Dr. Crofton has delivered annually at University College, Dublin, since 1910. It consists of ten chapters, of which the first six are devoted respectively to the pineal, pituitary, suprarenal, thyroid, parathyroid, and thymus glands. Chapter VII. deals with the gonads, Chapter VIII. with the hormones of the gastro-intestinal tract, and Chapter IX. with the pancreas, while the last chapter is entitled Epilogue. The subject-matter is illustrated throughout by reference to clinical examples and has been brought well up to date. Indeed, in some places, notably Chapters IV. and IX., the results of recent and as yet uncontrolled work are accepted without reserve. The volume is handy, easy to read, and is written in an attractive style. The closing chapter dealing with theoretical conceptions is in parts not easy to follow. The illustrations are well chosen and for the most part new.

THE ENGINES OF THE HUMAN BODY.

Second edition, revised and enlarged. By Sir ARTHUR KEITH, M.D., LL.D., D.Sc., F.R.S., Conservator of the Museum and Hunterian Professor, Royal College of Surgeons. London: Williams and Norgate. 1925. Pp. 343. 12*s.* 6*d.*

Prof. Keith's book embodies the Christmas lectures delivered to an audience of boys and girls at the Royal Institution in 1916–17, and this second edition has increased by 60 pages without increase in price. In the meantime the author has become secretary of the Institution and his services to anatomy publicly honoured. The increase in size is due to the necessity of expanding certain growing subjects, such as the muscles of athletes, thinking and health, vitamins, insulin, and hormones, and the human body as a society of microscopic units. The additions are mainly to be found in appendices. In its new form the book, while scrupulously based on the facts of structure, goes far to redeem anatomy from the stigma of a dull subject and anatomists from being dull fellows. In every page structure is correlated with function in such a way as to make the workings of the body clear to the unlearned, whether or not they have outgrown girlhood and boyhood.

JOURNALS.

BRITISH JOURNAL OF OPHTHALMOLOGY. April–May.—In the April issue Prof. Schiotz gives fresh corrected graphs to be used with his tonometer. At present, unfortunately, tonometers are not all similarly adjusted. A centre has been established at Oslo where this can be done, whence also adjusted tonometers can be obtained.—Prof. O. Leser, of Prague, writes on the Development of the Extra-ocular Muscles in Some Mammals, and W. Gordon Byers on cases of Traumatic Keratitis in the New-born, a condition which, by means of the slit-lamp, is now proved in the living subject, as it had been already proved post mortem, to be due to the rupture of Descemet's membrane.—W. S. Duke-Elder writes on Changes in Refraction in Diabetes Mellitus. His principal conclusions are: (1) In diabetes sudden changes of refraction occur. In the course of the disease with high or increasing sugar, myopia tends to occur; with decreasing sugar, and therefore usually just after the onset of energetic treatment, hypermetropia tends to occur. (2) The phenomenon is due to osmotic processes involving the lens, caused by a variation of the molecular concentration of the blood and tissue fluids with the sugar-content. (3) In both cases the tendency is to recur to normal: in the first under general diabetic treatment; in the second on the establishment of metabolic stability.——In the May issue G. Riddoch and C. Goulden write on the Relationship between Subarachnoid and Intraocular Hæmorrhage. This is a reprint of a paper read before the Ophthalmological Section of the Royal Society of Medicine in June, 1924. About the same time Leslie Paton read a paper on the same subject to the Ophthalmological Society.[1] They should be read together. Appended to the present paper is a bibliography containing references to 67 previous writings on the subject, mostly by neurologists and ophthalmologists.—David Priestley Smith carries on the traditions of a well-known name in his article on Centripetal Fan Scotoma in Glaucoma. It includes charts of several cases of chronic glaucoma showing a scotoma tapering from the periphery of the field towards the fixation point, and not connected with—nor leading towards—Mariotte's blind spot. To discover these scotomata in early typical cases it is almost essential to use the circular method in perimetry. The borders of the area of maximum blindness are more radial than concentric, and, of course, the border is more accurately located when the test objects meet it at something like a right angle.—I. Abramovitz, of Vilna, records a case of such severe injury to the eye from liquid ammonia (10 per cent.) that it had ultimately to be eviscerated. The ammonia had been awkwardly administered during a fainting fit, and the liquid had flooded the eyes.

THE VETERINARY JOURNAL for April is made up of 22 articles by various medical and veterinary authors on the subject of tuberculosis in all its phases. Articles on the Prophylaxis of Bovine Tuberculosis by Vaccination by Mr. Guérin, of the Pasteur Institute at Lille, and Dr. Nathan Raw, advance promising views. In neither case has trial lasted a sufficient time to speak of definite result, but the authors have made out an a priori case for further trial in dairy herds.—The Danger of Tuberculous Milk as a Risk to Man is dealt with by Dr. Stanley Griffiths, and the Eradication of Tuberculosis from the Milk-supply has a number of articles under the respective authorships of Colonel J. W. Brittlebank (Manchester), Dr. John Robertson (Birmingham), Dr. A. Stenhouse Williams (Reading), Prof. J. Lyle Cummins (Cardiff), Mr. Male, and others.—The Veterinary Inspection of Cattle for the Eradication of Cows with Tuberculous Udders is advocated by Messrs. Lloyd, Burndred, and Pollard, the municipal veterinary officers of Sheffield, Blackburn, and Halifax respectively, whilst the prevalence of the disease in the pig, dog, cat, guinea-pig, and rabbit receives mention from the pens of Messsrs. Mayall and Gray, who are veterinary practitioners.—The views of Prof. Moussu, of the Paris (Alfort) Veterinary School, on Anti-tuberculosis Vaccination, as at the Present Time Applied in France, are given in an article translated from the *Recueil de Médecine Vétérinaire*, and other aspects of the question are dealt with in abstracts from current literature. The special number is worthy of perusal by all who are interested in public health work.

---

PROCEEDINGS OF THE ROYAL COMMISSION ON NATIONAL HEALTH INSURANCE.[*]

(Continued from p. 1098.)

EVIDENCE OF VARIOUS APPROVED SOCIETIES.

Prudential Society.

(App. XXI. and Q. 9627–9786.) Mr. R. J. Meller, M.P., and Mr. E. F. Spurgeon gave evidence, and said that they had not much to add to that of the National Conference of Industrial Assurance Approved Societies. The Prudential Approved Societies, four in number, have a total membership of over 3 millions. Interesting sickness experience tables show the actual as a percentage of the expected sickness for five years; for 1923 the figures were 63 per cent. for men and 83 per cent. for women. The witnesses were of opinion that there had not been a long enough normal period on which to base estimates for future rates.

They advocated giving insured women on marriage the option of (1) a cash bonus to terminate their insurance, or (2) a continuous insurance, with the ordinary "free year," &c., instead of the special benefits at present provided. Treatment benefits, in particular dental benefit, should, they thought, be rendered available for all insured persons, and should be financed through the existing Central Fund, the first charge on which should be, as at present, the meeting of societies' deficiencies. Such treatment benefits (e.g., dental benefit) should be minimum benefits and capable of being supplemented by societies having surpluses remaining after paying their contribution to the Central Fund. For this reason, amongst others, these treatment benefits should be administered by the Approved Societies and not by the Insurance Committees.

As regards the medical service now provided, Mr. Meller said:—

> I think the medical service is vastly improved from the earlier days, but I think it still falls far short of what medical service should be; not so much from the point of view of the incompetency of the practitioner, but from the point of view of the narrowness of the service which is given.

National Amalgamated Approved Society.

(App. XXV. and Q. 10390–10636.) The evidence of this Society (Sir Thomas Neill, Mr. Farmer, and Mr. Pike) was on somewhat similar lines to that of the Prudential. Membership, 2¼ millions. Investments, nearly £11,000,000. Sickness experience of men in 1923, 67 per cent. of expectation; of women members, 101 per cent. The disablement benefit of women has been no less than twice the expectation.

The Society drew special attention to the heavy burden on the funds due to tuberculosis, and suggested that the Commission should invite particulars from societies generally, and give publicity to the facts and so help to concentrate public opinion on the need for more closely tackling this disease and possibly for compulsory segregation. As regards "additional benefits," a substantial part of this Society's surplus had been devoted to contributions to the voluntary hospitals. Of the treatment benefits, dental treatment came easily first, and the Society is spending £90,000 per annum on it. Of every 100 applications now being received for the following treatment benefits the proportions in each case are:—

Dental	71
Optical	18
Convalescent home treatment	7
Medical and surgical appliances	4

With regard to medical benefit, the witnesses considered that Medical Service Subcommittees are satisfactory. In the refereeing of special benefit claims the procedure followed was to get a "Harley-street man" to select suitable cases for reference, and send them to the Regional Medical Officers of the Ministry.

United Women's Insurance Society.

(App. XXIV. and Q. 10174–10389.) Lady Emmott, Chairman, and Mr. Alban Gordon, Secretary, gave evidence. The Society has 54,000 members, two-thirds of whom are domestic servants and the remainder clerks, nurses, and shop assistants. Its sickness and maternity experience has been light, and the outstanding feature of the Society's administration was the early use made of Section 21 (subscriptions to a charitable organisation) for providing dental and other benefits to its members. A separate organisation was brought into being in 1914, called the United Women's Benevolent Association, for the purpose of providing these extra benefits.

The Society, in this way, has had ten years' experience of a dental scheme. Full details, scales of pay, &c., are given. The benefit includes all surgical dentistry free and half cost of dentures. It has been provided through a central clinic in London and a panel system in the provinces. The tables given show a total expenditure on dentistry of £41,000 and a consequential saving of sickness benefit and disablement benefit estimated at £14,000. It is considered that the gross total cost of an all-in scheme of dental benefit should not exceed 5*s.* 3*d.* per member per annum, of which a substantial portion could be recovered from the individual member.

It was agreed that schemes under the section referred to might properly be subject to more control by the Ministry of Health. In fact, if dental treatment were to be a benefit under the Act, it might suitably be administered by the Insurance Committees.

As to panel as opposed to clinic treatment the evidence contains the following:—

> With regard to administration through private dentists or panels of dentists, the great difficulty to be contended with is that caused by the practitioner who either states, or more generally implies, that the article which he will furnish under the panel scheme would be distinctly improved upon by the payment of a small supplement by the member. Even graver and more difficult to cope with is the tendency on the part of the less scrupulous practitioner to indulge in the more profitable work of extractions and provision of dentures rather than the more arduous but more beneficial conservative work which is generally recognised to be the better from the patient's point of view.

This Society considers that there should be a comprehensive medical service, and with regard to the present system of contributing to hospitals out of surpluses, it expressed profound dissatisfaction.

> Owing to the attitude adopted by the authorities of the majority of hospitals, such payments are a benefit to the hospital without being a benefit to the member, because the hospitals receiving such a payment from the Society do not accept this as being made on behalf of the member, but still require her to contribute the same sum that she would have contributed had the Society not made a payment on her behalf.

National Conference of Friendly Societies.

(App. XXVI. and Q. 10637–11027.) This evidence (Mr. J. W. Shaw, Mr. A. J. E. Saunders, and Mr. W. Marlow) covers similar ground to that already given by the large Friendly Society orders—a proposed limitation of cash benefits, the need for a scheme of dental treatment (with a possible limitation to one-half of the cost in the case of dentures), and general objection to the pooling of surpluses.

---

[*] In previous articles the proceedings of the Commission were reported under the following headings: Introductory Note; The Scope of the Insurance Scheme (see THE LANCET, Jan. 31st, pp. 247–8); The Provision of Medical Benefit (Feb. 7th, pp. 301–3; Feb. 14th, pp. 355–6; Feb. 21st, pp. 403–5); Financial Provisions of the Act (Feb. 28th, pp. 454–7); Medical Certification and the Regional Medical Staff (March 7th, pp. 508–9); The Approved Societies and the Money Benefits (March 14th, pp. 564–5; March 21st, pp. 623–4); Evidence of the Hearts of Oak Society (March 28th, pp. 677–9); Evidence of the National Conference of Industrial Assurance Approved Societies and of the Manchester Unity Approved Society (April 4th, pp. 731–3); Evidence of Independent Order of Rechabites, of Rational Association Friendly Society, and of Miners' Societies (April 11th, pp. 784–6; April 18th, p. 839); Evidence of Mr. Alban Gordon (April 18th, pp. 839–40); Evidence of Joint Committee of Approved Societies, of Stock Exchange and Lloyds' Health Insurance Societies, and of Group of Catholic Approved Societies (April 25th, pp. 889–91); Evidence of the National Insurance Beneficent Society (May 2nd, pp. 943–4); Evidence of the British Medical Association (May 9th, pp. 993–5); Evidence of the British Dental Association and other Dental Organisations (May 16th, pp. 1044–6); Evidence of the Insurance Committees (May 23rd, pp. 1097–8).

References to the paragraphs in the printed statements issued as appendices to the reports of the oral evidence are given thus; "App. X. 69," and references to the oral evidence thus—Q. 1369.

As regards the medical service for the insured, it is pointed out that if there was a mere extension of the present service to dependants of insured persons, this would (*a*) greatly intensify the overlapping of services already existing; (*b*) be extremely costly, because a large number of panel practitioners would be, in effect, working full-time on payment basis devised for part-time work; (*c*) leave out of the scheme at least 1½ millions of persons, including not only the destitute, but a number of non-insured persons such as hawkers, small shopkeepers, and others.

It is therefore suggested that the best way of organising the provision of medical treatment is to merge all existing forms of public medical service (including medical benefit under the National Health Insurance Acts) into one National Medical Service, thereby creating one unified organisation for the prevention and cure of disease. It was realised that this was an ideal not capable of being immediately put into practice. The conference was of opinion that in the meantime consultant and specialist services should be provided for insured persons.

Other Societies' Evidence.

Other evidence given prior to the presentation of that submitted on behalf of the medical profession was as follows:—

Seamen's National Insurance Society (App. XXXI. and Q. 11906–12236).—Sir Norman Hill explained the exceptional needs of the sea service, and the special arrangements in force for attendances at the various ports by specially engaged doctors paid according to an agreed scale; the system has worked well and there has been no cause of complaint. He suggested a new method of collecting contributions in respect of foreign-going seamen, to stop the deplorable loss of contributions which was going on at present. Sir Norman Hill also gave evidence as to the Lascar fund which is fed by contributions in respect of foreign domiciled seamen; 600 pensions are offered each year out of the fund and grants are made also to seamen's hospitals.

National Federation of Rural Approved Societies (App. XXIX. and Q. 11393–11750) and the *Scottish Rural Workers' Approved Society* (App. XXX. and Q. 11760–11905).—The Federation's evidence contains some rather general criticisms of the doctors for failing to observe the certification rules, suggests that panel doctors are mostly overpaid and that the capitation fee should diminish on a scale after the number of insured persons on a doctor's list exceeds 500, and complains of the inadequacy of the reports of the Regional Medical Staff. The Scottish Society's evidence includes a proposal that complaints in regard to certification should be dealt with by the Scottish Board of Health direct instead of under the present cumbersome machinery.

National Federation of Employees' Approved Societies (App. XL. and Q. 13143–13441).—This Federation includes societies of the Employers' Provident Fund type. Mr. Lesser gave evidence. The Federation is opposed to any fundamental reconstruction of the national health insurance scheme such as administration on a territorial basis through local authorities; it does not consider that experience at present is sufficient to justify dental treatment as a normal statutory benefit. As regards the medical service under the Acts, it is stated that these societies have almost daily experience of the need for supplemental services, although some of the most necessitous cases can be relieved by referring members to institutions to which the societies contribute.

Royal Insurance Officials' Benevolent Association (App. XXVII. and Q. 11028–11201).—This Association would prefer to remain under the National Health Insurance Acts if the surpluses of the Society can be fully secured to its own members. At the present time, within a short period of a member qualifying for additional benefits, he ceases to be insurable and loses all title to share in the disposal of the surplus he has helped to build up.

MEDICINE AND THE LAW.

THE ABRAMS SYSTEM IN THE LAW COURTS.

THE High Court of New Zealand made an order in March last for removing from the Medical Register the name of Dr. Dundas Mackenzie, an exponent of the Abrams system of diagnosis and treatment. The hearing of the proceedings occupied nine days and attracted considerable attention. From newspaper reports now available it is at length possible to obtain a clear idea of the charge, the evidence, and the judgment in the case. As we have not yet had a test case in the law courts of this country, it is perhaps worth while to record what has happened elsewhere.

The charge of infamous conduct, which the High Court of New Zealand has held to be proved, was not based upon the mere use of the Abrams system. The Medical Board which initiated the proceedings did indeed suggest that no scientific foundation has yet been established for Dr. Abrams's claims; but the Board's contention was that, whether the system was genuinely valuable or not, this particular exponent had used it as a medium for perpetrating a fraud on the public. The specific charge was that he practised the system "in such a manner as to show that he could not honestly have believed that that method of treatment and diagnosis was a reliable and useful one in the case in which he employed it." The evidence in support of this allegation related to some 20 cases. It indicated that Dr. Mackenzie (who admitted in the witness-box that he had claimed to be a cancer specialist though he had had no special training to support the claim) had told patients not only that they had cancer, but they had it in an aggravated form—and this without a shadow of justification. He repeatedly stated that his system would cure and that other treatment would fail. Conversely, Dr. Mackenzie had announced that a woman had no sign of the disease, though two well-known Auckland doctors had diagnosed cancer. Those doctors, he said, were butchers who should not be allowed to practise; the lady merely had some minor trouble which he could easily cure with about 30 treatments. At the end of the period he told her husband that she was cured. Soon after she was found to be in an advanced state of cancer; there was an operation, but she died a few days later. Interspersed amongst evidence of this tragic character there were ludicrous incidents of blood sample tests of lamb's and donkey's blood which had been sent to Dr. Mackenzie as human specimens and which elicited remarkable diagnostic results. Professional witnesses, if they displayed any scepticism towards the Abrams system, were confronted in cross-examination with enthusiastic views attributed to Sir James Barr and the more guarded opinions of Sir Thomas Horder were quoted. After a patient hearing the High Court came to the conclusion that only one inference was possible—namely, that Dr. Mackenzie had no honest belief in the usefulness and reliability of the system which he practised. In the words of the judgment delivered by Mr. Justice Herdman, if a practitioner leads the public to believe that a system in which he has no faith can detect disease and can be used to check or cure disease, then he is not acting honestly and in good faith, and his behaviour brings itself within the phrase "infamous conduct in a professional respect."

In fairness to Dr. Mackenzie it should be stated that evidence was tendered on his behalf to prove that his treatment had effected cures. But the Court observed that this evidence was not supported by the witnesses' former medical advisers, and added that there was no conclusive or convincing proof that cure or improvement was due to the Abrams treatment. In fairness, too, to the Abrams system itself, it must be repeated that the merits of the electronic theory and the oscilloclast were not the primary issue in the case. On the other hand, the one solid inference established by judicial inquiry in the proceedings in Dr. Mackenzie's case is the fact that the exponent who pressed the Abrams system upon the New Zealand public, and who practised it so extensively, did not really believe in it himself.

HARNETT *v.* BOND AND ADAM: JUDGMENT OF THE HOUSE OF LORDS.

THE House of Lords delivered considered judgments dismissing the appeal of Mr. W. S. Harnett against the decision of the Court of Appeal in his action against Dr. C. H. Bond and Dr. G. H. Adam arising out of the detention of the plaintiff at Malling Place, Kent, and elsewhere, and out of the course taken by Dr. Bond in causing his return to the licensed home kept by Dr. Adam, which he had left on probation.

The general outline of the case will be remembered. At the end of the trial before Mr. Justice Lush, the jury answered certain questions left to them by the judge, assessing damages against the two defendants jointly at £25,000. After argument Mr. Justice Lush entered judgment against the defendants jointly for £20,000, and in addition against Dr. Bond for £5000. The Court of Appeal directed that judgment should be entered for Dr. Adam and ordered a new trial in the case against Dr. Bond, and against this Mr. Harnett appealed to the House of Lords.

The Lord Chancellor, in giving judgment, gave an outline of the facts and referred to the questions answered by the jury:—

1. *Q.* Did Dr. Bond cause the plaintiff to be detained at the office until the attendants came for him ?—*A.* Yes.
2. *Q.* Did he cause him to be sent back for the purpose only of his being examined by Dr. Adam or for the purpose of his being detained at Malling Place ?—*A.* Being detained at Malling Place.
3. *Q.* Did Dr. Bond cause the plaintiff to be taken back ?—*A.* Yes.
4. *Q.* Was the plaintiff of unsound mind on Dec. 14th, 1912 ?—*A.* No.
5. *Q.* Was he fit to be at large ?—*A.* Yes.
6. *Q.* Was he dangerous to himself or others ?—*A.* No.
7. *Q.* Did Dr. Bond honestly believe that the plaintiff was of unsound mind ?—*A.* No.
8. *Q.* Or that he was not fit to be at large ?—*A.* No.
9. *Q.* Or that he was dangerous to himself or others ?—*A.* No.
10. *Q.* Did he believe that the plaintiff had escaped from his brother's charge ? If so, was that his reason for having him sent back ?—*A.* Yes.
11. *Q.* Did he take reasonable care to ascertain the true facts ?—*A.* No.
12. *Q.* Did he honestly believe that Dr. Adam had retained a power of taking the plaintiff back during the 28 days in the leave of absence order ?—*A.* Yes.
13. *Q.* Did Dr. Adam when he received the telephone message and sent the car honestly believe that the plaintiff on Dec. 14th was of unsound mind and unfit to be at large ?—*A.* Yes.
14. *Q.* That it was in his interest that he should be taken back to Malling Place ?—*A.* Yes.
15. Did he take reasonable care in acting as he did ?—*A.* No.
16. *Q.* Did he make it known to the plaintiff that he was liable to be retaken if his mental condition required it ?—*A.* No.
17. *Q.* Was the detention of the plaintiff at the Commissioners' offices the act of Dr. Bond alone or was it really the act of both the defendants ?—*A.* Dr. Bond.

It was common ground, Lord Cave said, that Dr. Bond acted for the reason given in answer 10, and not on account of any belief as to Mr. Harnett's mental condition referred to in answers 7, 8, and 9. Mr. Justice Lush had directed the jury that they might assess damages upon the footing that the whole of the confinement of the plaintiff after his return to Malling Place was a direct consequence of the defendants' acts on Dec. 14th, 1912, and as a result had given judgment for £5000 damages against Dr. Bond, and for £20,000 against both defendants. The Lords Justices had held, however, that the chain of causation had been broken at innumerable points after the date mentioned, and also that Dr. Adam, under the terms of the leave of absence order given to Mr. Harnett, was entitled to retake him within 28 days, if in his honest opinion it was necessary, and that there was no evidence of want of reasonable care on his part.

As to the case against Dr. Bond, Lord Cave had no doubt that if the jury's finding as to Mr. Harnett's mental condition on Dec. 14th, 1912, was assumed to be correct, Dr. Bond had no right to cause Mr. Harnett to be detained at the Commissioners' offices pending the arrival of the motor-car sent by Dr. Adam to fetch him back, and on this assumption Dr. Bond was liable for damages for that detention. The damages, however, must be confined to the direct consequences of such an act. It appeared to him to be impossible to hold that the detention of Mr. Harnett by Dr. Bond was the direct cause not only of his being retaken and conveyed to Malling Place, but also of his being confined in that and other houses until October, 1921. Dr. Bond could not and did not direct or authorise Dr. Adam to retake Mr. Harnett, and with regard to that retaking, to his confinement at Malling Place, and to his detention in the other places, where he was confined, each of these occurrences was a *novus actus interveniens* which broke the chain of causation. Further, there were the various examinations of Mr. Harnett by the proper authorities during the nine years of his confinement. It might be a question at the new trial whether the direct consequences of Dr. Bond's action ceased when Mr. Harnett was handed over to the attendants who took him away, or later when he arrived at Malling Place or when he was examined there by Dr. Adam. In any case, the consequences could not extend, in his Lordship's view, beyond 7 P.M. on Dec. 14th, 1912. It had been argued that the damages of £5000 might be justified as having been given in respect of that period, but the finding was obviously coloured by the words of Mr. Justice Lush, who, in summing-up, referred to "the whole purpose for which he was detained." The whole matter, therefore, ought to receive fresh consideration by a jury.

With reference to the case against Dr. Adam, Lord Cave pointed out that though the pleadings charged him with conspiracy and false imprisonment, no direct question as to either of these charges was left to the jury. The charge of conspiracy, if not abandoned, was negatived by the jury's answers to questions 13 and 14. The answer to 17 negatived any complicity of Dr. Adam in the detention at the Commissioners' offices, and there was no finding of false imprisonment at Malling Place. Dr. Adam must have been held liable upon the answer to question 15, as not having taken reasonable care, but the pleadings did not allege want of reasonable care, and the question only arose on the defensive plea of Dr. Adam under Section 330 of the Lunacy Act. Dr. Adam was entitled on this ground alone to judgment, but his Lordship would also examine more closely the findings of the jury and the evidence.

Firstly, was there any ground for charging Dr. Adam with conspiring with Dr. Bond to detain Mr. Harnett at Malling Place or elsewhere ? There was no evidence to support such a charge, and it was negatived by the finding of the jury. Secondly, as to false imprisonment—that is to say, retaking or detaining the plaintiff without proper authority. The medical officer was empowered by the leave of absence order to take back the patient "if his condition requires it," and this could not mean that he was to be retaken at the risk to the medical officer of having it found by a jury many years afterwards that the patient's mental condition was consistent with his remaining at large. Thirdly, there was the jury's finding as to want of reasonable care, on which stress had been laid. It had been said that the onus of proving reasonable care was on the defendant and that if he failed to prove it the retaking was void. This seemed to the Lord Chancellor to be fallacious. There might be a remedy if negligence were proved, but only by an action for negligence, not by an action for false imprisonment. He agreed, however, with the Court of Appeal in their view that there was no evidence of negligence to go to the jury and that Dr. Adam was entitled to judgment.

In conclusion, the Lord Chancellor said, public anxiety had arisen owing to the finding of the jury as to Mr. Harnett's long detention having been the result of what was done in December, 1912, when, according to the jury's view, he was sane. The full investigation of the case in the Court of Appeal and in the House of Lords had shown that no responsibility for that prolonged detention could be laid on Dr. Bond or Dr. Adam. The laws relating to lunacy provided for the protection of the public against the risk of unjustified detention, by providing precautions, and if these precautions were insufficient (but he did not say that they were), and if the lunacy laws needed alteration, that was no reason for visiting with vindictive penalties persons who had acted in good faith, and who were not responsible for any defect in the law.

Lord Dunedin and Lord Buckmaster delivered judgments to the same effect, and Lord Atkinson and Lord Sumner concurred.

As a result, Dr. Adam is to be congratulated upon the conclusion of litigation, prolonged most unfortunately for him by the conclusions arrived at in the trial before Mr. Justice Lush, and the case against Dr. Bond remains *sub judice.*

THE LAW RELATING TO CORONERS.

THE Lord Chancellor has made a welcome announcement with reference to coroners' inquests in answer to a question by Lord Darling in the House of Lords. He said that the Government proposes to introduce a Bill dealing with them in general as well as with the question raised by Lord Darling, which related to the inconvenience arising out of inquests held simultaneously with proceedings before magistrates for murder or manslaughter. This is a matter which principally concerns those charged with the administration of justice, but it would also be an advantage to busy medical men who have to give evidence not to be obliged to repeat it more often than is necessary. The desirability of substituting a new Act of Parliament for the Coroners Act of 1887 has been pointed out repeatedly in our columns. Many improvements in the law have been suggested since the Act referred to came into force. Presumably, for example, power will be given to a coroner to order a post-mortem examination in doubtful cases before deciding that an inquest should be held, and probably the system of giving certificates of the cause of death by medical men who have not seen the body will be altered. It must not be forgotten that not only was the present statute passed nearly 40 years ago, but that a departmental committee took evidence on the subject and made recommendations in 1909–10. That committee, among other matters, inquired closely into the question of inquests following deaths under anæsthetics, when the late Sir Frederic Hewitt suggested the desirability of appointing in all such cases an expert as assessor to the coroner in order that the cause of death might be determined with precision. Some special consideration of the questions arising after deaths under anæsthetics may be expected. The Chancellor, we are glad to observe, said that the Bill is now ready, and that the Government hope to introduce it before long.

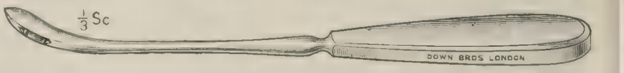
BECKETT-OVERY *v.* VAUGHAN: A SETTLEMENT.

IN this case, the hearing of which in the Chancery Division extended over five days in last March, Dr. H. Beckett-Overy sought to have his partnership with Dr. J. C. F. D. Vaughan dissolved upon grounds which included allegations as to the equipment of Dr. Vaughan for the practice in which they were engaged, and as to his conduct with regard to it, the partners having ceased to be on speaking terms. After much evidence on both sides had been given Mr. Justice Eve held that the charges put forward by the plaintiff in support of his claim for a dissolution, and denied by the defendant, had not been proved by the former; he dismissed the action, adding that nothing had transpired or was involved in his judgment that ought to affect the mind of any patient of either of the parties. Against this judgment an appeal was entered by Dr. Beckett-Overy, but when it came on for hearing Mr. Clauson, K.C., counsel on behalf of the appellant, announced that a settlement had been arrived at and asked that the appeal should be dismissed on the terms agreed. These were stated by Sir Malcolm Macnaghten, K.C., who said that his client had contested the action because he felt that there were no grounds upon which dissolution could be claimed against him. He was, however, satisfied that a dissolution should take place, and the terms arrived at accordingly were that the partnership should stand dissolved as from that date with an acknowledgment that there were no grounds on which it could be dissolved otherwise than by agreement; that Dr. Beckett-Overy should give an indemnity against the costs of the action and of the appeal; that he should repay to Dr. Vaughan the sum of £2000 paid by him for his share in the partnership, and should also pay to Dr. Vaughan £500 per annum for the next three years. The Master of the Rolls signified the assent of the Court to the settlement as stated and the appeal was dismissed accordingly. The parties are to be congratulated upon having arrived at a conclusion which saved them both from all further ventilation of their differences in public, and the successful defendant upon a result which has vindicated the position of resistance which he took up.

New Inventions.

A "SNAKE-HEADED" NEEDLE.

THIS needle is intended for the more rapid ligation of masses of omentum and mesentery in gastrectomy. It has a wide flat head, blunt-pointed, with a large eye bored sideways through the widest part of the head, and wide enough to allow any ordinary surgical needle threaded with a strong ligature to be passed through. The needle is 9 inches in length. The head is 7/16ths of an inch wide, and the shank is slightly curved on the flat 1 inch from the head. Its use is to obviate the loss of time caused by wet ligatures clinging together when drawn through soft tissue. When a ligature is withdrawn, owing to the width of the head, a gap exists between the two portions, through which the finger can at once be placed and the ligature held, cut, and tied. In use it is found best to pass the instrument unarmed through the tissues and then thread it by passing an ordinary surgical needle threaded with a ligature through the eye of the snake head. Clip forceps are put on to each end of the ligature and the surgical needle removed. The "snake head" is now drawn back, a finger slipped through the loop of ligature withdrawn, another clip forceps is applied opposite to the finger, the loop is cut near the snake head, and each portion is tied off without any risk of fouling or crossing or time lost in picking the strings asunder. The instrument has been in use in the Meath Hospital, Dublin, for many months and has been employed almost entirely in gastrectomy, although occasionally used in colectomy.



Messrs. Down Bros., 21, St. Thomas's-street, London, S.E., are the makers.

THE LANCET.

LONDON: SATURDAY, MAY 30, 1925.

RECIPROCITY OF MEDICAL PRACTICE.

THE 121st session of the General Medical Council opened on Tuesday last with the delivery of Sir DONALD MACALISTER'S presidential address. This will be found substantially in another column, and brief though it is, it presents for our consideration several quite important questions, to one of which attention should be called—namely, international reciprocity in medical practice. It has always been the ideal and policy of the General Medical Council to promote reciprocity between this country, our Overseas Dominions, and foreign nations, on the simple assumptions that the good doctor deserves recognition as such in whatever country he may elect to carry on his calling, and that geographical delimitations are at variance with the whole spirit and conduct of medical practice. But although these assumptions are true, and although it is true also that the human make-up is, to speak generally, all the world over similar, and subject to attacks all the world over which have to be repelled by analogous methods or prevented by comparable measures, still a complete free trade in medicine has not been possible, if only because the standards of the different countries cannot lead to similar methods of training. The younger nations, whether speaking literally or in regard to scientific development, have not had the opportunity of educating their followers of medicine in the same way as those nations whose development has reached higher planes; any of these nations may produce a discoverer or a pioneer, but reciprocity connotes a general or average standard among all those who practise, and cannot be established as an international routine in recognition of distinguished individual cases. There are great countries, notably the United States of America and our own Dominion of Canada, where even within their own borders the varying standards have rendered complete reciprocity difficult for the time, but scientific progress in these countries has during the last half century been so rapid that this situation must soon cease to exist. There are again countries where certain votaries of medicine have received their traditions and instructions upon principles that do not accord with what Western medicine holds to be essential, and this situation renders impossible any compact of an international character by which the practitioner along peculiarly racial lines could be bound by the general tenets. In India, however, movements have recently taken place which will tend to make it easier for the graduates of all their universities to register their degrees in the appropriate list, and Sir DONALD MACALISTER was able to tell the Council of other important directions for the establishment of medical reciprocity. Our relations in this direction with Italy were interrupted recently and to the great regret of medicine, for the generous understanding between Great Britain and Italy was of long standing. An intimation has, however, been received within this week to the effect that British and Italian medical men desiring to practise in each other's countries will again obtain the necessary facilities. In Ireland the Free State legislature has made the position for medical practitioners in Southern Ireland, for a period of one year more, at any rate, comparable to that which they would enjoy in England, as regulated by the Medical Acts. Jersey and Guernsey have brought their law into harmony with ours by a new Medical Act.

So far so good. What remains to be accomplished before anything like such international coöperation of medical effort as medical science desires and deserves can be reached is very great, but so is the growing spirit to obtain it. The part being played by medicine in the activities of the League of Nations is so practical and so beneficent that the value of international understanding upon medical questions, and of combined effort to take remedial or preventive measures, as inspired by collective wisdom, grows daily apparent. The direct route to such understanding is reciprocity of practice.

NEW ANÆSTHETICS.

THE ideal anæsthetic is still to seek. It is good, therefore, to know that there are scientific men eagerly seeking it, and the account of work in connexion with anæsthetic agents not yet widely used, which we publish on page 1126, will be of interest to all our readers. The Combined Committee set up by the Medical Research Council and the Section of Anæsthetics of the Royal Society of Medicine has sat now for a year or so, and we have reason to hope that besides the valuable work on comparatively unknown agents to which we refer above, its labours will prove fruitful also as regards the standardisation and purity of some of the more familiar anæsthetic drugs. For it is not injudicious to suspect that even to-day we may not be getting from the anæsthetics with which we are already familiar the best result that they can possibly achieve. It may be that future improvement will lie not in the substitution of other agents for nitrous oxide and for ether, but in the discovery of methods and measures by which the use of these two faithful servants may be purged of the defects which alone rob them of perfection. These are, of course, comparative impotence in the case of the former and after-effects in the case of the latter. If ether were never followed by bronchitis or sickness, and "gas" alone could always produce relaxation, we should hardly need another anæsthetic. The anæsthetics with which Dr. SHIPWAY and Prof. PEMBREY deal in their report suffer from the primary disadvantage of being gaseous. Anæsthetics which are gases at ordinary temperature and pressure are, of course, as is familiar in the case of nitrous oxide, inconvenient as regards portability and general handling. It is only the paramount excellence of "gas" in certain directions that compensates for its inconvenience and keeps it in many instances the anæsthetic of election. It does not appear that either acetylene or ethylene provides advantages over nitrous oxide that will compensate for their possession of the same defect of inconvenience. Both these gases suffer the additional disadvantages of smell and of easy inflammability. It is true that in this latter respect they are not much worse than ether, for ether, too, cannot be used near an open flame or in contact with the actual cautery. But acetylene and ethylene are rather more easily explosive than ether apart from ignition by flame, and one or two accidents that have occurred in practice show the need for extreme care when these gases are employed in conjunction with nitrous oxide. The practical question of cost is likely also to militate against wide popularity for ethylene. In many respects, however, this gas appears to a highly satisfactory anæsthetic, and it is to be hoped that the efforts of the Committee will result in bringing ethylene within easy reach of the anæsthetist. At present, except in small quantities, it can hardly be obtained unless from America. The large percentages of oxygen which it is found possible and desirable to use in conjunction with ethylene show its potency as an anæsthetic agent. It is interesting in this connexion to recall the importance attributed to small quantities of ethylene as an impurity in ether by those, as we believe mistaken, authorities who declare pure ether to be devoid of anæsthetic power. Propylene has so far been submitted to so little trial that no pronouncement can yet be made on its merits or defects. Nevertheless, it is obviously worthy of further research, and to that we have no doubt it will be submitted.

◆

ATROPHIC RHINITIS.

The causation of atrophic rhinitis, or true ozæna, still remains a matter of uncertainty and speculation. In this country the view most widely accepted is that it is the mechanical result of past inflammation which has resulted in atrophy of the mucosa, destruction of the ciliated epithelium, and degeneration of the mucous glands; the secretion consequently tends to stagnate and to dry into crusts which, by harbouring putrefactive organisms, give rise to the characteristic offensive odour. The disease is, therefore, incurable, though the worst symptoms can be ameliorated by keeping the nares free from crusts, and this view of the condition is corroborated by the ordinary results of treatment. On this theory the multitude of micro-organisms found in the nose are not the cause of the disease, but play a secondary rôle by setting up putrefaction and causing the stench. Of the numerous organisms which have been isolated from cases of ozæna several have been claimed as the specific cause, amongst others the *Bacillus mucosus* described by Löwenberg in 1894, the Klebs-Löffler and the pseudo-diphtheria bacillus, and Friedländer's bacillus, but none of these have been shown to be the true causative organism. In 1899 Perez isolated a small polymorphic cocco-bacillus from a case of ozæna, called by him the *Cocco-bacillus fœtidus ozœnæ*, which had the peculiarity that its cultures in broth constantly gave an intense sweetish odour like that of ozæna; furthermore, intravenous injection of a pure culture in puppies caused suppurative inflammation of the nasal mucosa with progressive disappearance of the bony structure, especially of the so-called anterior turbinal, while the bacillus could always be cultivated from the nasal secretion of the inoculated animals. Perez also found his organism in the nares of healthy dogs, and gave his opinion that atrophic rhinitis is an infectious disease communicable from man to man, and also that dogs are capable of infecting human beings.

The investigations of Perez have not, however, been very generally accepted, and many workers on these lines have failed to corroborate his experiments. Dr. Gustav Hofer took up the investigation in 1913; as he did not succeed in obtaining a pure culture of Perez's cocco-bacillus by cultural methods, he inoculated the mixed culture intravenously into a dog and obtained a pure culture of the organism from the resulting nasal discharge. With this he corroborated Perez's results, and further found that injection of a sterile filtrate obtained from the cultures produced the characteristic intranasal reactions. Since that time he has been a consistent advocate of the theory that the cocco-bacillus of Perez is the causative agent of atrophic rhinitis, and he has recently again published a full account of his views.[1] He finds further that the serum of 60 out of 100 typical ozæna patients gave an agglutination reaction with Perez's bacillus, although in some the organism could not be cultivated from the nose, and that no such reaction could be obtained in 40 patients without ozæna. For the last ten years he has treated ozæna by inoculations with Perez's bacillus; he naturally premises that a cure cannot be expected in advanced cases with marked degeneration of the mucosa, and does not inoculate those with advanced atrophy. Of the remaining cases he claims 8 to 10 per cent. of complete cures, 15 to 20 per cent. are refractory, and the rest are greatly improved; 15 to 45 weekly injections are required. He does not give details of the doses, nor of the age of the patients treated. Dr. Hofer writes with conviction, and a perusal of his article suggests that the subject might with advantage be investigated again in this country from his point of view.

◆

THE AMERICAN MEDICAL VISIT.

A visit to Europe on the part of 300 medical men from different parts of America will be the occasion of important scientific and social gatherings in London next week. The house of the Medical Society of London (11, Chandos-street, Cavendish-square, London, W. 1) has been placed at the disposal of the committee responsible for the arrangements, as a bureau and headquarters, and an attractive programme has been arranged. The Duke of York will welcome the guests at the Wigmore Hall, Wigmore-street, on June 2nd at 9.30 A.M., and short lectures will follow by Sir Humphry Rolleston, Sir W. Arbuthnot Lane, Sir Thomas Horder, and Dr. A. F. Hurst, the first-named acting as chairman of the session. On the morning of June 3rd, under the chairmanship of Sir John Bland-Sutton, Prof. Hugh MacLean, Mr. A. J. Walton, Colonel L. W. Harrison, Mr. W. E. Miles, Mr. T. P. Dunhill, and Dr. Strickland Goodall will give short lectures; on June 4th Dr. Gordon Holmes, Sir Walter Fletcher, Mr. James Sherren, Sir StClair Thomson, and Dr. H. C. Cameron will speak on subjects on which they are recognised as experts, while Lord Dawson of Penn will give the final lecture entitled the Speed of Life and Disease. Each lecture is timed to last for half an hour only. In the afternoons visits will be paid by small parties of 20 or 30 to various general and special hospitals where detailed programmes have been planned. The social arrangements include an evening party at the Royal Society of Medicine on June 3rd and a reception on June 5th at the Royal College of Surgeons, where, at 4 P.M., Sir John Bland-Sutton will give a short lecture on the Psychology of Animals Swallowed Alive. Various other functions are being held at the invitation of institutions and of private individuals, while the banquet at the Guildhall on June 5th, at which Dr. C. H. Mayo will preside, is likely to be a brilliant affair.

Annotations.

"Ne quid nimis."

THE PENSIONABLE AGE.

IN his speech in the House of Commons last week on the second reading of the Contributory Pensions Bill, Dr. F. E. Fremantle raised the question of the right pensionable age from the public health standpoint. To pension rigidly at 65 seems to him to be wasting money; not only so, but it means permanently throwing out of work at the age of 65 people who would be the better for working longer. The steady improvement of recent years in public health has not merely extended age as such, it has extended working age, and Dr. Fremantle sees a future in which people will live to 90, if not to 100 and 150 years of age. Whatever may be the accuracy of this prevision, it seems to be accepted by medical statisticians that, should the birth-rate continue to diminish and ultimately to approach the death-rate, there will be a much larger proportion of elderly people in the country in proportion to the working population. Many years ago Prof. Raymond Pearl remarked that a stationary population, one in which the birth-rate and death-rate balance, is necessarily a population with a relative excess of persons in the higher age-groups, and it hardly needs a great statistician to make the point. This state of affairs is likely to have important social consequences, inasmuch as we do not know if the upkeep of these elderly non-workers can be properly maintained out of the fruits of the workers' toil, whether immediately or by way of contributory pension. Dr. Fremantle would not be guided in his pensioning by the "crude mechanical age" of 65, or any other age, but would institute a test of disability to be decided by a medical board diluted with such other elements as may be required to constitute a professional technical board.

The practice of fixing a definite age at which pensions should commence appears to be general in Europe. Denmark, in a scheme of outdoor relief framed in 1891, put the pensionable age at 60 years. In Belgium and France it is 65, and in Italy a system of voluntary contributory insurance subsidised by the State provides annuities at the age of 60, when dues have been paid for the preceding 25 years. America is apparently the only country which has not adopted some form of old-age relief and has not fixed a pensionable age. The question has been studied in the light of the influence of prolonged physical activity upon the health of the manual worker. Pearl in his "Biology of Death" went so far as to suggest that the duration of life of an animal stands in inverse relation to the total amount of its metabolic activity, or, put in other words, to the work (in the sense of theoretical mechanics) that it, as a machine, does during its life. E. A. Ross, in a study of treadmill and carrying coolies, gave a very practical example of the shortening of life by exertion, and the unfortunate relationship between hard work and duration of life, shown in such extreme cases, holds in lesser degree after middle age for nearly every walk of life. Before the age of 40, according to E. L. Collis and M. Greenwood,[1] it seems to make little difference in the rate of mortality whether the occupation involves light or heavy physical labour. After 45 years of age a man shortens his life by definite amounts in proportion as he performs physically heavy labour. In the case, therefore, of lives spent in severe muscular exercise the limitation of work by a strict age-limit has a sound statistical basis. Only in occupations of a less arduous character would the postponement of the pensionable age fairly come up for consideration.

TINTED GLASSES.

IT is to be feared that tinted glasses or Crookes glasses are too often prescribed without the prescriber having any very clear idea of the exact effects which the quality of glass is calculated to have on the eyes of the patient. For this reason we welcome the publication of Sir Arnold Lawson's presidential address delivered before the Section of Ophthalmology of the Royal Society of Medicine,[1] and which we reported at the time.[2] In the first place, there is a great deal of popular misconception on the subject of ultra-violet rays. The visible spectrum extends roughly from waves of light of 700 μμ wave-length at the red end to 400 μμ wave-length at the violet end, or in some people to 380 μμ. When we come to rays of shorter wave-length, some of them are capable of chemical action which, if it were possible for them to penetrate to the retina of the eye, might be harmful to it. In the normal eye, however, it is impossible for any ultra-violet rays except those between 400 μμ and 350 μμ to penetrate so far. The cornea absorbs all waves of shorter wave-length than about 290 μμ and the crystalline lens all up to 350 μμ. Moreover, ordinary untinted glass itself is impervious to ultra-violet rays, so that in the case of wearers of spectacles they are doubly protected, and although ordinary sunlight contains ultra-violet rays as short as about 350 μμ it stands to reason that these cannot be harmful to the normal eye. It is erroneous, too, to suppose that electric incandescent lamps are stronger in ultra-violet radiation than ordinary sunlight, so that from this point of view we may say that the danger of ultra-violet radiation in the eye in ordinary life is nil. With regard to the luminous and infra-red rays, on the other hand, the case is different. The eye does not appear to possess any sufficient natural protection against an excess of these, beyond what is present in the sunlight that we ordinarily encounter, and when to excess of sunlight is added glare—the reflection from a snowfield, for instance, which, it is estimated, may be as much as 70 per cent. of the incident light, striking the eye in an unaccustomed and therefore distressing manner—the effect is such that artificial protection is called for, even for normal eyes.

What sort of protecting glasses should be prescribed? There is an interesting chart of absorption curves of various sorts of protecting glass published with Sir Arnold Lawson's paper. From this it appears that the glass which gives by far the most efficient protection against infra-red rays is that known as peacock blue, and in the opinion of Sir Arnold Lawson this is the best glass to prescribe in all cases of inflammatory disease of the retina or choroid. The colour effect of these glasses, however, is so inconvenient to the patient with healthy eyes that their use is obviously restricted. There remains the choice between different sorts of tinted glass—London smoked, amber, Fieuzal, and Crookes glass, all of various shades. From the medical point of view there is not much to choose, but Crookes A or A2 glass has this superiority, that it affords a general shade without materially disfiguring the appearance or altering colour values. They cut off all the ultra-violet rays of a shorter wave-length than 350 μμ and their use would seem to be indicated after cataract extraction, when the protection to the retina afforded by the lens no longer exists. For normal eyes, after illness or in states of lowered health, where photophobia is a symptom, Fieuzal or Crookes smoked (B or B2) glass is sometimes appreciated by the patient, but to wear tinted glasses in normal conditions is a habit not to be encouraged. In cases of neurasthenia many patients claim to have derived great benefit from the wearing of Crookes untinted glasses, but how far the element of suggestion comes in may be considered doubtful. To avert snow-blindness in the Alps London smoked, amber, or green glasses seem to be the favourite. It is said that in Shackleton's South Pole expedition even the horses had amber-tinted glasses constructed for them. A point which is apt to be overlooked, and on which Sir Arnold Lawson laid stress, is that the amount of protection afforded by any glass depends not only on its tint and composition, but also upon its thickness. When concave glasses are worn the effect must be correspondingly smaller than with a plane glass.

THE BILHARZ CENTENARY.

IN the year 1825 Theodor Bilharz was born of well-educated parents, at Sigmaringen, where his brother, A. Bilharz, a distinguished philosopher, still lives at the age of 85. As a boy Theodor had a great love of nature, and this taste was encouraged by his studies under the naturalist, Siebold. Becoming a doctor, he gave up his post of prosector at Freiburg, in Baden, when Griesinger, who had been appointed physician to the Viceroy of Egypt, invited him to come with him as his assistant in 1850. Siebold had taught him to take interest in helminthology, and in 1851 Bilharz made his first report on *Distomum hæmatobium*, the curious trematode whose males carried the females about in their gynæcophoric canals. In 1852 he declared it to be the cause of cystitis, vesical polypi, and probably of stone. In 1856 Meckel expressed the opinion that the new trematode did not belong to the genus *Distomum*, and suggested the name *Billharzia* (the mis-spelling of the author's name being no doubt unintentional): Weinland it was who, in 1858, called it *Schistosomum*. In 1852, Bilharz along with Siebold drew attention to the importance of *Ankylostoma duodenale* in the causation of anæmia, and later made researches on guinea-worm, but thereafter he devoted himself to investigations of the electrical organs of Nile fishes, and to ethnological examinations of Egyptian skulls. He contracted typhoid at Massowah, and died in Cairo in 1862. His biographer, Dr. E. Senn, describes[1] Bilharz as devoted to his friends, and unselfishly assisting all who needed his help. His importance as a pioneer in the investigation of tropical medicine is known to all.

VARIATION OF BACTERIA.

IT is now a familiar fact that from ordinary "pure" cultures of bacteria a number of strains may be separated which differ from one another in their fermentative capacities, their mode of growth, their virulence, their serological reactions, and in their other properties which are used as identifiable characteristics. The phenomena are of great interest. In the first place, the unique rapidity of multiplication of bacteria makes them material of exceptional importance in the general biological study of variation and evolution; and in the second place a proper knowledge of their possibilities in these directions lies at the bottom of an understanding of many of the larger problems of epidemiology. In two papers in the last number of the *Journal of Experimental Medicine* (vol. xli., pp. 587 and 649) Dr. H. A. Reimann of the Rockefeller Institute and Dr. H. L. Amoss of Baltimore describe observations made with type I. pneumococci. Dr. Amoss worked with a culture which had been stabilised by being passed through 189 mice; individual colonies from plate cultures showed no significant variation in virulence, nor did seven strains isolated by culture of single cocci. But if this culture was grown under somewhat unfavourable conditions—in immune serum, in dilute bile, or in somewhat acid broth—avirulent strains, mixed with normally virulent organisms, were easily obtained which differed in mode of growth and reaction to bile-solubility as well as in their action on mice. The difficulty in the interpretation of such observations has generally been that it cannot be known whether the new form was present in minimal numbers in the original culture and has become manifest only in an environment which is relatively favourable to it or whether something really fresh has arisen. Dr. Amoss can, however, give at least a partial answer to this fundamental question, for using cultures derived from the original population by the isolation of single diplococci he shows that by growth in diluted antiserum avirulent strains may be obtained which are apparently identical with those got from the ordinary culture with which he started. It seems clear therefore in this case that the avirulent strain was a new mutation and not merely an unmasked component of an originally mixed population. His attempts to reproduce a virulent strain again were unsuccessful; continued growth on favourable media and passage through mice left the avirulent strain as it was. The results throw no great light on the troublesome hygienic question whether any practical importance should be attached to, e.g., avirulent diphtheria bacilli, though as far as they go they are compatible with the sanitary experience that such brands of organisms do not matter very much. Dr. Reimann's observations gave essentially the same results; single virulent diplococci can originate avirulent strains which have never been found to revert and which to a large extent have lost their type specificity; their part in the world's economy remains to be discovered.

DRAINAGE OF THE GALL-BLADDER.

IT still appears to be an unsettled question among surgeons as to whether the gall-bladder should be removed or left in situ and drained when it is found to be inflamed at operation. Dr. Thomas S. Cullen, of the Johns Hopkins Hospital, is in the almost unique position of being able to approach the subject as a patient, for he had his gall-bladder first drained and then removed some years later, and as a surgeon who has drained the gall-bladder in nearly 300 cases. An account of the end-results of these operations by Dr. H. L. Darner forms one of the most interesting papers in the third volume of reprints recently published by Dr. Cullen.[1] Of the 290 patients who have been thus treated, in 17 the gall-bladder was gangrenous, in 104 acutely inflamed, and in 144 relatively quiescent at the time of operation, while in the remaining 25 the gall-bladder was found to be diseased when the abdomen had been opened for some other reason. When the gall-bladder was very large a portion of it was removed, but otherwise Dr. Cullen contented himself with introducing a drainage-tube accurately held in position by sutures passing through the gall-bladder wall and the rubber tube, and by additional purse-string sutures. Two "cigarette" drains were then placed just below the gall-bladder, one of which drains was removed on the first and the other on the third day, while the main drainage-tube usually came away between the tenth and the thirteenth day after operation. The abdominal wound was usually found to be healed at the end of the third or fourth week. The immediate death-rate was 10 per cent., but this was unduly high on account of the inclusion of some 17 cases in which the pre-operative condition of the patients made the result almost hopeless from the start. In following up the cases which recovered, Dr. Darner was able to obtain information about all but 14. Of the remainder, 19 were unimproved, 26 were improved but had some symptoms, while 202 had no gall-bladder symptoms at all after operation and were either alive and well or, as in the case of 34 patients, death had resulted from some other cause. Since the total number of cases was spread out over a period of 25 years, this number of deaths from other causes cannot be regarded as excessive. The paper contains a summary of nearly all the cases on which these statistics are based, and while the facts are thus fully presented, Dr. Darner has refrained from drawing any deductions other than a brief note in which he summarises the prevailing conclusions. Dr. Cullen himself admits that the question is by no means settled and he pleads for further reports as to the end-results in gall-bladder cases. A follow-up investigation of a large number of cases treated by cholecystectomy would form an interesting comparison with this exceedingly instructive paper.

LIVER EXTRACT IN HIGH BLOOD PRESSURE.

AN announcement was made at the recent annual meeting of the Ontario Medical Society to the effect that injections of a liver extract will reduce the high blood pressure of arterial disease. As yet no complete account of this work has appeared in the scientific literature, but it will be interesting to review the established scientific researches tending to support such an hypothesis. In the first place, it is a matter of common knowledge that extracts of tissues are practically always depressor in action. The effect, however, only lasts for a short time. The idea of associating the liver with chronic hypertension is by no means original. A group of investigators, about 15 years ago, paid special attention to the pharmacological properties of amines, and to their destruction in the liver. It was found that many of the amines derived from amino-acids were strongly pressor in action. Thus isobutylamine, isoamylamine and *p*-hydroxy-phenyl-ethylamine are capable of raising the blood pressure on injection (Dale and Dixon,[1] Barger and Dale[2]). It had previously been shown that these bodies could be produced from amino-acids by the action of the intestinal bacteria. The pressor effects of such amines, together with their possible production in the intestines, suggested a new cause for chronic hypertension. Thus Harvey[3] produced chronic renal and vascular sclerosis by feeding rabbits with *p*-hydroxy-phenyl-ethylamine. Clark[4] found that the oral administration of this body raised the blood pressure in man. In 1910 Ewins and Laidlaw[5] demonstrated that these amines, when perfused through a surviving liver, were detoxicated, and were converted into the corresponding oxy fatty acid derivative. Oehme,[6] in 1913, indirectly confirmed this work by proving that much larger doses of these bodies were required to kill an animal when injected into the portal vein than when the amine was administered by injection into the systemic circulation. It would appear, therefore, that the liver can detoxicate pressor bases, and the results of the further investigation promised by the University of Toronto will be awaited with interest.

WEIGHT-LIFTING.

CONTROL of weight-lifting in industry has long been a vexed question for enforcement under existing powers. Instances have again and again been quoted by inspectors of juveniles struggling with burdens weighing more than themselves; but a standard of what is reasonable, or rather not injurious, to lift has been hard to determine and harder still to present in evidence during prosecutions. The Home Office have, however, just issued draft regulations to apply to lifting heavy weights in the woollen and worsted textile industries. This draft is notable not merely as an effort to solve a difficult problem, but on account of the part played by the industries concerned. The standards adopted are those recommended to the Home Office after investigations carried out by the National Wool (and Allied) Textile Industrial Council; hence the proposed regulations represent an instance of an industry coming forward and desiring to have its practice controlled by statute. This procedure is in itself a matter of some moment. The scale of weights is here shown together with the approximate weights of those to whom it will apply :—

Person.	Maximum weight permissible to lift if body be—		Approx. mean weight of person.
	Compact or rigid.	Not reasonably compact or rigid.	
	lb.	lb.	lb.
Male	150	120	150
Female aged 18 and over	65	50	120
Male aged over 16 and under 18	65	50	125
Female aged under 18 ..	50	40	90
Male aged under 16 ..	50	40	90

If weight be any criterion of power the adult male is worst off; moreover, as he grows older he is more prone to develop hernia from weight-lifting. For the rest about half the body-weight seems to be the standard chosen if the weight to be lifted be rigid, but here the juveniles are not quite so well off, since they may lift over half their weight. Probably what is practicable, without undue interference with custom, has influenced the weights chosen, which of course represent the maximum permissible to lift and not what must be lifted. This scale, when accepted, will have administrative value, and, if it finally hastens the introduction of mechanical weight-lifting appliances, it will do good.

IN MEMORY OF SAUGMAN.

ON March 1st, 1925, Vejlefjord Sanatorium celebrated its twenty-fifth anniversary, and the occasion was marked by the publication of a collection of papers,[1] written by several of Prof. Saugman's former assistants. Half a score of these papers are of a scientific character, and they contribute not a little to the modern literature of tuberculosis. But the paper which will be read with the greatest interest by those who had the privilege of knowing Saugman is the "Appreciation," written by Dr. J. Ostenfeld, who was Saugman's chief assistant in the period 1902–1907. Here is one of the intimate touches with which Dr. Ostenfeld introduces us to the inner life at Vejlefjord :

> "It was the custom at Vejlefjord Sanatorium for the physicians to circulate different magazines among themselves, and it was the rule that the one who first got a magazine was to underline anything of special interest. It fell to my lot to get the particular number of the *Deutsche Medizinische Wochenschrift* with Forlanini's article in it, and I clearly remember how one evening I handed it over to Saugman. The next day when Saugman, as usual, joined the morning round at 7 o'clock he had been greatly impressed, and declared that now the question raised by Forlanini approached its solution."

From this date (1906) onwards Saugman contributed more than anybody else to the evolution of lung collapse treatment, and at the time of his death in February last as many as 616 had been selected for this treatment at Vejlefjord. Saugman soon found that the benefits of thoracoplastic operations were jeopardised when they were undertaken away from the hygienic influences of a sanatorium, and ultimately he decided to master the technique of chest surgery so that he could give his patients the combined benefit of surgical and sanatorium treatment. As a student he had had a penchant for surgery, but it was not till after he had turned 50 that he took up surgery seriously. But he became a very skilled surgeon, and personally operated on 91 patients. It would, perhaps, be idle to speculate what the fate of many of these patients would have been had it been necessary for them to leave the sanatorium, travel many miles, and submit to the discomforts of a thoracoplastic operation performed by a stranger in a surgical nursing home in a large town. Dr. Ostenfeld's sketch of Saugman's character portrays him as a man of strong contrasts. "His self-reliability and his humility constantly changed like storm and calm, yet so that his humility (he was always a professing Christian) was more and more apparent the older he became." He was an optimist and, as far as his optimism with regard to the character of others was concerned, he did not show great psychological insight. But his clinical optimism was unbiased and discriminating, and "his glance was penetrating in clinical matters." His commentator adds that: "His brilliant intellect was accompanied by an ingenuousness which somtimes expressed itself in quite a childlike way." But is there anyone of brilliant intellect who is not in some respects childlike?

MILK FEVER.

MILK fever or "post-partum paresis" in cows is one of those conditions which illustrate the point that the discovery of a successful empirical treatment may mislead or, worse still, kill real scientific interest in the ætiology of the disease. In 1897 Schmidt discovered that intra-mammary injection of potassium iodide was effective in curing milk fever. On the new treatment the mortality fell from about 50 per cent. to 20 per cent. and even less. Further investigation showed that the injection of many different fluids produced good results, and now mere intra-mammary insufflation is employed. There have been many hypotheses to explain this striking effect, but most of them have been very crude. In the *Veterinary Record* of March 21st, 1925, however, Prof. H. Dryerre and Prof. J. R. Greig, of Edinburgh, put forward an interesting theory. In the first place they combat Pugh's suggestion that the condition is essentially a ketosis which predisposes to a botulismus infection. They, on the other hand, hold that the disease is due to a parathyroid deficiency. This is probably so slight as to manifest itself only during the strain of pregnancy and parturition. Toxins such as guanidin then accumulate, and further, calcium metabolism is upset. At this point the animal is in a state of very unstable equilibrium, and a small amount of adrenalin liberated into the blood as a result of mild excitement is sufficient to precipitate a form of tetanic convulsions. For it has been shown by Guleke that a small dose of adrenalin will hasten the onset of tetany in an animal which has had its parathyroids removed. If, however, a large amount of adrenalin is liberated, the oxidation of the toxins is accelerated, the calcium loss is checked, and the blood pressure is raised. This, the authors suggest, is the reflex effect produced by the powerful afferent stimuli induced by intra-mammary insufflation. In this connexion it is interesting to note that cows which have an easy labour are generally those which may later develop milk fever, while those which experience a difficult labour seem to be relatively protected. In the latter case a large dose of adrenalin is presumably liberated into the blood-stream, while in the former only a small sensitising dose is produced. In view of this explanation, however, it seems strange that, while intra-mammary insufflation is sometimes inadequate to effect a cure, it is not more often just sufficient to cause a severe exacerbation. If, as the authors point out, any sympatheticotonia which exists in the condition is only relative and the supply of adrenalin is always low, then the injection of adrenalin suggests itself. We are assured that in the one case recorded in which this was done the result was encouraging. Whatever the ultimate fate of their theory these workers have at least succeeded in bringing the problem into relation with modern physiological conceptions. It is possible, too, that by this line of attack new light may be thrown not only on milk fever, but on eclampsia and similar conditions.

THE next social evening of the Royal Society of Medicine will be held at the Society's House, 1, Wimpole-street, Cavendish-square, W. 1, on Monday, June 15th, to commemorate the centenary of the birth of Charcot. At 8.30 P.M. the guests will be received by Sir StClair Thomson, the President, and at 9.30 P.M. Dr. Farquhar Buzzard, President of the Section of Neurology, will give an address on Charcot and the Centenary Celebration of his Birth.

THE BATEMAN APPEAL.

ON another page will be found the text of the reserved judgment in which the Court of Criminal Appeal gives its reasons for quashing the conviction of Dr. Percy Bateman. As already explained in THE LANCET, it has been felt that material assistance ought to be offered to Dr. Bateman to meet the legal expenses of his successful appeal and to make good the deficiency in his professional income. Accordingly the Bateman Fund has been opened and list of contributions have appeared in recent issues. We have received additional contributions as follows:—

	£	s.	d.
Already received and acknowledged ..	455	2	0
Sir James Barr	1	1	0
Dr. A. Hill Joseph	1	1	0
"Anon"	0	10	0
Dr. T. A. Hepworth	0	10	0
	458	4	0

Remittances should be forwarded to the Manager of THE LANCET, 423, Strand, W.C. 2, and made payable to the "Bateman Fund Account."

The Services.

ROYAL NAVAL VOLUNTEER RESERVE.

Temp. Surg. W. P. Elford, late R.N., to be Surg. Lt.

Proby. Surg. Sub-Lt. L. P. Spero to be Surg. Sub-Lt.

ROYAL ARMY MEDICAL CORPS.

Lt.-Col. R. N. Hunt is placed on the half-pay list on account of ill-health.

Maj. G. P. A. Bracken retires on ret. pay.

Capt. F. R. S. Shaw is secd. for serv. under the Colonial Office.

Temp. Capt. A. A. Wilson relinquishes his commn. on account of ill-health and retains the rank of Capt.

REGULAR ARMY RESERVE OF OFFICERS.

Col. H. J. M. Buist, late R.A.M.C., having attained the age limit of liability to recall, ceases to belong to the Res. of Off.

TERRITORIAL ARMY.

Maj. G. G. Marshall (late R.A.M.C., S.R.) to be Capt., and relinquishes the rank of Maj.

Capt. C. G. Irwin (late R.A.M.C., S.R.) to be Capt.

Capt. S. Summerson to command 8th (London) Sanitary Company.

ROYAL AIR FORCE.

Flight Lt. E. A. Lumley is promoted to the rank of Squadron Leader.

Flight Lts. J. F. Gallagher and James Craig (hon. Squadron Leader) relinquish their temporary commissions on ceasing to be employed and are promoted to the rank of Squadron Leader.

THE headquarters of the National Council for Combating Venereal Diseases, in future to be known as the "British Social Hygiene Council, Incorporated," have been removed from 102, Dean-street, W., to Carteret House, Carteret-street, Westminster, London, S.W. 1.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CXXIV.

THE TREATMENT OF DEMENTIA PRÆCOX.

1. THE INVESTIGATION OF THE CASE.

THE condition known as dementia præcox was first described by Kraepelin as including a large group of insane patients, mainly adolescents, who, after passing through phases of extreme mental excitement, settled down into a progressive dementia. From this early description the term derived a sinister connotation in view of the terminal dementia, and indeed, for a time, whenever a suspected case recovered the diagnosis was called in question.

Of late years, however, the conception of the disorder has radically changed, and the prognosis, although not favourable in any advanced stage of the disease, yet affords considerable hope if cases are placed under treatment sufficiently early. In out-patient clinics and in private practice it has been possible to investigate cases at a much earlier stage than that which would warrant certification as insane and detention in a mental institution. It has become clear that the original conception was derived from the study of severe and degenerative end-products of a process of which the early symptoms may be manifested by many adolescents whose mental status would not be seriously questioned. The most satisfactory view of the causation of the condition is to regard it as the failure to adaptation of the individual under the stress of circumstance. No one can have failed to realise that from the time of puberty, through adolescence, and up to adult life, great changes are in progress physiologically and psychologically as the boy grows into the man and the girl into the woman. These changes are such as to fit the individual for the detail of his life, and they should so march as to keep pace with the increasing demands for self-control and a sense of responsibility. Growth, both mental and physical, may be looked upon as the unfolding of the bud, a natural process of development; vagaries in the final form depend upon the innate characteristics and upon the pressure of environmental factors. There is a continuous modification of the organism, constituting a delicate adjustment to the natural process of growth on the one hand and to the moulding pressure of the environment on the other; a satisfactory adaptation within the personality and character is shown by the practical capacity to utilise and obtain pleasure from the opportunities which life always presents. Should circumstances be unduly hard, should innate vitality be weak, or should the original germ-plasm be abnormal, then adaptation is liable to fail. The result may be a warping of the character and personality and consequently of the subsequent life-history, but in more serious instances a breaking-up of the integrity of the organism will ensue. This is shown mentally by a schizophrenia or dementia præcox development, and the demented mind will be housed in a dilapidated physical body which exists vegetatively, and is an easy prey to infection by such organisms as those of tuberculosis or pneumonia.

If the disorder is to be successfully combated, it is of the utmost importance that early failure of adaptation or the tendency to such failure should be recognised before the establishment of degenerative changes such as those described by Mott in the endocrine organs and in the central nervous system. Yet it is an extremely difficult task to set forth in any systematic way the indications which are of value, for there is no definite organic sign, and the symptoms of early failure of adaptation are revealed only in the higher mental functions.

Suspicious Symptoms.

The spring-time of life is noted for inconsequentiality and variability of conduct and thought, and it must not be assumed that extravagance in either direction is necessarily a mark of mental deterioration, but normal biological evolution ensures that there shall be a swing back from any extreme to adjustment to practical life. Experience must be eagerly courted and as intensely avoided from time to time; disappointments must be encountered, successes must be lived down, childish sentiments must be superseded, and the domination of the parents must give way to self-conscious recognition of the ties and limitations as well as of the possibilities of adult life. Many of the episodes of youth, its emotional storms, its ideational excursions, are of the nature of psychotic crises through which the more fortunate individual passes by virtue of a firm supporting home influence and his own innate stability. Where the home influences are complex and where there is a constitutional weakness, serious results may follow. Persistence of mood is, perhaps, the most striking of the early symptoms, for it is not normal for the adolescent to be depressed, obstinate, or sulky for, more than a few days at a time, nor should he live in a constant state of lively self-satisfaction. There should likewise be a fluidity of interest; absorption in one person, one kind of play, or one line of work for several months on end portends failure of proper development. Self-absorption is natural in the girl of from 16 to 20 as is conceit in the boy of the same age, but neither state should be so persistent or so profound as to interfere with enjoyment of social intercourse and a proper consideration for the practical details of life. Self-depreciation with undue sensitiveness, persisting for any length of time, is strongly suggestive of some internal difficulty of adjustment. Religious conversions, sudden changes of disposition, or of the choice of milieu are always indicative of important subjective crises and show that the patient needs careful handling for the time.

If the stress is not relieved, grosser symptoms are encountered, such as seclusiveness or deliberate withdrawal from play or home life; frequent and violent emotional storms of anger or of tears; and obstinacy carried to the point of negativism, which is a studied and deliberate opposition to the wishes of parents or friends, persisting and involving considerable limitations on the subject. Apathy and listlessness in the presence of opportunity for enjoyment or progress are characteristic of a certain type of præcox development. Regressions to more childish ways, an indifference to dress, to appearance, and to the opinion of others, and a falling away from the intellectual standard attained are all features of importance. Temperamental inadequacies, a failure to develop the normal interests, such as dancing in the girl and sports in the boy, are the forerunners of future difficulties.

As the condition progresses more positive symptoms appear—e.g., passionate attachments between children of the same sex, ruthless antagonisms between members of the family, habits of a perverted nature, sexual or otherwise, careless behaviour fraught with danger to the self or to others, violent assaults, destructive outbreaks, and phases of intense restlessness with excitement. Finally, it becomes apparent that the patient is definitely deluded or is being distracted by hallucinatory voices, while faults of conduct, of commission or of omission, show that a serious mental change has occurred.

Physical Signs.

Physical signs are not wanting; pathologically, as Mott has demonstrated, the disorder is associated with disturbance of the endocrine system, and there are indications pointing to this morbid change, such as alterations of nutrition, excessive adiposity, or emaciation. There may be rapid overgrowth of the bony framework or a failure of physical development.

The normal distribution of hair for the age or sex may be greatly disturbed, and there are changes in the texture of the skin with a patchy hyperidrosis. In the female there is invariably a disturbance of the menstrual function; usually it is delayed and, when established, there may be marked irregularity or suppression for months or years.

As a rule the patient is brought to the doctor with a very vague history of "nervousness," of "being run down," or "not quite himself lately." The tendency is for the case to be regarded as belonging to the group of functional nervous disorders, but no label of "hysteria" or of "nervous exhaustion" should blind the practitioner to the essential mental nature of the disturbance. Having satisfied himself that he is not dealing with an organic disease, he has to make up his mind whether the failure of adaptation is to be considered due mainly to innate weakness of constitution or to pressure of circumstance. The personal and family history will indicate to some extent how far responsibility should be ascribed to the innate factor, but much caution must be exercised in accepting the statements of the relatives. It is best to get them to describe facts of the patient's history rather than to listen to their interpretations. If an aunt, for instance, is said to have had "nervous breakdowns," the practitioner should ascertain whether these entirely incapacitated her and, if so, whether she were treated at home or away; in the latter case the breakdown was probably psychotic and therefore would have considerable bearing on the prognosis of the case under consideration. The character of the parents or guardians should be carefully estimated. If they are faddists, eccentrics, or emotionally unstable individuals, then the patient will have been subjected to much harmful emotional influence, and the disturbance may be a natural outcome of such an environment and accordingly more favourable in outlook. Where the parents show sound common-sense and can be regarded as competent not to make life impossible for a developing adolescent the occurrence of a breakdown is all the more grave. In older patients, young men at college and girls away at school or engaged in full social activity, inquiries must be made as to any emotional situation which may have arisen. Where a love affair has played an important part as an exciting cause there has usually been some abnormality; either the patient has not been able to derive proper satisfaction within the bounds of convention or else these bounds have been overstepped. In cases where the difficulty in the life of the patient is one that time cannot solve the prognosis is bad. For instance, a young man, the son of a widow, had made great efforts to pass an examination which would have given him an assured position and so enabled him to support his mother. He was unsuccessful and developed an extreme depression from which he passed into an acute dementing psychosis. Here the opportunity of his life had gone, never to recur, and the situation could not be solved by time.

THOMAS BEATON, O.B.E., M.D., M.R.C.P.Lond.,
Senior Assistant Physician, Bethlem Royal Hospital.

(*To be concluded.*)

ROYAL COMMISSION ON NATIONAL HEALTH INSURANCE.—The twenty-ninth meeting of the Commission was held at the Home Office, Whitehall, on May 21st, Sir Arthur Worley in the chair. Evidence as to the organisation and procedure of medical institutions was given on behalf of the Friendly Societies Medical Alliance by Mr. S. A. Syddall and Mr. Samuel Pride; on behalf of the Friendly Societies Medical Officers' Union by Dr. D. Holmes, Dr. John H. Roberts, and Dr. A. Hamilton; and on behalf of the South Wales and Monmouthshire Alliance of Medical Aid Societies by Mr. W. Conway and Mr. Evan Pugh. Thereafter the Society of Medical Officers of Health, represented by Dr. R. A. Lyster and Dr. J. J. Buchan, gave evidence relating to extensions of medical benefit and reorganisation of the various existing public medical services. Proof copies of the oral evidence and the relative statement submitted at the meeting of May 7th are on sale at H.M. Stationery Office (3*s*.).

Special Articles.

THE MILK-SUPPLY AND ITS IMPROVEMENT.

By WILLIAM G. SAVAGE, B.Sc., M.D. LOND.,
COUNTY MEDICAL OFFICER OF HEALTH, SOMERSET.

I.—ESSENTIALS OF THE PRESENT POSITION.

(*Continued from p. 1097.*)

THE first part of the summary considered only tuberculous contamination. We have now to note:—

Other Kinds of Bacterial Milk Contamination.

The facts are so well attested that it is not necessary to discuss these in detail. Only two points demand consideration, i.e.: (1) Is there any evidence, both as regards the bacterial cleanliness of milk and specific contamination with the organisms associated with infectious diseases, that conditions are improving and less unsatisfactory than as set out in numerous books and special papers? (2) Apart from recognised specific bacteria, is it of any moment that milk is heavily contaminated? Is it possible to take the line that the only bacilli we have to trouble about are the known specific bacilli and the others are only harmless saprophytic organisms which do not matter?

As regards the first consideration, from my own experience and as judged from published reports, I consider that up to two or three years ago there was little if any improvement in the bacterial contamination of milk. Premises were slowly, in most areas very slowly, being improved, but in many districts even this was negligible, while as regards methods little or nothing in the way of a cleaner collection of milk was appreciable. On the other hand, as regards distribution risks considerable improvements were effected.

Undoubtedly, during the last few years progress has been made, in part shown as improved premises, some improvement in the adoption of cleaner methods of milking, much more in regard to the installation into the minds of the producers that their existing methods did not meet with modern requirements, and most of all in greater care and attention to the milk after it leaves the hands of the producers. Amongst these, most importance is to be attached to the sowing of the seeds of dissatisfaction with existing methods in the minds of the producer, and the recognition which he is now receiving that his difficulties are considerable and need sympathy and help to surmount them. Incidentally, it will be shown later on how very great is the leeway to be made up before the conditions in the milk trade can be passed as satisfactory. Outbreaks of infectious disease spread by milk are still fairly frequent, and the diminution, if any, is due not to greater precautions in connexion with the supervision of the milk trade itself, but to the greater thoroughness with which cases and contacts of cases are guarded from coming in contact with milk.

The second point merits consideration because the argument is often heard that bacterial contamination of milk is of no moment in itself if tubercle bacilli or other pathogenic bacilli are eliminated. In other words, dirty manure-laden milk may not be nice but it does no harm. A good many considerations suggest that this is not a sound argument. On the bacteriological side we find that the bacterial flora of dirty milk is very complex. It is composed of bacilli of the *B. coli* group, a good many non-lactose fermenters, many anaerobes like *B. welchii*, streptococci of many types, and all sorts of other bacteria. While undoubtedly the majority are of no pathogenic significance, it is impossible to speak with any certainty about the others. The streptococcus group comprises strains which are amongst the most dangerous bacteria, and our knowledge is all too inadequate to state with any assurance that some of these highly pathogenic strains are not included in the flora of ordinary dirty milk.

The susceptibility of the infant gastro-intestinal tract to bacterial invasion is a well-attested fact. That scourge of infant life—summer diarrhœa—has never had its ætiology explained, and the theory that it is not an infection with one specific type, but has a complex bacterial origin from many different types, such as streptococci or non-lactose fermenting bacilli which may be met with in contaminated milk, has at least as much to support it as any other conception as to its origin.

Numerous epidemiological studies favour the above contention, and show that the substitution of a milk reasonably free from bacteria for one heavily contaminated is directly associated with a material decrease in infant mortality-rates.[6] Apart from such non-specific or, probably more accurately, not definitely ascertained specific infections, it has to be borne in mind that the processes necessary to produce clean milk in themselves definitely reduce the likelihood of known specific bacteria gaining access to the milk. For instance, diphtheria, scarlet fever, typhoid fever, and septic sore throat are frequently spread by milk and usually from its contamination by an infected milker. Given such an infected milker, the liability of the milk to become specifically infected is immensely reduced when strict cleanliness is observed. This important point is frequently overlooked. In the same way all the tubercle bacilli in milk do not come direct from an infected udder, but many gain access from cow manure. The habits induced by the practice of clean milk production include care and attention to the milkers, and help to increase the barrier against specific infection.

The facts strongly emphasise the need to follow for milk the broad public health rule which teaches that the reduction of general bacterial contamination, although we may not be able to indite a specific agent, is usually followed by a lessening of infection from that source.

The Distributory Milk Trade and Clean Milk.

Point No. 6 requires consideration because this section of the trade is powerful and vocal, and its utterances would lead the uninitiated to imagine that from its efforts conditions are so improved that a clean pure untreated milk is being supplied. The large milk companies have materially improved the handling of milk *after* it is delivered to them. Cooling is increasingly practised, and contamination during subsequent stages is reduced by more rigid cleanliness of vessels, greater supervision over personnel, and lessened opportunities of contamination from outside sources.

On the other hand, I am unable to find evidence that they exert any controlling influence of moment over the bacterial quality of the milk which reaches their collecting depôts. Against this view it is possible to point to regulations in regard to the production of milk which some of the big companies have framed, and to the statement that inspectors are provided who exercise supervision over the conditions of milk production. Possibly these measures exert some educational influence, but my personal experience, which is very extensive, is that milk producers sending their milk to companies with these regulations are no cleaner in their methods than the average milk producer. To make the control over production more than a dead-letter, I have offered in two cases specially to report to the company producers whose methods are very unsatisfactory in order that the purchasing company can take action, but the offer has been declined.

The results of numerous bacteriological samples show that much of the milk delivered to the collecting depôts, most of which are connected with distributing companies, is grossly contaminated bacterially, and the only purification step taken is artificial—i.e., dirt extraction and pasteurisation. The milk-distributing trade could enormously improve the bacterial quality of the milk-supply within a very short period by the simple expedient of offering a higher price—it need be only a slightly high price—for milk so collected that it has a low bacterial content. I am unaware of any adoption of this attitude in this country, and although I have suggested it in several quarters it has never been seriously considered.

Chemical standards for delivery of milk to the distributor are widely adopted, because milk with a high cream content is a business asset. A low bacterial content is neither an asset to producer or distributor under present conditions unless the milk is obtained so pure that it either can be sold as graded or render all pasteurisation unnecessary. It is of importance to realise this factor since it destroys the basis of the complacent argument that the milk trade as a business proposition will as a whole improve its supply without outside compulsion. As explained under pasteurisation that trade process meets their business requirements, and there is no driving force behind any other remedy.

Pasteurisation.

Pasteurisation is a key problem in connexion with clean milk. Much of the abundant literature on the subject is loose and confusing, mainly because essentially different things are discussed as if they were identical. In connexion with milk we have to distinguish two types which for convenience may be designated *controlled* and *uncontrolled* pasteurisation.

Under the Milk (Special Designations) Order, 1923, a grade of milk "pasteurised" is recognised. It is defined as milk "retained at a temperature of not less than 145° and not more than 150° Fahrenheit for at least half an hour," and immediately cooled to a temperature of not more than 55° F. This may be called controlled pasteurisation since it is something quite definite. As such, it is possible to determine with certitude whether pathogenic bacilli will survive such treatment on the one hand, and on the other, whether the food value of the milk will be impaired.

In contra-distinction to such definite heat action the great bulk of the milk pasteurised in the country is dealt with by what may be termed uncontrolled pasteurisation. A "flash" type of pasteuriser is in general use through which the milk passes continuously, the milk being heated in its passage but only being retained at the maximum temperature for a brief moment, while for the rest of the time it is at a variable but lower temperature. There is no proper control, and I find different temperatures are used in different depôts, while it varies in the same depôt according to what the operator thinks is necessary in relation to the air temperature. The operators are untrained in the scientific principles involved, work by rule-of-thumb, and realise that when time presses they can expedite matters by passing the milk through faster. There is no guarantee that pathogenic organisms will be destroyed, or that the milk will not be damaged in its vitamin content.

Such uncontrolled pasteurisation of milk is very widely practised and in the milk depôts of Somerset the bulk of the milk is so treated summer and winter. Not infrequently the milk is again pasteurised in the large urban area to which consigned. Such milk is not labelled as pasteurised. This extensive uncontrolled pasteurisation of milk is a trade adaptation not to make milk safer but to keep it saleable and prolong its life. That is the sole reason why the considerable expense of doing it is incurred.

The advocates of pasteurisation are fond of stating that its adoption does not interfere with steps to obtain a clean milk. I have rarely heard a more absurd statement or one more in conflict with the facts. In early days when milk was produced near the milk consumers the trade managed, but when long-distance milk conveyance became a necessity and milk could not be delivered under 24 hours from the time of production, one of two things had to happen. Either the milk (at least in summer) had to be artificially preserved, or it had to be collected reasonably free from bacteria and sent cool. The former was the easier and the cheaper course, and when the addition of chemical preservatives was stopped, heat was the alternative adopted. Pasteurisation enables initially dirty milk to survive as a commercial product, and but for it clean cool milk as the only alternative would have had to be provided. In view of the practical difficulties and cost of such a pure clean milk this may have been unavoidable, and, indeed, the best plan at the time, but the fact remains that pasteurisation has come in, and remains, as a substitute for cleanliness in production and handling in this country.

---

[6] For details see Savage's Milk and the Public Health, Macmillan and Co.

At the end of 1923 the number of licences granted for the sale of "pasteurised" graded milk was 164 (shops 107, depôts 57), an insignificant proportion of the whole. A very large proportion of the milk in the country is submitted to uncontrolled pasteurisation.

The Position of the Milk Producer.

Broadly considered, milk producers handle their milk in one of three ways.

One group comprise producers who are themselves distributors. As a rule the question of souring of the milk does not arise, as most of the milk is distributed within a few hours of production to customers in the vicinity. If, however, they can earn and maintain a reputation for the supply of really clean pure milk, such a reputation is an asset of value and likely to increase their trade. This group of producers is the most sensitive to suggestions as to improving the bacterial quality of their milk.

A second group comprises producers who deliver in bulk to dairies in their immediate vicinity. If the distributing dairy is not too large, so that the contributing milks maintain a measure of identity, local reputations are of some but limited value, and diminish in importance with the amount of milk handled. Producers of this group can be induced to take a little interest in the quality of the milk they deliver.

The main group of producers deliver in bulk to milk-collecting depôts situated either in their vicinity or in large towns. Their milk is at once mixed with other milk and promptly loses its identity. When delivered and accepted the producer has no further interest in it. Provided such milk is not so acid as to be rejected, from the business point of view there is not the slightest inducement to the producers to supply a cleaner article than will be accepted. This constitutes the basic difficulty in the way of reform in production. The producer with perfectly unanswerable logic points out that what the milk inspector asks costs money, and if he spends it he will get no more for his milk; why should he do this and that when others do nothing. The much higher standard of supervision over cowsheds in urban areas than over those in rural districts is responsible for much heartburning amongst milk producers.

All acquainted with the position must feel considerable sympathy with the milk producer under the present difficult conditions. It is essential that the clean milk producer should not be penalised at the expense of the neglectful producer, and he is entitled to ask that a reasonable margin of profit should not be diminished by unreasonable demands or by requirements not universally enforced.

Losses in the Milk Trade from Contaminated Milk.

In the main the direct losses are from two sources—from milk which goes sour and is unfit for distribution, and milk which, although not yet sour, requires pasteurisation before delivery to the consumers. As regards the former, no exact figures are available, but the Second Interim Report (1917) of the Committee on the Production and Distribution of Milk gives particulars of one firm which, between April and August, 1917, received 68,000 gallons of milk (value about £4000) in a sour condition, and the Committee quote the opinion of several independent witnesses that the average percentage of London milk lost through souring was from 1 per cent. in winter to at least 2 per cent. in summer. A loss of 1 per cent. for London alone means a loss of about 900,000 gallons, which at 1*s.* 2*d.* per gallon is worth £52,500. A report[7] issued by the Ministry of Agriculture calculates a loss of at least 1 per cent. sour and in other districts quoted 1–2 per cent. loss.

As regards the cost of pasteurisation, this last report takes 10 per cent. as demanding pasteurisation to save it. It puts the cost of this at ½*d.* per gallon, or over £2000 per million gallons handled. The yearly consumption of liquid milk is about 700 million gallons, so the loss from this cause is considerable. Also 10 per cent. is a totally inadequate amount to allow for this item, as it does not include the additional milk which is pasteurised because of the fear that it may become sour. The total milk pasteurised is probably at least 50 per cent. of the whole supply (Dr. Robertson, M.O.H. of Birmingham, considers that more than 70 per cent. of the milk of our large towns is pasteurised). The pasteurisation of 350 million gallons at ½*d.* a gallon represents £727,500.

A third factor in the question of cost is that the consumption of milk is undoubtedly restricted by the fact that so much of it goes sour in the homes of the consumers. A less perishable commercial product will stimulate and increase the consumption of liquid milk. This will help the producers, since larger herds are more economical to maintain, and it gives a more certain market, while it will help the distributors, since milk is more profitable sold as liquid milk than when the excess has to be converted into milk products. These three factors together are probably sufficient to justify the ninth postulate set out above.

Adequacy of the Existing Legal Powers.

The connexion between the quality of the present supply and the inefficiency of the existing legal powers is a close and important one. It will, therefore, be discussed in some detail in the next article.

Contamination upon Consumers' Premises.

The want of care which milk receives in the homes of many of the consumers is well known and needs no detailed discussion. A minority of authorities consider the bacterial contamination from this source as the most important which milk receives, but this is not a view with which I can agree in view of the fact that any initial contamination with bacteria is multiplied many fold before it reaches the consumer, and this is only true to a limited extent for bacterial additions in the home. The want of care in the home is only in part due to negligence; a contributory factor of great importance is the very inadequate facilities in the houses of the poorer classes for food storage.

Graded Milk.

The educative value of graded milks will be discussed in a later article. As a direct contribution to the bulk of milk available to the consumer their effect is insignificant. On Dec. 31st, 1923, the producers of these milks were: Certified 55, grade A (tuberculin tested) 46, grade A 50; total 151. At the end of 1922 the total number was 63. In the county of Somerset, with over 5000 milk producers, those producing graded milks at the end of 1924 numbered only five—i.e., certified 1, grade A (tuberculin tested) 2, grade A 2.

(*To be continued.*)

RECONSTRUCTION OF ST. BARTHOLOMEW'S HOSPITAL.—In his report, as treasurer, for 1924, Lord Stanmore says that no definite information can yet be given as to the reconstruction of the hospital. It has, however, become clear that the required additional accommodation cannot be provided on the existing site; certain property in the immediate vicinity which might be utilised advantageously has therefore been acquired. The leasehold interest in Nos. 18 to 21, Charterhouse-square and Nos. 1 to 5, Charterhouse Mews (built a quarter of a century ago as an hotel) has been purchased for £51,262, and negotiations for the acquisition of the freehold and of that of No. 22, Charterhouse-square, adjoining, are in progress. With comparatively slight alteration these premises would be suitable for the housing of a large portion of the nursing staff.

[7] No. 41: Studies Concerning the Handling of Milk, 1924.

ROYAL COMMISSION ON LUNACY AND MENTAL DISORDER.

FURTHER SITTINGS.

(Continued from p. 1048.)

THE sittings of this Commission were resumed on May 22nd, Mr. H. P. Macmillan, K.C., the Chairman of the Commission, presiding.

EVIDENCE OF THE NATIONAL COUNCIL FOR MENTAL HYGIENE.

The first witnesses were Dr. Reginald Worth, Dr. E. Farquhar Buzzard, and Dr. H. Crichton-Miller, and they appeared on behalf of the National Council for Mental Hygiene. The Chairman explained that it was proposed to incorporate the Council's précis of evidence in the records, and to question the witnesses on certain points. The Council, the witnesses' précis stated, aims at bringing the treatment of mental disorder into the fold of general medicine. Whilst mental hospitals would still be necessary, there remained a large class of patients for whom at present very little provision was made—the class of early and often recoverable cases, attention to which gave the greatest hope of diminishing the incidence of more serious mental disorder, or of improving its treatment and understanding its causation. There was a world-wide trend in this direction, as shown by the formation of clinics or special departments to deal with such patients in connexion with general hospitals. Cases in which there was definite alteration of conduct, however, were not suitable for these clinics.

Patients suffering from mental disorder included, the Council say, cases in which the question of certification did not arise, such as some cases of hysteria, fears, neurasthenia, and anxiety neuroses. Secondly, those in regard to whom the question of certification arose, but who need not necessarily be certified, either because they were willing to submit to treatment, or were non-volitional—i.e., did not express objection to treatment. Thirdly, there were those for whom treatment and care were required, but as these were refused by them, obligatory treatment became necessary. It was contended that this country is lacking in adequate provision for dealing with the situation in regard to early cases. In 1923 there were 3949 suicides (2887 men and 1062 women), and it is held that these figures show a want of adaptation which is abnormal, and that the numbers could be definitely reduced by a better understanding of mental states. Incidentally, reference is made to the increasing number of cases showing mental symptoms after encephalitis lethargica, the notified cases of this kind being 1470 in 1921, and in 1924 3629. The proposed mental clinics could help materially in dealing with these cases.

Facilities for Early Cases.

The National Council circulated to 237 hospitals and infirmaries a questionnaire as to facilities for treatment of early mental cases, and 159 replies were received. In 135 institutions there was no provision for such treatment, and in 24 there was some provision, but in only five were there facilities for the in-patient treatment of early mental disorder. Many patients already attended general hospitals without realising that they were primarily suffering from mental disorder, and they continued to attend the out-patient department even when their condition was correctly diagnosed, as no means of giving them proper conditions of treatment existed, and they might be undermining the mental health of every member of their household. The department for these cases should be in charge of a suitably qualified physician. In these circumstances many cases regarded as "mental" would be found to be primarily due to physical disease. From such an arrangement, too, medical students and nurses would benefit in the matter of instruction. The Council suggest that visitation of mental patients in these clinics would not be needed, but naturally a grant of money by a public body would carry the right of supervision.

A further recommendation is that voluntary boarders should be allowed in all county and borough mental hospitals, and that the voluntary boarder system should be extended to rate-aided institutions. Medical practitioners should be allowed, they submit, to treat willing and non-volitional patients without certificates in registered nursing homes and similar institutions. They consider that wherever non-volitional cases are received some form of notification to, or supervision by, the central authority is desirable. They urge the registration of all nursing homes under the Ministry of Health; every type of abuse which might arise could then be dealt with by the ordinary process of law, and patients could have a wide choice as to where they would be treated.

Administration of Public Mental Hospitals.

The Council feel that hospital methods should be adopted in these institutions to the fullest extent, though they make this statement without implying to what degree this does not obtain already. Consultants in general medicine and surgery should be appointed for mental hospitals, and the staff of the latter should be permitted to hold corresponding positions in psychiatry at general hospitals. The Board of Control should have greater powers to enforce the adoption of such facilities where these do not exist. Practitioners should be enabled to keep in touch with their patients in mental hospitals, and to assist in the treatment where possible; they could then continue treatment when the patients returned home.

After-Care.

The Council recognise that in many cases the recurrence of mental disorder is precipitated by the patient's return to home conditions which are unsuitable; therefore such work as that being done by the After-Care Association should be in every way encouraged, and should be generously supported by the financial authority. In conclusion the Council state that such problems as illegitimacy, dependency, and the prevalence of venereal disease, prostitution, vagrancy, alcoholism, &c., are closely related to minor states of mental disorder, and are often caused by them. They consider that there is no just reason for omitting the skilled treatment of those patients on a voluntary basis, in the same way as other diseases are dealt with.

Dr. Buzzard, in answer to the Chairman's questions, said the Council was founded in 1922, and that it had a distinctive purpose in contrast with that of other bodies engaged in this class of work. One of its aims was to educate the public in regard to mental matters; and the education of the medical profession in psychiatry was recognised as deficient, though much of his practice would bring him into contact with it. Dr. Buzzard agreed, however, that students had already to become acquainted with far too many specialties. The witness did not advocate treatment in a general hospital of a case which needed restraint for any length of time.

Supervision of All Nursing Homes.

The Chairman said the suggestion that all nursing homes should be under supervision was a novel one and asked whether the witnesses thought it would be welcomed.

Dr. Buzzard replied that probably it would not be generally welcomed. The idea underlying the suggestion was the same as that concerning the treatment of mental cases in general hospitals: that where one kind of disease was dealt with another kind also could be treated.

Lord Russell asked whether the Council had considered the question of defining a nursing home in such a way that in the event of having to prosecute it would be clear, and Dr. Buzzard said that had not been gone into, but most members of his Council agreed that some kind of registration and supervision of the nursing home was desirable. The standard of these homes was capable of improvement, and it would be difficult to enlarge the liberty with which mental cases were treated in nursing homes unless all nursing homes were brought into the same category.

Dr. Worth said that if a person lost volition he should, in his view, be simply notified to the Board of Control, so that that body could know where he was. But there was no need to notify a patient who voluntarily sought treatment.

The Chairman asked who would define the voluntary patient, and the reply was that the doctor in charge was the person to do that.

The Medical Superintendent's Duties.

Dr. Worth, replying to a question by the Chairman on this matter, said he did not think the subject had been discussed by the Council. But he knew one institution in which a medical superintendent had a colleague who was administrative director, and the two were not on speaking terms. The duties were so difficult to arrange that it was necessary to have one head, who must be a medical man. This was the more necessary as the whole régime and outlook concerning the patient was a part of the treatment. The Council wished to preserve the contact between the patient and his own medical practitioner; also that there should be a closer association between mental hospitals and teaching institutions, as well as a more frequent and general resort to consultants. In his own mental hospital, which was for rate-aided patients, a retaining fee was paid to consultants. Dr. Worth dissented from the idea of considering the mental hospital as a place of last resort. Mental hospitals themselves showed a high percentage of cures. In cases requiring prolonged treatment, the patients ought to go straight away to a mental hospital.

Advisory Powers of the Board of Control.

Dr. Crichton-Miller said he favoured the Board of Control being given greater advisory powers than it at present possessed, and thought it should be possible for a general practitioner to consult the Board in regard to a case presenting difficulty. He recognised the help which the Board already gave in individual instances, but he wished that body to have wider statutory powers. A practitioner could then treat a mental case with the feeling that he was not incurring serious legal responsibility.

CHAPLAINS AND RELIGIOUS EXERCISES.

The Bishop of Chelmsford attended to speak in support of a more clear recognition of the status of chaplains in public mental hospitals. At present the appointment of these gentlemen rested with the respective medical superintendents. Attendance of patients at services held by the chaplain should be absolutely voluntary, and no question of a "test" should arise. Though the chaplain's remuneration should be based on the size of the institution, the witness would object to anything in the nature of a per capita scale. An effort was now being made to give some simple psychological instruction to candidates for ordination, in order to fit them to deal more satisfactorily with unusual and odd personalities.

Sir Humphry Rolleston said this question of the association of clergyman and medical man was a very important one, as there was sure to be some overlapping. Spiritual comfort given by the chaplain was closely related to the processes involved in psychoanalysis.

The Bishop replied that it was hoped there would be a happy partnership between the medical officer and the chaplain, just as in ordinary homes. It was felt that the appointment of chaplain should be a permanent one; in any case three years was far too short a time. In this connexion the question of superannuation was discussed. The witness did not think it wise for any man to be chaplain to a mental institution all his life; he should have a certain maximum period of service.

The Rev. W. E. Barnes, chaplain at the mental hospitals of Hanwell and Cane Hill, said he was appointed to the first named in 1920 and to Cane Hill in 1923. Formerly he was chaplain at the British Embassy Church at Petrograd for six years. Questioned as to his activities at the two mental hospitals, he said he was a friend of the patients in a different way from the doctors, and he saw them at all hours and in all circumstances. At Hanwell there were 100 communicants, at Cane Hill 60. Patients looked upon him as a definite link with the outside world, and when relatives did not take the necessary interest in patients he wrote to the former, often with good results. His relations with the medical staff were always friendly, and he frequently discussed cases with them. He had had no training for this particular kind of work until he entered upon his duties. Cases of ill-treatment of patients probably did occur, but he had never seen a case of punitive or vicious usage of a patient. He had heard, however, of two alleged cases having been investigated, in one of which the attendant concerned was dismissed.

THE LEGAL ASPECT OF LUNACY.

Sir Archibald Bodkin, K.C., attended to discuss with the Commission the legal aspect. He said he thought Part XI. of the Act might very well be re-drafted and very much condensed. When the Legislature passed the Mental Deficiency Act, 1913, it repealed the section which provided that the Order of the Commissioners in Lunacy should be accepted without further proof. Such proof was unnecessary, and in the Criminal Justice Bill now before the Commons this proving of signatures and orders of public authorities would be dispensed with, and if the Bill became an Act, this provision would extend to the Act of 1913. He agreed with the Chairman's suggestion that the subsection of Section 315 dealing with misdemeanours connected with detention and treatment of patients in unlicensed houses should be divided into two, with the appropriate penalty set out in each; or to have as many subsections as there were offences. A number of legal points were discussed by the witness in some detail.

EVIDENCE OF THE LORD CHANCELLOR'S VISITOR.

At the Monday morning session the chair was occupied by Mr. N. Micklem, K.C., and the witness was Lord Sandhurst, the Lord Chancellor's Visitor. He explained that he had been carrying out the duties of that office since 1910. There was now, he said, only one Master in Lunacy, though an Assistant Master had been appointed. Provisions concerning visitation were set out in Sections 183 to 186 of the Act. Rule 5 of the 1893 Rules enabled the Master to direct a visit in any case in which an Order appointing a receiver was pending, or in which an Order had been made under Section 116, and he appointed a visitor. Most of the witness's visits were made to private houses, the people concerned possessing some means. In the case of lunatics so found, the visitor had to pay two visits every year in every case, and the visit had reference not only to the lunatic, but also to his property and to the amount of his income and expenditure. Recommendations might then be made as to his property, such as the selling of a part of his capital, the proceeds to be devoted to his maintenance; or some of it might be more profitably invested. At present there were only 219 inquisition cases, but on the Master's books there were 6100 cases, any of whom there was the possibility of the witness being asked to visit. On the visitors' books there were 1100 cases, and 500 of these were classed as "not lawfully detained" under 116 (d), and in many of these the persons were weak-minded, proceedings having been taken because they could not manage their affairs. Three hundred of the 1100 were in institutions for the insane. The special visits paid by request in 1924–25 numbered 234. When an inquisition case was under private care, the expectation was that he would be visited four times a year for at least two years after the inquisition, as such persons had not the advantage of any other visitation. There were at present only two or three such cases. About 1850 visits were paid each year. In the case of a new patient the witness said he always paid a surprise visit, and he preferred to ascertain some particulars about him first, for a knowledge of his tastes and leanings facilitated a congenial conversation. He inquired into everything bearing on the patient's comfort and well-being. Many of the patients visited by the Chancery visitors were not certified, nor even "alleged lunatics"; they were persons who, by reason of mental infirmity arising from old age or disease, were incapable of managing their affairs, and for whom a receiver had been, or was sought to be, appointed under Section 116 of the Act of 1890. Most of such persons were suffering from some form of senile decay.

Complaints.

Fairly frequently the witness found complaints were made as to the food supplied. He had been into the kitchens and seen the food prepared, and he had been present when the patients had their meals. His view was that the meals were as good as one could expect in an institution of this character; there must be a certain amount of routine, and he would not describe the meals as dainty. If there seemed to be reasonable ground for complaint he reported the matter to the Master in Lunacy; but usually he suggested to the medical superintendent that something more might be done for the patient. Complaints about noisy, offensive, and insane patients were really a matter of classification of patients, and the complaints under this head were often well founded, the first people to admit this being the medical superintendents themselves. Basingstoke mental hospital was mentioned as a model to follow in this respect. With regard to alleged roughness and force in dealing with patients, many required some force for their control, and some were aggressive. Even senile cases were liable to periods of impulsive violence, and the witness gave an instance of this. Usually when a complaint was made, though he talked to the nurses, other patients, and the medical staff, he could not find anything tangible to work on. If he felt there was anything serious he would report it to the Master, and the Master would report it to the Commissioners. In the case of private care, a valid complaint would result in the removal of the patient to some other care.

In answer to Sir Ernest Hiley, the witness said that he had very seldom had occasion to report a case of alleged bullying or ill-treatment in the last 15 years.

The Law in Regard to Visitation.

Lord Sandhurst said the law was scarcely satisfactory with respect to visitation by the petitioner. In the petition he undertook, personally or by someone specially appointed by him, to visit the patient every six months; but there was no known way of enforcing this undertaking, and it was by no means always carried out. Neither was there any guarantee that the deputy would be a person agreeable to the patient. Usually it was desirable that the petitioner should be *en rapport* with the patient. His own experience was that the duty of visiting was rarely neglected in the humbler walks of life.

The Licensed House.

The witness said he considered that the licensed house fulfilled a most useful function, and regarded it as a misfortune that, under proper safeguards, no new licence for such could be granted. The smaller licensed house offered a degree of quiet and privacy and home-like conditions which larger institutions could not attain to; and if such accommodation was not otherwise procurable, the friends of patients were tempted to seek it in nursing homes or private houses, sometimes without certification. Two further complaints spoken of by the witness were insufficient personal attention by the medical superintendent and wrongful detention. The latter complaint was very common, but groundless, and the former was sometimes due to a personal dislike of the medical assistant. He said he had never met with a case which he considered had been wrongly certified, but he thought some patients were detained longer than was necessary.

EVIDENCE OF THE MASTER IN LUNACY.

In the afternoon the witness was the Master in Lunacy, Mr. G. M. Hildyard, K.C., who explained that when a person was certified as a lunatic he could no longer protect his property, which was therefore, to some extent, at the mercy of his relatives. It had been suggested that the latter might sometimes be tempted to get a weak-minded (but not insane) person certified so as to obtain control of his property. He could not say he had had to deal with such a case, but the possibility should be guarded against. At present a lunatic's maintenance was paid for in one of the following ways: By the guardians out of the rates (in the case of paupers); by the friends or relatives out of their own pockets; by trustees under a discretionary trust; by friends or relatives out of the lunatic's property (without authority); by friends out of the lunatic's property under authority other than that of the Lunacy Court; or by a committee or receiver out of the lunatic's property under the authority of the Lunacy Court. These the witness explained and discussed with the Commission separately; also the question of the expense of proceedings connected with the administration of lunatics' estates, the Master promising to send to the Commission some bills of costs. The Master also commented on the hardship suffered by the poor person of unsound mind by taking away his right to his old-age pension of 10*s.* weekly. If the projected new Pensions Act should pass the House, such hardships would be a good deal accentuated.

KING'S COLLEGE HOSPITAL.

FESTIVAL DINNER.

THE festival dinner of King's College Hospital was held at the Savoy Hotel on May 20th, when the Duke of Connaught presided. Covers were laid for nearly 350 guests. After the loyal toasts, the Duke of Connaught, in proposing King's College Hospital, remarked upon the financial strain which progressive scientific medicine and surgery imposed of necessity on an efficient hospital, but he was happy to report that great progress had been made in overcoming the adverse conditions that had been imposed by the war and its after-effects. Income had increased and expenditure decreased, but the two great objects the management had in view were first to pay off the debt, and secondly, to increase dependable income in order that more beds might be made available for ordinary patients. The total liabilities now, including the bank loan of £24,000, were not more than £32,000. For three years after the Armistice the hospital struggled against overwhelming difficulties. In 1919 and 1921 the expenditure exceeded the income by £38,000, and in 1920 the debt was increasing at the alarming rate of £1000 a week. Seven wards had to be closed as well as the convalescent home at Hemel Hempstead, and unfortunately the hospital was still without that very desirable adjunct. During the past two years ceaseless efforts had been made to raise money, and by the end of 1923 the debt had been reduced to £77,000. Last year Lord Hambleden with his usual generosity had cancelled his loan of £20,000 and a grant of £16,000 was made by King Edward's Hospital Fund, the grant being conditional upon 40 more beds being opened, of which 16 were to be reserved for accidents. With other help the debt had now been reduced to £24,000 and the closed wards had been reopened. Altogether 40 additional beds had been provided for general patients since the beginning of the year. In order to maintain the hospital with its additional accommodation an appeal for subscriptions of £10,000 a year had been made, and his Royal Highness had received as a result of the dinner appeal the promise of a donation of £2500 from Mr. Bernard Baron besides other subscriptions of £1000. The equipment for the use of ultra-violet rays had been installed, but the apparatus was not as powerful as they could have wished, and there was an opportunity for someone to subscribe £200 or £300 to provide a method of treatment the effect of which was often remarkable. A new source of income available since the war was the payment by ordinary patients, and out of a total income of nearly £80,000 no less than £28,600 had been received from patients themselves, while approved societies had paid another £4800. Payments by private patients were increasing, especially from the professional and tradesman class, who were attracted to the hospital because they could not afford to pay the fees of nursing homes contributed towards hospital expenses.

Lord Hambleden, in his reply, said that by strict economy and through the fall in prices the management had been able to reduce the cost of beds by something over £1 per bed per week. When 22 years ago it was decided to remove the hospital from its old site the governors expressed the hope that the income to be derived from that site would be used for the endowment of the new hospital. Unfortunately, the site was still mortgaged in the sum of £80,000 used for building the new hospital. Apart from the old site the endowments were small, amounting to no more than £5000 a year, and for years past practically the whole of that income had been used to pay the interest upon bank overdrafts. Since the appeal was started last autumn the liabilities, which were then over £70,000, had been reduced to a sum approaching £20,000, and he appealed to all who respected the voluntary hospital system to make the liabilities disappear altogether. The hospital now served a population of something like two millions of people. In conclusion, Lord Hambelden referred to the help of Messrs. Holdrons which had resulted in a donation of £1000, the help of South London schoolboys and girls, and the generous support of working men.

Lady Cheatle then proposed in felicitous terms the health of the chairman, and his Royal Highness, in replying, remarked that it was the first time the toast had been proposed by a lady, and he congratulated her upon the admirable way in which she had done it.

Lord Hambleden announced that the total sum collected for the Duke of Connaught's list before the dinner was £7305, in addition to subscriptions amounting to 37 guineas a year. The total collected at the dinner was £6025, making a total of £13,381. There was a further sum collected last autumn of £12,613, bringing that total up to £25,995. Other sums received for the reduction of debt amounted to £40,000. The sum, therefore, given in reduction of the total liabilities of the hospital was £65,995. The Stock Exchange Dramatic and Operatic Society had, he said, subscribed £105 towards the ultra-violet ray apparatus, and had promised to make up the whole sum required by Christmas.

EPSOM COLLEGE: GERALD STANLEY MEDICAL SCHOLARSHIP.—The Council of the College are about to select candidates for a Gerald Stanley Medical Scholarship, which is open to the necessitous son of a medical man. Candidates must be fully 12 years of age, and be intended for the medical profession. The scholarship is of the value of about £130 a year, and is payable in advance to the Bursar of Epsom College. It will not be continued beyond the scholar's seventeenth birthday, by which time he should have passed the matriculation examination of the University of London or its equivalent. On joining a medical school the holder of the scholarship will be required to attach himself to that of St. Bartholomew's Hospital, where, under certain conditions, a further scholarship will await him. Full particulars and forms of application can be obtained from the Secretary, at the office of the College, 49, Bedford-square, London, W.C. 1.

REX v. PERCY BATEMAN: JUDGMENT.

IN the Court of Criminal Appeal on Monday last, before the Lord Chief Justice (Lord Hewart), Mr. Justice Salter, and Mr. Justice Fraser, the following judgment was delivered by the Lord Chief Justice:—

The appellant was convicted at the Central Criminal Court before Mr. Justice Shearman of manslaughter, and was sentenced to six months' imprisonment in the Second Division. He appealed by leave against conviction and sentence. This Court, after hearing arguments of counsel, quashed the conviction and intimated that a considered judgment would be delivered at a later date.

The appellant, who is a qualified medical practitioner, was indicted for having on July 30th, 1924, unlawfully killed one Mary Ann Harding. He was called in by the midwife on the night of July 23rd, and found a very unusual and difficult presentation. He administered chloroform and attempted unsuccessfully to effect delivery by the use of instruments. No blame was imputed to the appellant on that account. He then proceeded by using his hands to perform the operation known as "version," using, of necessity, considerable force. He worked at this operation for an hour, and then delivered the child which was dead. In removing the placenta he, by mistake, removed along with it a portion of the uterus. The patient was much exhausted, and the appellant did not expect her to live. He visited her twice daily until the 28th. Although requested by the husband and the midwife to have her removed to the infirmary, he did not remove her until the 28th, on which day he wrote a letter to the superintendent that was alleged by the prosecution to be uncandid. On admission to the infirmary she was found unfit to undergo an operation. She grew gradually weaker and died on the 30th. On a post-mortem examination the bladder was found to be ruptured, the colon was crushed against the sacral promontory, there was a small rupture of the rectum, and the uterus was almost entirely gone. The charges of negligence made against the appellant were, in substance, (1) causing the internal ruptures in performing the operation of "version," (2) removing part of the uterus along with the placenta, (3) delay in sending the patient to the infirmary. For the defence it was contended that (1) and (2) were, in the difficult circumstances of the case, not inconsistent with a fair degree of care and competence, and that to have moved the patient at an earlier date would only have accelerated her death.

At the hearing of the appeal, counsel for the appellant relied mainly on the following grounds: Misdirection in law, misdirection and non-direction on the facts, and that the verdict was against the weight of the evidence.

Before we deal with the directions of the learned Judge to the jury it is desirable to consider generally the law on this subject. In expounding the law to juries on the trial of indictments for manslaughter by negligence, the Judges have often referred to the distinction between civil and criminal liability for death by negligence. The law of criminal liability for negligence is conveniently explained in that way. If A has caused the death of B by alleged negligence, then, in order to establish civil liability, the plaintiff must prove (in addition to pecuniary loss caused by the death) that A owed a duty to B to take care, that that duty was not discharged, and that such default caused the death of B. To convict A of manslaughter the prosecution must prove the three things above mentioned and must satisfy the jury, in addition, that A's negligence amounted to a crime. In the civil action, if it is proved that A fell short of the standard of reasonable care required by law, it matters not how far he fell short of that standard. The extent of his liability depends not on the degree of negligence but on the amount of damage done. In the criminal court, on the contrary, the amount and degree of negligence are the determining question. There must be *mens rea*. The difference between negligence and gross negligence is illustrated by the case of *Cashill* v. *Wright*, 6 Ellis & Blackburn 891, which was an action against an innkeeper for damages for the loss of the plaintiff's property stolen from him while he was putting up at the defendant's inn. The defendant contended that the loss had been occasioned or contributed to by the negligence of the plaintiff. At the trial the jury were directed that the defence failed unless they thought that the plaintiff had been guilty of gross negligence. On a rule for a new trial, Erle, J., delivering the considered judgment of the Court (Campbell, C.J., Wightman, Erle, and Crompton, J.J.), said: "The other question was as to the alleged misdirection in the direction to the jury that there must be gross negligence to maintain the defence. It does not appear that there was any information given to the jury as to what they were to understand by gross negligence. If they were told to understand by gross negligence the absence of that ordinary care which, under the circumstances, a prudent man ought to have taken, as seems to have been the meaning given to gross negligence in some of the modern cases cited before us, the direction as to the degree of negligence might not have been objectionable; but the legal meaning of gross negligence is greater negligence than the absence of such ordinary care. It is such a degree of negligence as excludes the loosest degree of care, and is said to amount to dolus." The rule was made absolute.

In explaining to juries the test which they should apply to determine whether the negligence, in the particular case, amounted or did not amount to a crime, the Judges have used many epithets, such as culpable, criminal, gross, wicked, clear, complete. But whatever epithet be used, and whether an epithet be used or not, in order to establish criminal liability the facts must be such that, in the opinion of the jury, the negligence of the accused went beyond a mere matter of compensation between subjects and showed such disregard for the life and safety of others as to amount to a crime against the State and conduct deserving punishment.

It remains to consider the application of this principle to cases like the present where death has been caused, in the exercise of his calling, by the alleged negligence of a person professing special knowledge and skill, and a charge of manslaughter is preferred.

The following cases may be cited as illustrating the language in which criminal negligence of this kind has been discussed and explained by Judges in modern times: Hales Pleas of the Crown, 429; *R.* v. *Williamson*, 3 Carrington & Paynes, 635; *R.* v. *Ferguson*, 1 Lewin's Criminal Cases, 181; *R.* v. *St. John Long*, 4 Carrington & Payne, 423; *R.* v. *Spiker*, 4 Carrington & Payne, 333; *R.* v. *Webb*, 1 Moody & Robinson, 405; *R.* v. *Spilling*, 2 Moody and Robinson, 107; *R.* v. *Whitehead*, 3 Carrington and Kirwan, 204; *R.* v. *Crick*, 1 Foster & Finlayson, 519; *R.* v. *Crook*, 1 Foster & Finlayson, 521; *R.* v. *Bull*, 2 Foster & Finlayson, at 202; *R.* v. *Mark and others*, 4 Foster & Finlayson, 353; *R.* v. *Noakes*, 4 Foster & Finlayson, 920; *R.* v. *Chamberlain*, 10 Cox's Criminal Cases, 486; *R.* v. *Spencer*, 10 Cox's Criminal Cases, 525; *R.* v. *Finnry*, 12 Cox's Criminal Cases, at page 626; *R.* v. *Nicholls*, 13 Cox's Criminal Cases, 76; *R.* v. *Doherty*, 16 Cox's Criminal Cases, at page 309.

The law as laid down in these cases may be thus summarised. If a person holds himself out as possessing special skill and knowledge, and he is consulted, as possessing such skill and knowledge, by or on behalf of a patient, he owes a duty to the patient to use due caution in undertaking the treatment. If he accepts the responsibility and undertakes the treatment, and the patient submits to his direction and treatment accordingly, he owes a duty to the patient to use diligence, care, knowledge, skill, and caution in administering the treatment. No contractual relation is necessary, nor is it necessary that the service be rendered for reward. It is for the Judge to direct the jury what standard to apply, and for the jury to say whether that standard has been reached. The jury should not exact the highest, or a very high, standard, nor should they be content with a very low standard. The law requires a fair and reasonable standard of care and competence. This standard must be reached in all the matters above mentioned. If the patient's death has been caused by the defendant's indolence or carelessness, it will not avail to show that he has sufficient knowledge; nor will it avail to prove that he was diligent in attendance, if the patient has been killed by his gross ignorance and unskilfulness. No further observation need be made in regard to cases where the death is alleged to have been caused by indolence or carelessness. As regards cases where incompetence is alleged, it is only necessary to say that the unqualified practitioner cannot claim to be measured by any lower standard than that which is applied to a qualified man. As regards cases of alleged recklessness, juries are likely to distinguish between the qualified and the unqualified man. There may be recklessness in undertaking the treatment and recklessness in the conduct of it. It is, no doubt, conceivable that a qualified man may be held liable for recklessly undertaking a case which he knew, or should have known, to be beyond his powers, or for making his patient the subject of reckless experiment. Such cases are likely to be rare. In the case of the quack, where the treatment has been proved to be incompetent and to have caused the patient's death, juries are not likely to hesitate in finding liability on the ground that the defendant undertook, and continued to treat, a case, involving the gravest risk to his patient, when he knew he was not competent to deal with it, or would have known if he had paid any proper regard to the life and safety of his patient.

The foregoing observations deal with civil liability. To support an indictment for manslaughter the prosecution must prove the matters necessary to establish civil liability (except pecuniary loss) and, in addition, must satisfy the jury that the negligence or incompetence of the accused went beyond a mere matter of compensation and showed such disregard for the life and safety of others as to amount to a crime against the State and conduct deserving punishment.

We have now to deal with the alleged misdirection. At the outset of the summing-up the learned Judge directed the jury as follows: "I want first of all to explain the law to you. The law is that anybody that causes the death of anybody else—it does not only apply to a doctor, it applies to motor drivers, railwaymen or signalmen, it applies to a number of people—anybody causing the death of anybody else is criminally responsible. It is equally clear law that no one is criminally responsible for what I call making a mere mistake, and it is really for the jury to draw the line between what is called making a mere mistake, an error of judgment, and doing something which is grossly and palpably wrong. I have only one objection to make to the law as put before you by counsel for the defence, that the man is bound to do the best of such skill as he has. That is not quite accurate. A medical man who practises for profit the medical profession professes skill. He does not come and say: 'I am an unskilled person'—he is engaged and professes skill. Of course, you will understand it is not for every humble man of the profession to have all that great skill of the great men in Harley-street, but, on the other hand, they are not allowed to practise medicine in this country unless they have acquired a certain amount of skill; they are bound to show a reasonable amount of skill according to the circumstances of the case, and you have to judge them on the basis that they are skilled men, but not necessarily so skilled as more skilful men in the profession; and you can only convict them criminally if in your judgment they fall below the standard of skill which is the least qualification which any doctor should have. You should only convict a doctor of causing a death by negligence if you think he did something which no reasonably skilled doctor should have done." The learned Judge then quoted the language used by Chief Justice Tindal in *R.* v. *Ferguson*, above cited, and continued: "You have got to consider if this man, in anything he did, fell below the level which you expect of a doctor—below the degree of skill which you think you have the right to expect of a doctor—by no means the extreme skill everybody knows of, but that degree of skill which you expect from a doctor who attends an accouchement and who is taken to know his business."

In the course of his review of the evidence the learned Judge referred to the law in the following passages: "That is the whole of the evidence with regard to what is called the first part of the case. It is said that this man so treated her that by his treatment he committed all these injuries, he ruptured the womb, he ruptured her bladder in pushing about, and he caused the injuries to her intestines; and in the same way it is said that when he came to pull out the placenta, instead of pulling the placenta out of the womb he caught hold of, not the placenta, but some tear or slit in the torn womb and with a tug, the expression was 'a sharp pull,' he pulled it away. It is said by the Crown that that shows that in doing this, and in pulling out the womb, he was guilty of gross negligence. It is said on behalf of the defence—and they called eminent surgeons—Well, the nurse saw nothing wrong with the way he treated her, although the force was used and necessary, and it was unfortunate. It is said there was no gross negligence, and it is for you, if you feel any doubt, to see that the prisoner gets the benefit of the doubt. But are you satisfied on that that there was gross negligence? The doctors for the defence say this: they say, 'Oh, it is quite reasonable to mistake a tear in the womb for the placenta.' That is entirely a matter for you, and it is a view not entirely accepted by the doctors called for the prosecution, although they agree in cross-examination that after all this working a portion of the womb might be torn, but a reasonably skilful man might know the difference between pulling a womb and something that might be adherent to the inside, and the prosecution call attention to the fact of the steady outflow of blood and say that in pulling out the womb he was guilty of gross negligence, and the defence say it was a very natural mistake in the circumstances of the case." . . . "The Crown first of all say there was gross negligence (and you will not find it unless you are quite satisfied of it) in pulling away the womb at all —in what he did before and in pulling it away. It s suggested by the defence, nothing of the sort, at most and at worst it was a very difficult case, and at most and at worst it was a mistake, and we say it was not negligence; it was the sort of thing that might have happened in this remarkable case." . . . "Passing away from that and summing up the first case, if you think that you are quite satisfied that it was his treatment in tearing away the womb—previous to, and up to, tearing away the womb—you will convict him; if you are not satisfied and think that there was no negligence at all, or if you have a reasonable doubt whether there was gross and culpable negligence up to that point, you will acquit him." . . . "That, substantially, is the case for the Crown on the second part of the case, and they say, substantially, he was guilty of grave, wicked neglect and culpable neglect of duty in not taking some steps to remedy what has been done by his own fault or, if you do not think it was gross negligence, they say he ought to have done something to try and save the woman's life, but he did not do anything because he wished to save his reputation." . . . "These are the historical facts. Do you think, assuming you are satisfied by the prosecution, that in pulling away the womb at all, and the acts preceding that, he was guilty of gross negligence and culpable negligence in causing her death? Then you come to the second head: was he guilty of gross or culpable negligence in accelerating this woman's death by so neglecting her from the time that he knew her uterus had been removed? If you are satisfied that the woman wanted treatment, and from the history of the case, if she had had some treatment, her life would have been prolonged, you will find him guilty; if you have any doubt about it you will find him not guilty. I will remind you of what I have said to you at the outset, that you have to be satisfied, not only that he was guilty of gross and culpable negligence, but that he caused or accelerated her death." . . . "That is the whole of the case. If you are satisfied that either in the way he delivered the child or in the way he acted afterwards he acted with gross negligence and thereby caused her death, you will find him guilty; if you are not satisfied you must acquit him on that part of the case. If you think after the womb had come away his conduct and neglect of her substantially accelerated the date of her death—if you are quite satisfied of that, you will convict him on that part of the case. If you feel any reasonable doubt on either theory you will give him the benefit of the doubt and acquit him."

If the words gross, wicked, and culpable are put aside, this summing-up amounts to a direction to the jury that they must draw the line between mistake or error of judgment on the one hand, and carelessness or incompetence on the other hand. If there was only mistake or error of judgment there is no liability, but if there was any falling short of a fair average degree of care or competence, then there is liability. Such a direction would be complete and accurate on the trial of an action for damages for negligence. It is not adequate on the trial of an indictment for manslaughter. There is, however, in the passages dealing with the evidence, a frequent use of some of the adjectives which have always been employed in explaining criminal negligence to a jury. For this reason, looking at the summing-up as a whole, this Court is of the opinion that there was no misdirection. It is, nevertheless, most desirable that in trials for manslaughter by negligence it should be impressed on the jury that the issue they have to try is not negligence or no negligence, but felony or no felony. It is desirable that, as far as possible, the explanation of criminal negligence to a jury should not be a mere question of epithets. It is, in a sense, a question of degree, and it is for the jury to draw the line, but there is a difference in kind between the negligence which gives a right to compensation and the negligence which is a crime.

The learned Judge was invited to withdraw the first and second charges of negligence from the jury on the ground that there was no evidence to support them. He declined to do so, and left all three to the jury with the instruction that they could convict on all or any of them. The jury returned a general verdict of guilty. In the opinion of this Court there was no evidence to support the first charge, based on the manner in which the accused performed the operation of version. A strong defence was presented on the third charge, and it may well be that the jury relied largely on the first and second charges. If the first had been withdrawn from them, it is impossible to say that they would certainly have convicted. For this reason the conviction could not stand.

VICTORIA HOSPITAL, SOUTHEND-ON-SEA.—In his annual report Dr. C. Grant Pugh, medical officer of health of Southend-on-Sea, states that "the most serious problem from the health point of view confronting the inhabitants is the totally inadequate provision in the way of a general hospital due to the lack of financial support given to the Victoria Hospital." It is, he points out, impossible for a hospital with 64 beds and cots to meet the needs of a population exceeding 150,000, and largely increased by summer visitors. The hospital committee find it difficult to raise enough money to maintain even the existing "grotesquely inadequate" accommodation. He points out that unless the committee of the Victoria Hospital can produce a scheme for remedying the inadequacy, either the guardians or the town council will have to do so.

SLEEPING SICKNESS IN AFRICA.

LEAGUE OF NATIONS CONFERENCE.

Sleeping sickness is a disease of great importance, both from the medical and the economic point of view. Intimately bound up with the problem it presents is that of the tsetse-fly, certain species of which act as vectors for the parasites causing the disease and which, being also the intermediate hosts of trypanosomes producing fatal disease in cattle and other domestic animals, play a most important part in retarding the development of many African colonies. If progress is to be made in combating the dangers of life in these colonies, a closer *rapprochement* between the governments of all the African territories in which sleeping sickness occurs is essential. Uniformity of records and coöperation at frontiers are among the most important administrative measures to be taken, and the powers of medical officers in affected areas must be greatly increased. The system of sanitary passports, largely in vogue throughout French Equatorial Africa and Belgian Congo, is undoubtedly a useful one and could with advantage be brought into more general operation.

The need for such measures is exemplified in the district where the South-Western part of the Bahr-el-Ghazal Province of the Anglo-Egyptian Sudan is in contact both with French and Belgian territory, and also where the Southern Sudan meets the Nile Province of Uganda. The coming and going of infected natives have occasioned local outbreaks of the disease and given cause for grave anxiety. Apart from administrative measures, the further study of the causal agents of the disease, of the means whereby it is conveyed from man to man and from wild animals to man, and of measures of prevention and of treatment is urgently required. Even drugs like "Bayer 205" and tryparsamide have not yet provided a thoroughly satisfactory therapeutic agent, possessing a maximum trypanocidal efficiency with a minimum toxicity and endowed with powers of penetrating the cerebro-spinal system and slaying trypanosomes lodged in the brain substance. But even more important is the study of immunity, and it is with arrangements for the local study of this great problem that the conference held from May 19th to 22nd at the Colonial Office, London, under the auspices of the League of Nations, has been concerned.

This conference, to consider the possibility of sending a special International Commission into Equatorial Africa for the epidemiological study of sleeping sickness, and to arrange for active coöperation of the local sanitary authorities, was the outcome of a decision of the League of Nations to institute inquiries into the scourge of sleeping sickness in Africa, as a result of which an expert committee was appointed with Dr. Andrew Balfour as chairman. The recommendations of this committee were approved by the League Council at Rome in December, 1924. The conference held last week, under the chairmanship of Mr. W. G. Ormsby-Gore, M.P., Under-Secretary of State for the Colonies, was the subsequent step in the agenda. The representatives of the various European countries were: Great Britain: (In addition to the Chairman) Dr. A. G. Bagshawe and Dr. Andrew Balfour. Belgium: Prof. Campenhout, Director of the Public Health Service of the Belgian Colonial Office. France: Prof. Gustave Martin, formerly head of the Sleeping Sickness Mission in Equatorial Africa, Prof. E. Brumpt, and Prof. Mesnil. Italy: Prof. Lanfranchi and Prof. Alessandrini. Portugal: Mr. Aires Kopke. Spain: Dr. Villa and Dr. Rocafert.

Chairman's Address.

At the opening session of the conference, Mr. Ormsby-Gore, in welcoming the delegates, said that the subject which they were called upon to examine was of the greatest importance to the whole future of tropical Africa, and not least to the British Government who had such wide responsibilities in that area. The attention of informed public opinion in England, he continued, was prominently directed to this subject by the great outbreak of sleeping sickness in Uganda about 20 years ago, when the disease caused the deaths of more than 300,000 natives, or roughly one-tenth of the total population of the Protectorate. The campaign against this outbreak necessitated the clearing of the Sese Islands of Lake Victoria and other portions of Uganda of their entire human population. The disease, though less virulent in its incidence in Uganda, was to-day, however, still existent in that country and was a present problem in many other parts of the country, as the speaker had himself seen in the course of a recent extensive tour through Northern Rhodesia, Nyasaland, Tanganyika Territory, Uganda, and Kenya. The disease was also known in the Anglo-Egyptian Sudan and also to a less extent in the British Colonies in West Africa; in fact, wherever the tsetse-fly existed there was always a danger that the disease might become epidemic in character. The report from Northern Nigeria for 1923 revealed an epidemic outbreak of a severe form of sleeping sickness in an area where its record had not been previously noted.

Turning from the British Colonies, there was probably no part of Africa to-day where the problem was more serious than in the Belgian and French Congo; very large areas were marked as sleeping sickness areas on the maps drawn up by the Expert Committee appointed by the Health Committee of the League of Nations in 1922. The French Colonies in West Africa were also affected, and one of the most important pieces of work in connexion with the problem had been effected in the Portuguese island of Principe. The disease to-day was the cause of grave anxiety in the Spanish island of Fernando Po. The speaker pointed out that the tsetse-fly occurred in belts of varying sizes practically throughout tropical Africa from Senegal on the north-west to Zululand on the south-east. Areas of special intensity were found in practically all the intervening countries. At least one-half of the total area of the mandated territory of Tanganyika was under tsetse-fly, and within its borders were found many of the principal varieties of this pest.

The Present Problem.

Mr. Ormsby-Gore then outlined the steps which had been taken to combat sleeping sickness, commencing with the International Conference held in London in 1907. Since that time, he continued, much fresh knowledge had been accumulated by workers of different nations, one of the most important discoveries being that made by Dr. Kleine, that a developmental cycle of trypanosome occurred in the tsetse-fly. Investigations of French, German, Belgian, and American scientists had been devoted towards the treatment and prevention of the disease by the use of drugs. Even so our present knowledge, said the speaker, was far from complete and further research even on these limited aspects of the problem was needed. The problem was, however, not confined to the medical treatment of the disease but, in the Chairman's words, "faced as we are by the vast extent of the infested regions, the difficulties presented by Nature and by our having to deal with the untutored and unclad natives and the prohibitive cost of introducing any large number of specially trained Europeans into tropical Africa, with its immense transport difficulties, our efforts have been often ineffective."

To free Africa from sleeping sickness, he continued, we required the services of entomologists, protozoologists, veterinary and medical scientists, and men of administrative and zoological experience. We needed not only the brain of the scientist and the work of the laboratory, but also that of the trained native administrator to apply the knowledge once it was obtained. In this country we were particularly pleased that the League of Nations had taken up this question, and we were glad to learn of the interest which was being displayed by the Rockefeller Institute and other bodies in America in this problem.

RECOMMENDATIONS OF THE CONFERENCE.

As the result of the discussions held during the session of the conference, the delegates unanimously decided to make to the Council of the League of Nations and to their respective Governments the recommendations which we give below in abstract. They read as follows :—

Administrative Measures.

In order to ascertain what zones are affected, the prevalence and distribution of tsetse-fly, the migration and movements of the populations, and the different methods of control adopted in various countries, the conference recommends :—

1. That facilities should be afforded for periodic official conferences between administrative and medical officers in charge of the campaign against sleeping sickness on both sides of the boundaries between infected countries.

2. That special agreements be concluded between lcalo administrations for rapid and regular interchange of all epidemiological intelligence and information regarding measures for control on both sides of the frontier.

3. That the recommendations of the chief of the medical service or his representative in sleeping sickness areas should be binding on the local administrations.

4. That a medical and health service be provided, including both medical officers and auxiliary staff, proportionate to the number of the population infected and the extent of the district to be inspected ; adequate administrative staffs should be available in these regions and particularly in the neighbourhood of frontiers.

5. That in sleeping sickness areas the medical officers should be given magisterial powers regarding the application of all measures in connexion with the preventive campaign ; that the system of sanitary passports for the native population in the affected areas should, where practicable, be adopted as an effective means of reducing inter-frontier traffic to a minimum, and that all information available regarding sanitary passports should be collected and the League of Nations Experts Committee requested to prepare a draft sanitary passport.

The conference wishes to emphasise more particularly the necessity of a uniform method of recording statistics relating to morbidity and mortality of sleeping sickness as well as a uniform method of preparing maps showing the prevalence of the disease, the sites of the sleeping sickness camps, sectors of prophylaxis, and the distribution of the various species of glossinæ. For this purpose the conference recommends :—

1. That the Experts Committee should study this question and present a recommendation to the Health Committee of the League of Nations for submission to the Governments concerned, including a uniform method of laboratory diagnosis.

2. That wherever practicable measures for the establishment of areas freed from populations should be taken on both sides of the frontier in order to facilitate the control of native traffic.

Special Studies and Investigations.

The conference, having examined the proposals contained in the two reports of the League of Nations Experts Committee on Sleeping Sickness in Equatorial Africa, as well as the recommendations made by the Committee during the conference, recommends that an international commission should be entrusted with the duty of investigating the problems referred to under—

(1) The existence of any human immunity against trypanosomiasis, the nature of such immunity, and the factors which determine it ; (3) the functions of wild and domestic animals as breeding-grounds for the virus ; (4) the relations between trypanosomiasis gambiensis and trypanosomiasis rhodesiensis ; (5) the testing of precipitins applied to the blood in the alimentary canal of the tsetse-fly ;

of the recommendations of the Experts Committee.

Investigations on the subject referred to above are being already carried out in the institutes of the several African countries, and the conference believes that it would be of the greatest importance if the methods of research and the technique of investigation were coördinated as between the various institutes, and that an international commission formed of representatives of the various national institutes would find valuable opportunities for scientific collaboration.

Research in Uganda.

The conference, after having considered other territories, is of opinion that Uganda and the regions in the neighbourhood of Lake Victoria represent the territory most suited for the study of the problems selected. Most valuable research work has been carried out for several years at the laboratories at Entebbe, under the competent and distinguished leadership of Dr. Lyndhurst Duke. In addition, extensive field work has been carried out by the medical services of Uganda and by the administration of the adjoining territory of Tanganyika. The conference recommends therefore :—

1. That an inquiry be made as to whether the Government of Uganda would be prepared to offer the hospitality of their laboratories at Entebbe for the work of such a Commission.

2. That the Commission be placed under the presidence and control of Dr. Duke and that it should consist of a few workers from the institutes of African Powers. The conference also believes that the collaboration of Dr. K. Kleine will be of great service to the Commission. The hospitality of the Entebbe Institute will be invited for a period of 12 months, at the end of which the Commission will present a special report to the League of Nations Experts Committee.

The Commission would begin by studying, under Dr. Duke's guidance and control, the research methods and laboratory technique at the Entebbe Institute and its field laboratories, as well as the field work and measures taken against sleeping sickness in the Protectorate of Uganda and the infected districts of Tanganyika. The field work in regard to the control of the tsetse-fly undertaken by Mr. Swynnerton in the Tanganyika territory will also be studied. The Commission will then engage in joint laboratory investigations as to the methods of work which are most suited for research into the several problems referred to it by this conference.

The conference estimates that the expenditure would amount to some £10,000, including salaries of local scientific personnel, the foreign members and laboratory assistants, as well as travelling and other general expenditure. The conference decides to ask delegates to recommend to their Governments to contribute to a common pool for meeting part of this expenditure, while it is anticipated that the Governments will continue to pay the salaries of the medical officers and other workers who take part in the work of the Commission. The conference recommends strongly that the Governments should obtain the allocation of a credit of at least £3000 in the budget of the Health Organisation of the League of Nations for 1926, and it hopes that funds may also be provided by the scientific research organisations of certain countries.

THE WORK OF THE NEW COMMISSION.

It is suggested that the Commission might conveniently meet at Entebbe at the end of December, 1925, or in January, 1926, its mandate terminating on Dec. 31st, 1926. The limitation of the period of work for the Commission at Entebbe has doubtless been deliberate. The method of study of sleeping sickness problems by means of an International Commission is quite a new idea so far as tropical Africa is concerned, and it is therefore frankly of an experimental nature. In any case the association of a number of workers of different nationalities for the elucidation of difficult and intricate problems is perhaps more likely to be profitable if their deliberations are not allowed to extend over too long a period.

The choice of Entebbe, Uganda, for the place of investigation will be welcomed, for not only is it a place where immunity can be studied with advantage but where attention can be directed to certain other problems urgently requiring solution. These are : (1) The relation of wild and domestic animals to the disease in man—in other words, the rôle they may play as reservoirs of infection, as modifying strains of human trypanosomes, as affording pabulum for the tsetse-fly. (2) The vexed question as to how *T. gambiense* stands in relation to *T. rhodesiense.* (3) The feeding habits of glossinæ as determined by the application of precipitin tests to the blood in the alimentary canal of the fly. In Uganda, moreover, sleeping sickness has apparently been mastered by the removal on a large scale of an infected population from the endemic areas and repopulation of the abandoned areas is now proceeding. Cases of human sleeping sickness may, however, be found not far away in Kavirondo, while the large scale preventive measures against the tsetse-fly, organised by Mr. Swynnerton, can be inspected by the Commission without travelling any great distance. Dr. Lyndhurst Duke, the Chairman of the Commission, is one of the foremost British workers in this field; he and his colleagues Dr. Lavier, Dr. Van Hoof, and Dr. Kleine, with a biochemist and an entomologist still to be appointed, will start organising their work as soon as those recommendations are approved by the Governments and by the Council of the League.

SALARIES IN THE PUBLIC HEALTH SERVICE.

THE British Medical Association has just issued a circular letter to local sanitary and other authorities, containing a schedule of minimum commencing salaries recommended for their adoption as a standard. The scale is the outcome of protracted effort by the Society of Medical Officers of Health with the assistance of the B.M.A., to obtain a standard of salary sufficient to attract men and women with good qualifications into the public health service and to retain their services there. Ominous signs have of late not been wanting, the letter states, that the right kind of men and women are not being attracted to the service, and that some of the most suitable officers in it are seeking ways and means of getting out. A draft scale of salaries was drawn up by a committee of the Society of M.O.H.'s in November, 1919, and was fully discussed at the annual meeting of the B.M.A. at Portsmouth in July, 1923, when the schedule was printed in full in THE LANCET (1923, ii., 187). A number of concessions have since been made, and now the Ministry of Health regards the scale as reasonable, and it has been commended as a useful guide in fixing salaries by the Association of Municipal Corporations. Agreement is not yet complete, and there are notable lacunæ, but it is a fact that the scale salary has already been offered without question by a number of authorities who had awaited the result of negotiations before filling vacancies.

Scale of Minimum Commencing Salaries for Whole-time Chief Medical Officers of Health and Medical Officers of Other Grades Recommended for Adoption as a Standard by Local Authorities.

RESIDENT MEDICAL OFFICERS.

Minimum commencing salaries per annum, £350 plus emoluments.

Definition: These are medical officers employed in hospitals, sanatoria, or other institutions without the responsibility for the work of other medical officers.

Note.—Where the appointing authority limits the appointment to a term not exceeding one year and not renewable, this salary shall not apply, nor shall it apply to officers without previous professional experience.

MEDICAL OFFICERS EMPLOYED IN DEPARTMENTS.

(Working directly under a senior medical officer.)

Minimum commencing salaries per annum, £600.

Definition: These are medical officers without responsibility for the work of other medical officers, but who shall have had at least three years' experience in the practice of their profession subsequent to obtaining a registrable qualification. One only of these years may be spent in the whole-time service of a local authority on a probationary basis at a lower salary than the minimum of £600 per annum. The salary during such probationary service shall be at the rate of not less than £500 per annum.

DEPUTY OR CHIEF ASSISTANT MEDICAL OFFICER.

(Hospitals, sanatoria, or other institutions or departments.)

Minimum commencing salaries per annum, a salary equal to 60 per cent. of salary of medical superintendent or senior medical officer in charge, but not less than the salary of a medical officer employed in a department.

SENIOR MEDICAL OFFICERS

(not being medical officers of health) in charge of services or departments—e.g., port sanitation, school medical service, tuberculosis, mental deficiency, maternity and child welfare, venereal disease, or any other similar service or department or combination thereof—and medical superintendents of hospitals, sanatoria, or other institutions.

Minimum commencing salaries per annum, £750 to £1100 according to responsibility and scope of department, regard being had to the relation of the officer's salary to that of the medical officer of health.

CHIEF MEDICAL OFFICERS OF HEALTH.

(Outside London.)

A = County boroughs, boroughs, urban and rural districts, and combined districts. B = County councils.

Population.	Minimum commencing salaries per annum.	
	A.	B.
	£	£
Not exceeding 50,000 ..	800– 900	—
,, ,, 75,000 ..	900–1000	800– 900
,, ,, 100,000 ..	1000–1100	900–1000
,, ,, 150,000 ..	1100–1200	1000–1100
,, ,, 250,000 ..	1200–1400	1100–1200
,, ,, 500,000 ..	1400–1600	1200–1400
,, ,, 750,000 ..	1600–1800	1400–1600
Exceeding 750,000 ..	1800	1600–1800

CHIEF MEDICAL OFFICERS OF HEALTH.

(Metropolitan boroughs.)

Population.	Minimum commencing salaries per annum.
	£
Not exceeding 150,000	1000–1200
,, ,, 250,000	1100–1400
Exceeding 250,000	1400–1800

Notes.

1. In cases where a local authority appoints a deputy or assistant medical officer of health the salary should bear an appropriate relation to the salary of the chief medical officer of health and the other medical officers in the service of the authority. By deputy or assistant medical officer of health is meant a medical officer duly appointed as deputy or assistant M.O.H. by the authority to assist the medical officer of health in the general administration of the health department and the carrying out of the various Acts, by-laws, orders, rules, regulations, &c., required to be, or usually administered by the medical officer of health; the title deputy or assistant medical officer of health to be limited to medical officers carrying out these general duties.

2. Where in the case of a particular appointment, whether of a medical officer of health or a senior medical officer, the local authority assigns a figure in the scale which the British Medical Association thinks inappropriate the Ministry of Health has promised to use its good offices by arranging for a joint discussion between the parties concerned at the Ministry.

3. Population means population at the latest annual report of the Registrar-General.

Conditions Applicable to All Appointments.

(*a*) The salaries to be fixed are consolidated salaries inclusive of bonus.

(*b*) There will be a periodical review of salaries by the local authorities and suitable increments of salary will be given for proved ability and satisfactory service.

(*c*) Travelling expenses and other reasonable expenses properly incurred in the performance of the duties will be paid in addition to salary.

(*d*) No existing officer is to be prejudicially affected.

PORT MEDICAL OFFICERS.

(Directly responsible to a port sanitary authority.)

Minimum commencing salary per annum, £800.

Suggested Salaries for Combined Posts, &c.

Where two or more districts combine to appoint a medical officer of health to serve under a joint committee, such medical officer of health being permitted to accept part-time duties—e.g., as tuberculosis officer, school medical officer, &c.—under the county council, the combined remuneration should be not less than the minimum commencing salary of a whole-time M.O.H., as indicated by the population of the combined areas.

Where an assistant M.O. under a county council is allowed to become a district M.O.H. for a definite proportion of his time—e.g., one half-day per week—such assistant M.O. should receive remuneration at the rate of £80 per annum for each half-day per week allocated for his duties as district M.O.H., and that his salary as assistant M.O. under the county council should be reduced by one-eleventh for each half-day per week that he is serving as district M.O.H.

The scale deals only with minimum salaries, but the view of the Association is that increment of salary should be at the rate of 5 per cent. per annum (after three years satisfactory service) rising to not less than 25 per cent. above the commencing salary. In placing existing officers in accordance with the scale, it is assumed that years of service and merit will receive recognition. The Association refuses to recognise any differentiation of salary on account of sex.

Public Health Services.

SCHOOL MEDICAL SERVICE.

STATISTICS from three school medical reports for 1924 are given in the following table :—

Name of district.	No. on roll.	Av. elem. school attendance.	No. examined in "code" groups.	Special examinations or inspections.	Percentage of children found on routine examination requiring treatment.*
Shrewsbury	4209	3756	1147	7823	7·5
Radcliffe ..	2978	2668	917	2267	24·4
Guildford ..	2998	2711	953	268	15·5

* Excluding cleanliness and dental defects.

Shrewsbury.

Dr. Gordon Smith, in his report to the borough council of Shrewsbury, points out the insanitary condition of many of the schools, some of which have been condemned by H.M. inspector. The educational, no less than the physical, well-being of children is so dependent on good environmental conditions that the quick remedying of insanitary conditions in all schools would be a sound investment on the part of all local educational authorities. The small percentage of defects found (7·5) is explained as being due to the work of the child welfare scheme being well carried out and by the existence of an efficient school clinic, where the treatment is carried out by the school medical officer in addition to his duties as M.O.H. Dr. Smith does not disguise the considerable difficulty he has in carrying out unassisted his ever-increasing duties.

A feature of the report is the number of statistical tables showing the incidence of defects amongst the various age-groups. In the malnutrition table it is seen that 7·4 per cent. of the 8-year old children are below normal as against 12·5 per cent. of the entrants and 17·8 per cent. of the 12-year olds. These figures indicate rather a high percentage of poor nutrition. The lessened incidence in the 8-year old group is interesting as it is at variance with most findings at this age. "Many of these badly nourished children are seen at the clinic and are difficult to deal with. Some are obviously underfed. It would be a great advantage if suitable cases could be supplied with a daily ration of milk or cod-liver oil. . . . Many of the teachers would be willing to issue the milk at schools. . . ." The local education authority would avoid reproach by putting into operation the Education (Provision of Meals) Acts, 1906–14.

Dental defects were found in 64·3 per cent. of children at routine medical inspections while only 29·8 per cent. were found by the school dentist at his inspections—from these figures it would appear that the dentist picks out only the worst cases for treatment. The percentage of parents present at routine examinations (50 per cent.) is not high and would indicate rather a lack of interest in the good work.

Radcliffe.

Dr. J. M. Gibson's well-written report presents many points of interest and much care has been taken in its compilation. The various public health services are now coördinated with the school medical service, and the health visitor supervises and keeps records of debilitated children under school age and when necessary treatment is given at the school clinic. The difficulty of efficient school ventilation is commented on and the importance of fresh moving air is emphasised, as is the necessity for well-lighted, bright, and clean rooms. The figures for uncleanliness of the head and body show a steady improvement from 590 in 1921 to 185 in 1924. The percentage of visual defects in not high—4·2 per cent. were referred for refraction, and it is satisfactory to note that 101 cases out of 107 recommended for glasses obtained them.

Tables are given showing the monthly incidence of scarlet fever and diphtheria in the various schools and one showing the weekly incidence and school distribution of measles during September–December, 1924. In his pertinent observations on infectious disease, Dr. Gibson concludes that, in such a district as Radcliffe, school closure has no effect in preventing the spread of infection; on the contrary, measles can be more effectively controlled and the children's interests better safeguarded by keeping the schools open. He rightly says that the help of the teachers is essential, and is readily given, for the early recognition and consequent isolation of suspicious cases, especially as parents are not acquainted with the early signs of the disease. There are no facilities for open-air education in the district, but in many places open-air classes are held in elementary schools with excellent results.

In a special inquiry it was found that 12 children had a mental retardation of two to three years, while 27 had a mental age (Binet-Simon) of more than three years lower than their respective chronological years. There would thus appear to be sufficient candidates for a special school; pending the formation of such a school many of these children might benefit from instruction in special backward classes in the elementary schools.

Dr. Gibson records his thanks for the cordial and valued coöperation of the local medical practitioners with the school medical staff.

Guildford.

In the relatively small area of the borough of Guildford, Dr. R. W. C. Pierce, the S.M.O., is fortunate in having Dr. A. Pimm as medical inspector to assist him in his school work. From the above table it will be seen that there were comparatively few special examinations (40) and re-inspections (228). Special cases are usually referred by parents, teachers, nurses, or school attendance officers, and constitute an important feature of school work, as most of the children so referred are either suffering, or suspected to be suffering, from some definite illness, and the medical examination of such children gives confidence and encouragement to the parents. One such case successfully treated often does more good than the examining of many routine healthy children. No provision exists for open-air education, but teachers are urged to hold playground classes for debilitated anæmic children.

The medical inspector apparently only recommends for treatment the very worst cases of dental caries, as only 61 were so referred out of a total of 1221 examined. Whereas the dentist referred 1040 out of a total of 1365 inspected, and of those referred for treatment by the dentist 688 obtained it. The number of exceptional children is too small to make the provision of special schools readily feasible. Five such children are maintained in outside institutions, but some special classes might be organised for the education of 18 mentally deficient children who are at present in elementary schools.

The school nurses seem to be hard-worked and a great deal of their time is spent in general welfare work which has the incidental advantage of gaining for them and their work the sympathy of the parents. Mention is made of valuable voluntary workers, and it is hoped that their numbers will be increased or some other help obtained, for it is scarcely desirable that such work should fall upon the teachers though their interest is essential to the success of the medical work.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED MAY 16TH, 1925.

Notifications.—The following cases of infectious disease were notified during the week, namely:—Small-pox, 157; scarlet fever, 1702; diphtheria, 807; enteric fever, 56; pneumonia, 963; puerperal fever, 59; cerebro-spinal fever, 9; acute poliomyelitis, 4; acute polioencephalitis, 1; encephalitis lethargica, 70; dysentery, 4; ophthalmia neonatorum, 106. There were no cases of cholera, plague, or typhus fever notified during the week. The number of small-pox cases showed a decrease of 5 from the number for the preceding week.

Deaths.—In the aggregate of great towns, including London, there were 3 deaths from enteric fever, 83 from measles, 12 from scarlet fever, 88 from whooping-cough, 31 from diphtheria, and 58 from influenza, as compared with 68, 100, 139, and 162 in the four preceding weeks. In London itself the deaths from influenza numbered 4, from whooping-cough 21, and from diphtheria 4.

Obituary.

NORMAN VEITCH CUNNINGHAM LOTHIAN, *M.C.*, M.B., CH.B. GLASG., D.P.H., D.T.M. & H. CAMB.

WHILE travelling from Beit Mari to Beirut in Syria on May 22nd Dr. Norman V. C. Lothian, epidemiologist of the Health Section of the League of Nations and member of the League of Nations Malaria Committee, was killed as the result of a motor-car accident, which also caused the death of two other members of the committee, Dr. Samuel Darling, U.S.A., and Mlle. Besson, France.

Dr. Lothian graduated in Arts, Science, and Medicine at the University of Glasgow, obtaining the M.B., Ch.B. in 1912. He continued his studies in London and New York, later in 1919 gaining the Cambridge Diploma of Public Health and the Diploma of Tropical Medicine and Hygiene. On qualifying in medicine he joined the Royal Army Medical Corps, where he specialised in hygiene, attaining the rank of major. His many papers in the *Journal of the Royal Army Medical Corps* bear evidence to his ability and to the readiness of his seniors to profit by it. Thus he was asked to prepare "a historical inquiry into the load carried by the soldier of various periods,"[1] when he showed that the soldier should not be asked to carry more than 33 per cent. of his weight; the mule carries 32 and the horse 28 per cent. only, and weights over 33 per cent. destroy the marching power of the soldier and lose battles. Other papers include: Purification of Water on Field Service (Trans. Brussels Internat. Conf. of Military Surgeons), Note on the Rate of Marching and the Expenditure of Energy in Man (with Cathcart and Greenwood), *Journal R.A.M.C.*, 1920; the Activated Sludge Method of Sewage Disposal, ibid., 1921; Chlorination of Water in Galvanised Iron Vessels (with A. R. Ward), ibid., 1922.

For the past two years he had been associated with the League of Nations, and from the British member of the Health Committee of the League we have received the following appreciation: "The tragic death of Dr. Norman Lothian will come as a great shock to the little band of medical officers of different nationalities who form the Health Section of the Secretariat of the League of Nations at Geneva. Dr. L. Rajchman and his colleagues had gained some two years' experience of Dr. Lothian's great capacity and untiring industry. These qualities, combined with a most attractive personality, had gained for him the highest regard and respect, not only of his colleagues on the Secretariat, but also in special measure of the members of the Health Committee and the public health officers of the many countries which it was his duty to visit. Dr. Lothian travelled extensively with the special missions of the League, particularly that on malaria, of which he was secretary, and for which he had quite recently drafted some invaluable reports. He accompanied the "interchange courses" of foreign public health officers which are now a regular part of the programme of the Health Organisation at Geneva. Wherever he went he showed the same high ideal of duty and industry; he was ready for every need or difficulty, and his modesty and charm endeared him to all. With this aptitude and with the quite exceptional experience of sanitary administrative measures and of the persons responsible for them in different countries, a great future had seemed to be before him in the sphere of international public health."

JOHN THOMAS GRAHAM, M.D., C.M. GLASG., M.R.C.S. ENG.

Dr. John T. Graham, who for 35 years was medical officer of health for Perthshire, died at his residence in Perth on May 20th, after a short and sudden illness. A son of the Rev. Dr. Robert Graham, he was born at Abernyte in the Carse of Gowrie in 1853. He studied medicine at Glasgow University and at St. Bartholomew's Hospital, London, qualifying M.B., C.M. Glasg. in 1874 and M.R.C.S. Eng. the following year. In 1878 he obtained the M.D. of Glasgow. Dr. Graham began his professional career in general practice in Perth, and in 1890 was appointed first medical officer of health for the county on the passing of the County Councils Act. He was also chief tuberculosis officer for Perthshire.

Dr. Graham was well known throughout the county, where his abilities as a public health administrator, together with the tact he always showed in carrying out his duties, won for him the confidence and respect of fellow medical practitioners and public officials. Dr. Graham showed a keen interest in public affairs, and at the time of his death was chairman of the Perth Sick Poor Nursing Association. Apart from medical and public work, he devoted much of his spare time to the study of mechanics and electricity.

An old friend and colleague, "R.S.," sends us the following appreciation: "When Dr. Graham began his professional life in the late seventies specialism was only in its infancy, but as a member of the visiting staff of the Perth Royal Infirmary he had opportunities of developing his surgical instincts, and his colleagues learnt to trust both his judgment and manual dexterity. He was a good operator and would probably have achieved distinction had not circumstances diverted his talents in another direction. Abandoning general practice, he became full-time medical officer of health, although he relinquished with regret the surgical and obstetrical work in which he had established an enviable record. The change was probably a wise one, since more than one severe illness had somewhat impaired a powerful physique. To his new duties he brought the same devotion and good sense displayed in his former sphere. So passes away one of the old school, a fine type of the practitioner. As a friend and counsellor he will be greatly missed."

Dr. Graham is survived by his widow and two sons, one of whom is in the medical profession.

THE trainees and families at the Devon and Cornwall Ex-Service (Tuberculosis) Colony, Plymouth, presented a gold-mounted fountain pen to Dr. F. G. Bushnell on May 21st on the severance of his association with Efford Camp.

---

[1] Report on Health of the Army for 1921, p. 14.

THE GENERAL MEDICAL COUNCIL.

SUMMER SESSION.

President's Address.

The summer session of the General Medical Council was opened on May 26th, when Sir **Donald MacAlister**, the President, delivered his address.

He began by paying a tribute to the late Sir Clifford Allbutt as a leader in many departments of medicine, pre-eminent in his mastery alike of its literature, its science, and its practice, and by offering the Council's good wishes to Sir Humphry Rolleston, his successor in the Cambridge chair. He also recalled the valuable work, as inspector of qualifying examinations in medicine, of the late Dr. H. H. Tooth, whose recent death left a memory of assiduous and unselfish labour for worthy ends. They would, he said, miss the presence of Mr. E. B. Turner, whose vigorous fluency of address and intimate acquaintance with divers sides of medical life and practice had often given colour to grey debates. He welcomed his successor in the English representation, Dr. H. B. Brackenbury, an experienced medical statesman of approved loyalty and wisdom.

Medical Education and Registration in the Irish Free State.

In February last, Sir Donald MacAlister continued, an Act was passed by the Free State Legislature, which in effect provides that in Southern Ireland the Council's constitution and powers, and the powers and responsibilities of its universities and corporations, shall, so long as the Act is operative, continue to be regulated by the Medical Acts, as they were regulated before the Irish Free State was established. It is, of course, open to the Free State, if it thinks fit, to renew the Act for a further period before its expiry in February, 1926. No similar Act has been passed relating to the dental profession, and accordingly the jurisdiction of the Council and of the Dental Board over dentists in the Free State has come to an end. I have not learned that any local regulation of the dental profession has been established in its stead. It still remains, for the complete validation of the Council's powers, and of its acts in the interim period, that complementary legislation should be adopted in this country. We are informed by the Privy Council that the necessary Bill has been drafted and will shortly be laid before Parliament.

Medical Reciprocity with Italy.

The question of re-establishing reciprocity, interrupted by recent legislation to the detriment of British medical men desirous of practising in that country, has been the subject of much correspondence during the recess. At one time it appeared that, owing to the unexplained delay of the Italian authorities in concluding the "special agreement" required by the new law, it would be necessary to rescind the Order in Council which applies the Medical Act of 1886 to Italy. But an intimation by the Executive Committee to that effect seems to have had a useful result; for we have received a telegram sent by H.M. Ambassador at Rome, stating that the agreement with Italy was signed on Thursday last, May 21st, and that the signed text was on its way to London.

Dominion Reciprocity.

The Province of Saskatchewan, whose recent enactment has made it impossible for practitioners on the British Register to obtain provincial registration, while Saskatchewan practitioners still retain the privilege of registration upon the Colonial List and so of practising in this country and in British possessions overseas, has sent a reply expressing the views of its medical council. It is to the effect that there is no desire to retain British reciprocity if that involves inter-provincial reciprocity, and reciprocity with countries other than Great Britain. The Executive Committee have therefore felt constrained to represent to the Lord President of the Council that the conditions under which the Order in Council of 1915 was made have ceased to be observed by Saskatchewan, and that accordingly it is just and expedient that the Order should be forthwith rescinded.

Correspondence with the Province of New Brunswick, where a somewhat similar question has been raised, appears to indicate that inter-provincial differences and misunderstandings are responsible for the "current discontents." The local authorities, however, plead for further consideration of the question, and deprecate the rescission of the reciprocity Order until that consideration has been given. The Executive Committee have no desire to precipitate matters with the Province, and have given instructions for a reply to the Provincial authorities, which shall make it clear that we agree in our desire that reciprocity with the Dominion as a whole should take the place of the present agreements with the provinces separately, so soon as the provisions of the Canadian laws render this practicable. Dominion reciprocity has long been the aim of the Council. It would bring with it a greater uniformity of provincial standards, and the elimination of local difficulties between neighbouring provinces, with which the Council cannot effectively concern itself.

India.—Channel Islands.

In India the progress towards a satisfactory system of medical instruction and examination in the Universities of Bombay and Lucknow, as reported by the official inspector, has justified the Executive Committee in continuing the conditional recognition of their degrees until June 30th, 1926. The Committee have not yet found any grounds for reconsidering the position of the University of Calcutta, whose degrees are not now registrable in the Colonial List.

Those ancient domains of the Crown, Jersey and Guernsey, have, by a new Medical Act, dated March 10th, 1925, brought their law into harmony with that of the adjacent islands of Great Britain and Ireland by requiring that practitioners, to be legally qualified, must be registered in the Medical Register. They have, moreover, set these islands a good example by prohibiting, under penalty, any person who is not legally qualified from practising medicine or surgery.

Pharmacopœial Conference.

The International Conference on the Unification of Pharmacopœial Formulæ is to be held in Brussels in September. The Government will be represented by four delegates, of whom our colleague, Sir Nestor Tirard, is one. I learn with gratification that he has been asked by the Government to act as chairman of the British Delegation. The Government has adopted the reserves regarding the subjects to be discussed, and the conclusions that may be reached, which were suggested by the Pharmacopœia Committee.

Dental Examinations.

The Dental Education and Examination Committee will present a report on the inspection by Mr. J. Howard Mummery, C.B.E., of the qualifying examinations in dentistry and dental surgery held during the past two years. It is good to learn that all the examinations have been reported "sufficient." In certain instances the inspector has made suggestions towards improvement in matters of detail. These have been communicated to the several examining bodies, and it is reported by the inspector that they have been accepted, and in some cases are already in operation.

Number of Medical Students.

This time last year, Sir Donald MacAlister continued, I commented on the fall in the number of medical students registered—namely, from 1833 in 1922 to 545 in 1923. The sudden decline I thought to be more apparent than real, attributing it to the recent introduction of a pre-registration test in elementary physics and chemistry. This test many students would not pass, and so could not register, until the end of their first term, at least, after leaving the secondary schools. The explanation would seem to be sound, for in 1924 the registrations were nearly doubled, reaching 1043 by the end of the year. As the working of the new regulation is better understood in the schools, and as the general and scientific education of intending medical students is brought up to the higher standard now required, there is little doubt that the number of qualified entrants on the medical curriculum will approach the pre-war figure of 1300 or 1400, a number sufficient to supply the needs of the country for qualified practitioners.

The total number of new registrations in the Home List of the Medical Register in 1924 was about 2566, or about 330 more than in the previous year. This increase reflects the very large entry of students in the years immediately following the close of the war. The steady decrease in that entry since 1919 will correspondingly reduce the additions to the ranks of the profession, and it is highly probable that in three or four years the annual increment to the Register will fall to pre-war proportions.

Finance.

As the income of the General and Branch Councils is mainly dependent on registration fees, it is not surprising that the receipts for the year have been considerably augmented. The expenditure has remained nearly stationary, and there is therefore a surplus on the total account of more than £7000. The treasurers have thus been able to provide for exceptional outlays on elections, inspections, and visitations, fresh issues of the British Pharmacopœia, the possible extension of the lease of the Council's buildings, the establishment of an orderly system of pensions for the office staff, &c., and also to lay up modest reserves for other irregularly recurring charges, without drawing on accumulated capital. These wise precautions will serve to stabilise the Council's finances for some time to come, even if the second half of the present decade is less prosperous than the first. We have no margin for lavish expenditure; but the careful husbandry of the Finance Committee will enable us to meet without hardship any expense that is really necessary for efficiency.

A Presidential Gift.

Before I conclude, said Sir Donald MacAlister, may I offer for the acceptance of the Council the decorated window, designed by Dr. Anning Bell, R.A., which, with the kind assent of the Executive Committee, I have ventured to instal temporarily behind this chair? While, from the material side, it may help to brighten the sombre tints of the urban landscape over the way, and shield you from the rare importunities of the western sun, I hope that from the symbolic side it may help to preserve the remembrance of those who have been honoured by your confidence as Presidents of the Council, including the latest and longest borne with, your devoted and grateful servant.

The adoption of the address was moved by Sir Isambard Owen, seconded by Sir Norman Walker, and was carried with acclamation. The Council then proceeded to the consideration of three penal cases reported by the Dental Board of the United Kingdom, and thereafter received reports from the Dental Education and Examination Committee, submitted by Sir James Hodsdon. After the election of Executive and Dental Committees, and of the Penal Cases Committee, the Council then considered six penal cases which had been adjourned at previous meetings.

DAVID ELDER INFIRMARY AT GOVAN.—Plans for the building of this infirmary have now been approved and its erection will shortly be begun. The late Mr. Alexander Elder, of Liverpool, bequeathed £100,000 for the purpose in memory of his father and mother.

Correspondence.

"Audi alteram partem."

EFFECT OF SODIUM THIOSULPHATE ON THE THERAPEUTIC POWER OF ARSENOBENZOL COMPOUNDS.

To the Editor of THE LANCET.

SIR,—In a discussion on the toxic effects of arsenobenzol compounds, which was held by the Medical Society for the Study of Venereal Diseases on April 24th (THE LANCET, May 2nd, p. 926), I took the opportunity of saying that I had been wrong in an opinion expressed in the "Medical Annual" for 1925 (p. 444) that the injection of sodium thiosulphate simultaneously with arsenobenzol compound might act as an antidote which would protect the spirochæte of syphilis as well as the patient's tissues.

After I had returned the proofs of my article in the "Medical Annual" I thought it advisable to put this surmise to the test, and asked Dr. H. H. Dale, F.R.S., to say if the mixture of "914" with sodium thiosulphate raised or lowered the therapeutic dose of arsenobenzol as tested by its effect in causing the disappearance of trypanosomes from the blood of experimental animals. Dr. Dale kindly permits me to quote from his letter to the effect that "so far as our experimental trials have proceeded, there is no indication that dissolving the neosalvarsan preparations, before injection, in a 2·5 solution of sodium sulphate has any deleterious effect on the therapeutic action of the particular preparation on trypanosomiasis in mice."

Acting on this, I asked Dr. P. A. Clements to ascertain in the V.D. Department at St. Thomas's Hospital if a solution of "914" in 0·6 g. sodium thiosulphate interfered with the effect of the arsenobenzol compound in causing the disappearance of spirochætes from the serum of syphilitic lesions. Dr. Clements's observations support Dr. Dale's experimental evidence in showing that the thiosulphate does not interfere with the therapeutic action of "914" in this respect.

I am, Sir, yours faithfully,
L. W. HARRISON.

Eccleston-square, S.W., May 23rd, 1925.

"ORIENTAL SORE IN A NEW CENTRE IN PALESTINE."

To the Editor of THE LANCET.

SIR,—The annotation in THE LANCET of May 16th (pp. 1040–1041) on this subject recalls to my mind many war memories, and also a possible explanation.

Artuf is a small village, inhabited mainly by Bulgarian Jews, situated at the entrance to one of the strategic passes to Jerusalem, where the Philistine plain abuts on the Judean hills. Before the war the old Turkish narrow-gauge Jerusalem-Jaffa Railway ran through the village. When we captured Southern Palestine in the winter of 1917 the broad-gauge railway from Egypt was pushed up rapidly until it reached Artuf in the spring of 1918. Owing to engineering difficulties, however, the old Turkish line had still to be used from Artuf to Jerusalem for some months before the broad gauge could be pushed on to the Holy City. During this period, therefore, Artuf suddenly blossomed forth from an obscure village into an important entrepôt, for all stores, ammunition, and supplies for Jerusalem and the 20th Corps, amounting to 600–1000 tons per diem, had to be manhandled from the broad to the narrow gauge at this point. Naturally, this necessitated a large supply of Egyptian Labour Corps and Camel Transport Corps labour, and the men of these corps had to be provided with camps in and around the village. In addition, sick and wounded coming down from Jerusalem, mainly from the Jordan valley, had to be accommodated there until we could send a broad-gauge hospital train to evacuate them; and so a British casualty clearing station and an Egyptian detention hospital were stationed during this period at Artuf. Through these hospitals passed British and Egyptian sick and wounded from the Jordan valley, refugees from Amman and Es Salt across the Jordan, and Turkish prisoners of war.

A few cases of oriental sore are known to have been thus evacuated. Now, cutaneous leishmaniasis occurs endemically in Egypt, and considering the thousands of E.L.C. who mixed freely with the natives, and the presence of known cases in the hospitals, it would seem not unlikely that it was at this time (1918) the village became infected. A few months later the broad gauge was pushed on to Jerusalem, the hospitals and camps vanished, and Artuf once again became a mere wayside village; but probably in the interval the damage had been done. No one paid any attention to these people at that time. There was no resident doctor. The incubation period of oriental sore is sometimes as long as 15 months. The disease is not a dangerous one. It has a tendency to spontaneous cure, and it is quite likely that the condition has been overlooked until recently. That, I believe, is the real story of the outbreak.

I am, Sir, yours faithfully,

J. JOHNSTON ABRAHAM,
Formerly A.D.M.S. Lines of Communication,
Egyptian Expeditionary Force.

Harley-street, W., May 25th, 1925.

ULTRA-VIOLET LIGHT TREATMENT.

To the Editor of THE LANCET.

SIR,—Our knowledge of ultra-violet light therapy is rapidly improving and accumulating, considerably aided by such helpful communications as those of Dr. J. H. Sequeira and Dr. W. J. O'Donovan, and Dr. Howard Humphris, in your issue of May 2nd. I should like to emphasise certain aspects of this and other electrical treatments that impress me with their growing importance.

The first is the urgent need for organised research into the physical, physiological, and clinical effects of treatment by electricity. It is true that research work is already in hand on the effects of radium, X rays, and ultra-violet light, but I know of no team of workers in this country (including physicists and clinicians) whose reference is on the wider basis of electrical treatment as a whole. The recent striking advances in electro-physics have so stirred the imagination that many practitioners are now prepared to discuss the relative values of wave-lengths of 2000 and 3000 Angström units! This is symptomatic of a hunger for definite physical information, and it is the duty of the medical profession to see that this is provided without delay in as simple and accurate a form as possible. Already in America organised teams of clinicians and electro-physicists are at work.

The second conclusion that I have reached arises from the fact that I have obtained more rapid and impressive results from ultra-violet treatment during the last 18 months or two years than previously; and that owing to the recent dull and wet summers and winters we are suffering from a kind of famine of ultra-violet light. This is borne out by comparing the reactions of patients from London, the country, or abroad, and particularly striking is this difference in old people, just as if their storage capacity of sunlight were small and easily depleted or made up. If this conclusion is correct the need for increased efforts on behalf of smoke abatement becomes greater with each disappointing summer.

The third aspect to which I wish to draw attention is the great value of combining ultra-violet light with other forms of electrical treatment. Dr. Murray Levick has already described the favourable results he obtains in cases of poliomyelitis by using red rays and ultra-violet rays simultaneously. In such cases I have found that a combination of diathermy and ultra-violet treatment enhances the benefits derived from the diathermy current alone, great as these sometimes are.

Burns give surprisingly favourable results, particularly if the ultra-violet light falls on the burnt area and the surrounding skin, the former having a film of liquid paraffin over it. Paraffin, being fluorescent to ultra-violet waves, is therefore converting them to other wave-lengths, and an interpretation of fluorescence of this kind has recently been given by Prof. S. Russ and Dr. Peacock. Growth of the epithelium is more rapid, elastic, and healthy than by any other method I have seen, and dressings can be carried out with little or no pain. In fractures, especially where there is any reason to suspect delay in union, a combination of ultra-violet baths with the use of the direct current has invariably proved effective, since this method was instituted, two years ago. In cases of complete failure to unite, I have seen success achieved by this combination after many other attempts had failed.

Finally in cases of broncho-pneumonia and pneumonia the effect of combining diathermy and ultra-violet light is striking. I can confirm the American experience, and patients, both old and young, ask for their "hot pads" again and again. The effects observed are chiefly diminished restlessness and anxiety, a fall in the rate of respiration with greatly increased amplitude. A series of cases is now being collected which it is hoped will be ready for publication shortly. Combined research work would readily establish whether such apparently beneficial results were a matter of chance or genuine response to suitable electrical currents; and, if the latter, would undoubtedly indicate lines for technical physical improvement in apparatus.

I am, Sir, yours faithfully.

Portland-place, W., May 20th, 1925. C. B. HEALD.

CLEAN MILK IN HOSPITALS.

To the Editor of THE LANCET.

SIR,—In a letter just received from Dr. G. V. T. McMichael, medical officer of health for Paisley, I am informed that, following on a recent decision of the town council, only certified milk is now supplied to all the patients in the three municipal hospitals in Paisley—the fever hospital, the tuberculosis hospital, and the maternity and child welfare hospital. So far as I am aware, Paisley has therefore the distinction of taking the lead in establishing a much-needed reform. Reference may also appropriately be made to the model dairy established by Sir Robert Philip some years ago for the supply of clean milk to the tuberculosis hospital, as part of the general Edinburgh scheme for combating the disease, to the individual pioneer work (in Scotland) of Dr. E. P. Calder, of Stow, as a producer of clean milk on a commercial scale, and to the recent action of the County Council of East Lothian in securing clean milk for their sanatoriums.

For many years past a considerable amount of valuable work has been done on the subject of milk, notably at the National Research Institute for Dairying, under the direction of Dr. Stenhouse Williams, which has, however, largely remained outside the field of interest of the medical profession as a whole. It would appear that the time is now ripe for medical practitioners to interest themselves in this subject in a more intensive way than has so far prevailed. It is probably no exaggeration to say that, viewed from the necessary broad standpoint, there is no more pressing or vitally important question at the present time than the adequate provision throughout the country of a clean milk-supply.—I am, Sir, yours faithfully,

CHALMERS WATSON, M.D.

Edinburgh, May 20th, 1925.

POST-GRADUATE TEACHING IN MIDWIFERY.

To the Editor of THE LANCET.

SIR,—With reference to Dr. Margaret Balfour's letter on this subject in THE LANCET of last week, I should like to inform you that arrangements have now been made to provide practical post-graduate experience in midwifery at the Mothers' Hospital, Lower Clapton-road, E. The cost for a fortnight's course, including board and lodging, is 10 guineas, and includes delivery of normal cases, attendance at all operative work, at antenatal clinics, and at the rounds of the visiting staff in the wards. Special courses of operative midwifery and lectures will be arranged as desired at an extra fee. By the wish of the authorities of the hospital the course is confined to women post-graduates.

I am, Sir, yours faithfully,
FLORENCE E. BARRETT.
Devonshire-place, W., May 25th, 1925.

THE ALLEVIATION OF CHRONIC PROGRESSIVE DEAFNESS.

To the Editor of THE LANCET.

SIR,—Mr. Cathcart's article on the alleviation of chronic progressive deafness and persistent tinnitus by means of the Zund-Burguet method in your issue of May 9th is of great interest in so far as it applies to a class of disability usually considered to be incapable of amelioration.

Two points in the article call for comment. Mr. Cathcart states: "Of the total number of cases, 68 per cent. have definitely improved after treatment. These comprise 81 per cent. of the cases of nerve deafness, 67 per cent. of the cases of chronic otitis media, and 55 per cent. of the cases of otosclerosis." By otosclerosis I presume Mr. Cathcart means chronic catarrh of the middle ear. These results are so contrary to experience as to suggest a possibility of error. As a rule, when nerve deafness is diagnosed but little hope is entertained of any probability of amelioration. One would be interested to know if Mr. Cathcart has any probable explanation of the unusually favourable results obtained by this method.

The second point calling for comment is the statement that the improvement obtained after a full course of 30 sittings is only maintained for a period of from six to nine months. Such a prospect, if placed before these patients, is likely to be discouraging, and it would be interesting to know if after a second course of treatment there is any prospect of greater permanence of the benefit obtained.

I am, Sir, yours faithfully,
Highgate, N., May 18th, 1925. J. LAWSON DICK.

THE PROBLEM OF TUBERCULOUS MILK.

To the Editor of THE LANCET.

SIR,—The special article in your last issue by Dr. W. G. Savage on the Milk-supply and its Improvement has placed before our profession the facts of tuberculisation as they are, but I fear that Dr. Savage does not realise the position we as farmers and feeders are up against. No amount of supervision will prevent milk from being contaminated with the tubercle bacillus. It is not a question of supervision, but a question of education. Milk which has been contaminated with the tubercle bacillus is without any doubt injurious to human beings, and should not be allowed. It is indeed pathetic in these days of modern civilisation and scientific research that we should allow our population to be infected with bovine tuberculosis and, on the other hand, spend thousands of pounds in curing this infection. Preventive medicine has made enormous advancements, but yet the question of tuberculous infection from milk apparently has not been tracked.

When speaking at the Royal Society of Medicine a few months ago I stated that I could convert a tuberculous herd into a non-tuberculous herd, not by segregation, and certainly not by hygienic methods, but by proper methods of feeding. There is no one who knows the value of milk better than I do for feeding purposes, and I cannot find any food which is equal to milk for this purpose. Yet, on the other hand, I fail when I lecture on these points, as does Dr. Savage. The first half of my lecture is chiefly given up to the advantages of milk as a food and then I have to confess that one runs a great risk in feeding milk which has not been sterilised, knowing that sterilised milk has not the value for feeding purposes that natural milk has. The table summarised by Sir Henry Gauvain is sufficient evidence of the dangers of using milk unsterilised.

What, then, is the position of doctors to-day? We cannot conscientiously advise milk to be taken as provided by the cow unless it be from a certified herd in which every cow has passed the tuberculin test, but we all know that reactors occur, even in the best kept herds, and that one cow in a herd may infect the whole milk produced by that herd, and under modern methods of feeding and modern methods of milking I cannot see anything for it but that instead of having 40 per cent. to 50 per cent. of all cows in this country reacting to the tuberculin test, within a few years we shall have the percentage greatly increased. Those of us who are carrying out vitamin experiments are convinced that if you deplete a cow of the vitamin-A factor, by constantly milking her to the enormous extent that we do nowadays, that cow's resistance to tuberculosis is immediately lowered, with the result that infection is almost certain. Further, just think of the poor calf to-day—it is generally reared on artificial foods, chiefly linseed oil, which food is deficient in vitamin A, and we are only blowing on the wind as medical men.

It is far better for us to prevent the cow becoming infected than to deal with her products when it has become infected, and as the result of my experiments in animal nutrition, I am convinced that if you drain an animal of its vitamin content, by milking or suckling, you must replace that vitamin content by addition to its food, and if this were done tuberculosis amongst cows can be radically dealt with.

I am, Sir, yours faithfully,
M. J. ROWLANDS.
Southwood Farm, Westerham Hill, Kent,
May 25th, 1925.

BAKER'S ITCH AND WORKMEN'S COMPENSATION.

To the Editor of THE LANCET.

SIR,—Your legal correspondent in his note last week on this subject (p. 1049) refers to Dr. Prosser White's remarks at the Royal Society of Medicine, and quotes him as stating that "baker's eczema is unknown in France, and that American statistics point to a similar immunity being enjoyed by workers in the United States." Will you allow me to point out that this immunity can only be attributable to the fact that in these two countries the use of so-called "improvers" in the milling of flour is illegal, and that there should be no difficulty in tracing this complaint to the use of such preparations in this country? One of the commonest is potassium persulphate, which decomposes on the addition of water with liberation of oxygen and formation of potassium acid sulphate, the reaction being expressed as follows:—

$$2\ K_2S_2O_8 + 2\ H_2O = 4\ KHSO_4 + O_2.$$

I have been assured by various competent authorities that before the introduction of these "improvers" baker's itch was unknown in this country.

I am, Sir, yours faithfully,
J. T. AINSLIE WALKER, F.I.C., F.C.S.
Ludgate Hill, London, E.C., May 22nd, 1925.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON. — At examinations held recently the following candidates passed in the subjects indicated :—

Surgery.—F. T. Birkinshaw, Univ. Coll. ; M. R. Burke and T. G. L. Davies, St. George's ; N. H. Ibrahim, Durham ; C. S. Netscher, St. Mary's ; and R. J. Rutherford, Durham.

Medicine.—S. J. Alexander, Sydney ; M. R. Burke, St. George's ; J. H. Clapp, London ; J. Herbert, Guy's ; P. H. Knowles, Bristol ; O. W. Percival, Sydney ; W. Irving Pierce, Boston, U.S.A. ; J. Maingard, Guy's ; R. J. Rutherford, Durham ; B. Temple-Raston, St. Mary's ; I. Waynik, Charing Cross ; and M. E. G. Wilkinson, Bristol.

Forensic Medicine.—S. J. Alexander, Sydney ; F. T. Birkinshaw, Univ. Coll. ; J. H. Clapp, London ; D. T. Jenkins, Edinburgh ; I. H. Mackay, Sydney and Univ. Coll. ; J. Maingard, Guy's ; C. J. Rozario, St. Thomas's ; J. Shutt, London ; and B. Temple-Raston, St. Mary's.

Midwifery.—S. J. Alexander, Sydney ; F. T. Birkinshaw, Univ. Coll. ; A. F. Briglmen and D. T. Jenkins, Edinburgh ; E. W. D. Long, London ; and M. E. G. Wilkinson, Bristol.

The Diploma of the Society was granted to the following candidates entitling them to practise medicine, surgery, and midwifery : M. R. Burke, T. G. L. Davies, D. T. Jenkins, J. Maingard, O. W. Percival, R. J. Rutherford, and B. Temple-Raston.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.—At a meeting of the College held on May 20th, Sir Harold J. Stiles, President, in the chair, the 24 successful candidates out of 55 entered, who passed the requisite examinations between Jan. 12th and 19th, were admitted Fellows :—

Robert F. Allan, Bijitendra Basu, Edward J. Bilcliffe, Innes W. Brebner, Russell E. Butchart, Edwin Clark, Harold K. Corkill, Daniel de Bruyn, John A. Doctor, Francis H. Edwards, Frank Ll. Gill, Alan B. Jones, Gilbert E. José, Roshan L. Khera, Richard McAllister, Joseph A. MacFarlane, Colin C. Maclaurin, William J. Payne, Clive J. H. Sharp, Sydney S. Sumner, Cecil H. Terry, Geoffrey W. Theobald, John M. Watters, and John E. Wright.

The following candidates, having passed the requisite examinations, received the Higher Dental Diploma :—

George A. Edwards, William H. Lumb, and John K. Steel.

UNIVERSITY OF MANCHESTER. — At the June meeting of the University Court it was announced that a new development in connexion with the medical school had been made possible by the coöperation of the Royal Infirmary and the University in the appointment of a director of clinical research with a laboratory at the infirmary, and who would be appointed on the recommendation of a joint committee. On the recommendation of the senate and council, the Court agreed that Prof. Archibald Donald and Prof. George Redmayne Murray be made *Professores Emeriti*.

BELGRAVE HOSPITAL, LONDON.—An anonymous offer of £10,000 has been made to the Belgrave Hospital for Children towards the cost of building a new wing, on condition that a similar sum is raised. The wing will cost £27,000.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—The first of the new series of Fellowship lectures will be given at 5.30 P.M. on June 9th at 1, Wimpole-street, when Sir Thomas Horder will speak on Some Cases of Fever without Physical Signs.—A four weeks' course in the study of venereal diseases will be held at the London Lock Hospital (Dean-street) from June 2nd to 27th. Members of the staff will teach in the out-patients' department and will lecture on diagnosis and methods employed for combating these diseases. Early application should be made for this course, as it is only held if a sufficient number of entries are received.—There will be a course in dermatology at St. John's Hospital for Diseases of the Skin from June 2nd to 27th, consisting of instruction in the out-patient department and bi-weekly lectures dealing with various skin diseases.—From June 3rd to 25th eight clinical demonstrations on the more important diseases of tropical countries will be given at the London School of Hygiene and Tropical Medicine by Dr. G. C. Low and Dr. P. Manson-Bahr.—The Chelsea Hospital for Women will hold a course from June 8th to 27th, consisting of operations, demonstrations in the wards and out-patient department.—The Victoria Park Hospital has arranged a two weeks' course from June 8th to 20th, when the various diseases of the heart and lungs will be dealt with, either by demonstration or by lecture.—A special course in Urology will be held at St. Peter's Hospital from June 15th to July 11th. —An intensive course in Medicine, Surgery, and the Special Departments has been arranged by the London Temperance Hospital from June 22nd to July 4th.—Copies of the syllabus for the above courses may be obtained from the Secretary to the Fellowship of Medicine, 1, Wimpole-street, London, W. 1.

ORTHOPÆDICS IN WALES.—The sum of £50,000 has been anonymously placed at the disposal of trustees for the medical treatment of cripples in Wales.—The Committee of the Royal National Orthopædic Hospital has prepared plans for providing an additional 200 beds at the country branch at a cost of not less than £50,000. The present out-patient department is now "hopelessly inadequate," the total attendances last year having greatly exceeded 71,000, and plans have been laid for the extension of this department, the nurses' home, resident medical officers' quarters, and workshops at the cost of another £50,000.

LEICESTER PRIVATE HOSPITAL.—As we announced in our issue last week (p. 1093) a private hospital, the gift of Mr. T. Fielding Johnson, was opened in Regent's-road, Leicester, on May 20th. The opening ceremony was performed by Mrs. Fielding Johnson, and the guests, among whom were many prominent local people and representatives of public bodies, were received at the Museum by the President of the Leicester Medical Society, Dr. T. V. Crosby, and organisations in the city and county. The medical guests included Sir George Newman (Ministry of Health), Dr. R. A. Bolam, Mr. J. Basil Hall, Mr. N. Bishop Harman, Mr. H. S. Souttar (chairman of Council, president, treasurer, and chairman of Hospital Committee of the British Medical Association respectively), Sir H. D. Rolleston (President of the Royal College of Physicians of London), Sir J. Bland-Sutton (President of the Royal College of Surgeons of England), Sir W. A. Lane (President of the Fellowship of Medicine), Sir A. E. Garrod (Regius Professor of Medicine, Oxford), Dr. and Mrs. C. J. Bond, Dr. W. I. Cumberlidge, Councillor Dr. and Mrs. G. Brittan Gill, Dr. and Mrs. R. Wallace Henry, Dr. and Mrs. E. Lewis Lilley, Dr. and Mrs. W. W. Mackarell, Dr. and Mrs. N. I. Spriggs, Dr. and Mrs. Killick Millard, Dr. and Mrs. T. Robinson, Councillor Dr. and Mrs. A. T. Coleman, and Colonel Collis. Other medical men included were from Nottingham, Derby, Northampton, Kettering, Desborough, Rothwell, Spalding, Stamford, Grantham, and Peterborough. For two or three days before the ceremony the hospital had been open for public inspection, and was visited by large numbers of people.

ROYAL NORTHERN HOSPITAL.—On May 25th 14 of the beds closed in 1923 owing to lack of funds were reopened as a maternity department, this having been made possible by the generosity of the Women's United Services League, the Maternity Nursing Association, and the Ladies' League of the hospital. Sir Philip Sassoon spoke of the enormous development of North London during the last 50 years, and of the need in that district for a maternity service. This aspect was further emphasised by the Bishop of Willesden, who said that the Royal Northern, which was the sixth largest hospital in London, served an area of some 70 square miles and a population of about a million. Mr. Malcolm Donaldson, F.R.C.S., said that the three fundamental necessities for combating maternal mortality were the provision of antenatal care, hospitals where any abnormality could be recognised and treated at an early stage, and an efficient nursing service. The new maternity department was to be used as a training centre for midwives, and it was hoped to accommodate about 250 patients—mostly complicated cases—in a year. The Viscountess Jellicoe then declared the maternity department open. She had recently spent five years in New Zealand, where nearly every small town had its own maternity home, a matter in which England, she said, might take a lesson from the Dominion. After the ceremony the maternity department and other parts of the hospital were open to visitors. The Ladies' League maternity ward is the largest, containing five beds ; the Lady Jellicoe and the Lady French wards each have two, and there are several single-bed wards. Two of these are for patients able to pay private ward fees, while in the others prices will be accommodated to the patient's income. The light department, housed in an old army hut, has recently been completed. The hut has been divided into cubicles, which serve as treatment rooms for male and female patients, dressing- and waiting-rooms, a surgery and a room for a shower bath, though this has not yet been installed. An arrangement has been made by which children operated on for tonsils and adenoids can be kept in the hospital for 24 or 48 hours.

GLASGOW POST-GRADUATE MEDICAL ASSOCIATION. The following arrangements have been made for post-graduate teaching in Glasgow from June till October. The teaching facilities are in three forms : (*a*) General Medical and Surgical Course : During the last two weeks of August and the first two weeks of September a whole-time course, for which an inclusive fee will be charged, will be conducted in a number of the general and special hospitals. The course is arranged to include most of the subjects of interest to the general practitioner. On the four Saturday forenoons tuberculosis and infectious fevers will be demonstrated at Ruchill Fever Hospital. (*b*) Special Clinical Courses: Certain special classes have been arranged in several of the hospitals to suit the requirements of general practitioners, who have not very much time to devote to hospital work. (*c*) Clinical Assistantships: In a number of the institutions clinical assistantships are available during the summer months as well as at other times of the year. These clinical assistantships are limited in number, and have been designed to make provision for graduates who desire opportunities for the detailed study of one or other of the "specialties." Graduates may thus become attached to wards or out-patient departments, nominally as clinical assistants. As such they will work under the direct supervision of the physician or surgeon in charge, taking advantage of the facilities for intimate study of the cases, and carrying out such detailed investigations as may be directed. They will not be permitted to interfere, however, with the treatment of any patient. Any further information and a full syllabus of the courses will be supplied on application to the Secretary, Glasgow Post-Graduate Medical Association, the University, Glasgow.

HOME FOR RECOVERY AT LIVERPOOL.—Lord Derby on May 19th opened the Clifford Temple Home of Recovery, Aigburth, an adjunct of the David Lewis Northern Hospital, Liverpool. It consists of a mansion, for many years the residence of the Temple family, and is situated in ideal surroundings of six and a half acres of well-wooded grounds. It was bought and presented to the hospital by Mr. Clifford Temple, who accompanied the gift with a donation of 1000 guineas. The intention is to transfer patients from the Northern Hospital when they have passed the acute stage of their illness, thus liberating beds for new cases. There is accommodation for 25 adult male patients. The home is the first of its kind in Liverpool and it will cost £2000 a year to maintain it. Lord Derby expressed himself as strongly in favour of keeping our hospitals as long as we can from any Government or municipal control. Mr. K. W. Monsarrat, senior honorary surgeon, said the time had passed for building new hospitals in the city or to add to the number of their city hospital beds. The proper thing to do was to use the city hospital for emergency purposes, and when the stages of acute treatment are over, to send the patients to homes on the outskirts for recovery.

BRITISH ASSOCIATION MEETING AT SOUTHAMPTON. The annual meeting of the Association will be held at Southampton, where the Association previously met in 1846 and 1882, the session lasting from Wednesday, August 26th, to Wednesday, Sept. 2nd inclusive. The inaugural general meeting will take place in the Central Hall at 8.30 P.M. on the opening day, when Prof. Horace Lamb, F.R.S., will assume the presidency in succession to Sir David Bruce, F.R.S., and will deliver an address. Addresses by Sectional Presidents will be given during the following days as follows:—Psychology: Prof. C. Spearman, F.R.S., on Mental Law of Diminishing Returns. Zoology: C. Tate Regan, F.R.S., on Organic Evolution, Facts and Theories. Chemistry: Prof. C. H. Desch, F.R.S., on the Chemistry of Solids. Physiology: Prof. A. V. Hill, F.R.S., on the Physiological Basis of Athletic Records. Agriculture: Dr. J. B. Orr, on the Inorganic Elements in Animal Nutrition. Discussions will be held in the Section of Educational Science, on Health in Schools, Epidemics and Dietary; in the combined Sections of Psychology and Educational Science on Recent Investigations upon Vocational Guidance; and in the combined Sections of Physiology and Psychology, on the Acquisition of Muscular Skill. Arrangements have been made with the railway companies for the issue of return tickets to Southampton at a single fare and a third. The secretary of the Association is Mr. O. J. R. Howarth, O.B.E., M.A., Burlington House, London, W. 1.

ROYAL SANITARY INSTITUTE.—The thirty-sixth congress of the Institute will be held at Edinburgh from July 20th to 25th. The Duke of York is Honorary President of the congress, and Sir John Gilmour, Bart., M.P., Secretary for Scotland, as President, will deliver his inaugural address to the congress on July 20th. Already 675 delegates have been appointed from nearly 400 sanitary authorities from all parts of the United Kingdom. Delegates will also attend from Australia, India, South Africa, China, Egypt, France, Japan, U.S.A., New Zealand, Canada, Poland, and British West Indies. The meetings will be held in the University. The congress is divided into (*a*) sections: Sanitary science, engineering and architecture, maternity and child welfare, personal and domestic hygiene, industrial hygiene; and (*b*) conferences of various health authorities. The names of those who will preside over these meetings include Captain W. E. Elliot, M.P., Lieut.-Colonel Gerald Leighton, Sir George Newman, Prof. T. Hudson Beare, and Mr. A. Horsburgh Campbell. Over the meetings, more particularly of interest to the lady members, Lady Aberdeen, Lady Minto, Lady Mar and Kellie, and Lady Leslie Mackenzie will preside. Among the subjects of public health interest to be discussed may be mentioned the Government health policy, disease prevention, Schick test and diphtheria, occupation and the tuberculous, rheumatic heart disease, small-pox, cancer, plague, leprosy, diseases of children, open-air schools, midwifery, maternity hospitals, child welfare, homes for children, child gardens, toddlers' playrooms, day nurseries, house management, plumbers' work, reinforced concrete, sewerage of towns on tidal waters, river pollution, slum areas, water-supply, air pollution, milk and meat inspection, health visitor in India, work of a county health visitor, inspection of midwives. The lecture to the congress will be delivered by Sir Leslie Mackenzie, and the popular lecture by Dr. Charles Porter. The health exhibition, which is an important part of the congress, will include appliances for housing and general sanitation, and matters relating to health and physical welfare and domestic comfort, will be held in the Waverley Market. Full particulars of the congress may be obtained from the Secretary at the Royal Sanitary Institute, 90, Buckingham Palace-road, London, S.W. 1.

ROYAL MEDICAL BENEVOLENT FUND GUILD.—A produce market and fête will be held in aid of the Guild on June 24th in the Royal Botanic Gardens, Regent's Park, London, N.W.

ROYAL MEDICAL BENEVOLENT FUND.—At the last meeting of the committee 31 cases were considered and £547 voted to 28 applicants. The following is a summary of the new cases relieved:—

M.R.C.S. Eng., 1894, aged 55, unmarried, was a major in the R.A.M.C. A mental breakdown has rendered him unfit for any further work. A brother and four sisters contribute £130 towards his support, but one contribution of £36 per annum has ceased owing to the contributor's ill-health. The Fund was asked to make a grant to cover this amount and £30 was voted in 12 monthly instalments.

Widow, aged 57, of M.R.C.S. Eng. who practised in Monmouthshire and died in 1922. Applicant has tried to support herself by taking boarders, but owing to ill-health and lack of boarders has got into debt. She has had to sell her trinkets and late husband's books to help to pay her way. Total debts amount to £23. Income from boarders £117. Voted £18 in 12 monthly instalments.

Widow, aged 31, of M.B. Aberd. who practised in London and died from tuberculosis in August of last year. Applicant and daughter, aged 6, are left with £3 a week, which will last for another 18 months. She pays her parents £2 10*s*. a week for herself and child for board and lodging. Applicant is training as a lady hairdresser and the Scottish Corporation found the sum of £30 for the course and asked the Fund to help towards this amount. The Fund voted £15.

M.R.C.S. Eng., aged 68, who practised in Lancashire until ill-health compelled him to give up. Applicant's daughter has tried to support herself and her father, but is now trying to get him in a home as he requires constant attention. The boarding house which the daughter has had is a failure and she now wants to get a post so as to be self-supporting. She asks for a grant as the applicant has no income. Voted £40 in 12 instalments.

Subscriptions may be sent to the Hon. Treasurer, Sir Charters Symonds, at 11, Chandos-street, Cavendish-square, London, W. 1.

DONATIONS AND BEQUESTS.—Mr. Edwin Sutton, of Higher Broughton, Manchester, left, on his wife's death, £1000 to endow an E. and B. Sutton bed in Salford Royal Hospital requesting that as far as possible this should be used preferably for the Sons of Temperance, Salford Grand Division.—Mr. Alfred Hassall Straker, of Oakham, Rutland, and Newcastle-upon-Tyne, left £12,000 to charities, including £5000 to Dr. Barnardo's Homes.—Sir George Wheaton Fox, sugar merchant, of Liverpool, by his will provided £17,000 for charities, as well as gifts to employees. He left £2000 each to the Royal Infirmary and the Blue Coat School, Liverpool; £1000 each to the Royal Southern Hospital, the David Lewis Northern Hospital, the Stanley Hospital, the Liverpool Seamen's Orphanage; and £500 to the Birkenhead Borough Hospital; also a personal bequest of £1000 to Dr. Richard Thacker King, of West Kirby.—Sir William Cresswell Gray, of Bedale, Yorks, shipbuilder, West Hartlepool, left £5000 to the Hospitals Trusts of the Hartlepools; £5000 for a Gray Convalescent Home for his employees, and £250 per annum towards upkeep; and £2000 to the Victoria Homes, West Hartlepool.—Miss Mary Russell, of Cheetham Hill, Manchester, who left estate of the value of £60,525, after fulfilment of a number of personal legacies, left the residue of her property, computed to be about £50,000, to be divided equally between the Christie Hospital Cancer Pavilion and Home, Manchester, St. Mary's Hospitals, Manchester, the Manchester Royal Infirmary, the Manchester Eye Hospital, the Salford Royal Hospital, and the Royal National Lifeboat Institution.—Mr. John William Richardson, of Walmer, Kent, who left property of the value of £11,877, gave, subject to certain legacies and life interests, the ultimate remainder of his property to the Miller Hospital for South-East London, the Seamen's Hospital, Dreadnought, and the Deal and Walmer

Victoria Hospital.—The late Sir George A. Critchett, surgeon oculist to the King, left by will £100 to Epsom College and £100 to the Royal Medical Benevolent Society. —An anonymous donor has made offer of £10,000 for an extension scheme of Hull Victoria Children's Hospital, conditional on another £10,000 being raised. Immediate offers of £500 each were made by Mr. G. J. Bentham and Messrs. Reckitt and Sons.—At the spring meeting of the governors of the University College of Wales at Barmouth, it was announced that the Misses Davies, of Llandinam, who had already subscribed very generously towards the College, had sent a gift of £2500 to clear the bank overdraft on the Edward Davies Chemical Laboratories, Aberystwyth. —Mr. W. Henry Hutchinson left £100 to the Leicester Royal Infirmary.—Mr. David Isaacs, Cape Town, South Africa, left £100 each to the London Hospital, the Jews Hospital and Orphan Asylum, the Jewish Deaf and Dumb Home, the Jewish Institution for Indigent Blind, the Hospital for Consumption and Diseases of the Chest, London, S.W., the Metropolitan Hospital, London, and the Middlesex Hospital. Also £100 each to ten institutions in Cape Town.—Dr. May Thorne, one of the governors of the Royal Free Hospital, during a sojourn in the United States, collected £1500 for the endowment of beds in the George Washington Ward of the hospital—the only ward of its name in the world. Hopes are entertained of receiving shortly a further £3500, also from America.—Mr. Thomas McLaren Davidson, Dundee, on the death of a legatee, left £1050 to Dundee Royal Infirmary, to endow a cot in the children's ward, to be known as the "Thomas McLaren Davidson and Margaret Davidson Cot."—Mr. Arthur Turner, Southam, Warwickshire, who left estate of the gross value of £34,974, failing issue to his daughter, gave the ultimate residue of his estate, as to five-twelfths to the Warneford Hospital, Leamington, one-twelfth each to the Midland Counties Home and Hospital for Incurables, and the Royal Devonshire Hospital, Buxton.

MEDICAL WOMEN'S FEDERATION.—The annual meeting was held in the rooms of the Medical Society of London on May 7th. The annual report showed that during the year the membership of the Federation largely increased, the total membership on Dec. 31st, 1924, being 900. Reports from the various committees of the Federation were received and discussed by the council at a meeting held on May 8th and 9th, under the presidency of Miss Frances Ivens. The report of the Standing Committee for the Defence of Married Medical Women dealt with the action taken in connexion with the resolution of the London County Council, passed last October, making married medical women ineligible for posts on the Council staff. The objects aimed at were the rescinding of the standing order against the employment of married women workers in general, and the establishment of the principles of free choice of candidates and the consideration of cases on their own merits. In connexion with the report of the subcommittee appointed to consider the Nursing Homes (Registration) Bill, motions were passed—

> (1) That in the case of the house of a doctor taking in patients, the inspection should be carried out by a medical practitioner, and not by a nurse; and (2) no doctor who has a professional plate already fixed to the exterior of the house shall be compelled to display in addition the fact that the house is used for resident patients—this should not exempt the doctor from the duty of registration under the Act, nor from inspection which in the case of a doctor should be carried out by a medical officer.

It was recommended that the house of a medical practitioner taking in not more than one patient for treatment or supervision should be exempted from inspection. Reports were also received from representatives of the Federation on Committees of the British Medical Association. Some discussion arose on the report of the representative on the B.M.A. Insurance Acts Committee, and the following resolution was passed:—

> That in the event of the extension of the National Health Insurance medical benefits to wives and adult dependants of insured persons, the general principle of the free choice of a doctor should be jealously guarded.

The progress in various countries of the Medical Women's International Association was recorded by the National Corresponding Secretary. The Medical Secretary reported that a large number of underpaid posts had been advertised, and that the Federation had approached any women candidates applying for these in any case coming under their cognisance. Several had withdrawn in consequence. Considerable discussion arose on the salaries in public health posts and the amount of experience that should be required from candidates for such posts. It was resolved—

> That in the opinion of the Council of the Medical Women's Federation, the doctors to be appointed as assistant medical officers of health at £600 a year should have had at least three years' post-graduate experience, such experience to include work which should specially qualify for the post, and if possible some time in general practice. For the third year a minor public health appointment at £500 a year might be accepted.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Bills Advanced.

ON Thursday, May 21st, the Poor-law (Emergency Provisions Continuance Scotland) Bill was considered on report and read a third time. The Pensions Bill was considered on report and agreed to.

HOUSE OF COMMONS.

WEDNESDAY, MAY 20TH.

Maternity and Child Welfare Centres.

Mr. GROVES asked the Minister of Health the number of child welfare centres in the various localities in actual operation at present.—Sir KINGSLEY WOOD (Parliamentary Secretary to the Ministry of Health) replied: According to the information in the possession of my right hon. friend's department the number of maternity and child welfare centres in England and Wales in operation on May 1st was 2368.

Tuberculosis Statistics.

Lieut.-Colonel HENEAGE asked the Minister of Health if he could give the total number of people in Great Britain suffering from tuberculosis in 1924, and the number of deaths; the total number of children under 14 years suffering from tuberculosis of the glands and bones, and the number of deaths; if he could give the numbers traced to milk infection; and all the above figures for Lincolnshire.—Mr. N. CHAMBERLAIN replied: I regret that information is not available as to the total numbers of persons who were suffering from tuberculosis in 1924. I have, however, recently issued special regulations as the result of which reliable data should be available next year as to the numbers of tuberculous persons whose cases have at any time been notified to medical officers of health and who are still suffering from the disease at the end of 1925. The number of deaths in England and Wales in 1924 from all forms of tuberculosis was 41,103; and in Lincolnshire (including the county boroughs of Lincoln and Grimsby) 636. The number of deaths of persons under 15 years of age from tuberculosis of the glands and bones in England and Wales was 72. Separate figures for Lincolnshire are not at present available. I cannot say in how many of these cases milk infection was traced. Researches made on behalf of the Medical Research Council would, however, indicate that, in a series of cases of bone and joint tuberculosis in children, the infection was found to be of bovine origin in some 20 per cent. of the cases; whilst in cases of gland tuberculosis the percentage was considerably higher.

Vaccination Marks.

Mr. WHITELEY asked the Minister of Health whether he was aware that modern methods of vaccination tend to produce faint marks which sometimes disappear; and whether the medical officials of the Ministry based their classifications of small-pox cases in regard to the vaccinal condition on the presence or absence of the vaccination mark.—Mr. N. CHAMBERLAIN replied: I am advised that the marks produced by modern methods of successful primary vaccination seldom disappear. Small-pox cases are classified in the annual reports of the chief medical officer of my department under the following headings: (*a*) Vaccinated as evidenced by presence of one or more vaccination cicatrices; (*b*) stated to have been successfully vaccinated, but no vaccination cicatrix present; (*c*) stated to be unvaccinated (or vaccinated unsuccessfully) and no vaccination cicatrix present; (*d*) previously unvaccinated, but vaccinated during incubation of small-pox; (*e*) stated to have been successfully revaccinated.

Deaths of Women in Childbirth.

Mr. GROVES asked the Minister of Health whether he was aware that over 4000 women died per year in Great Britain at childbirth; whether he was prepared to circularise all local authorities to urge the establishment of antenatal clinics, where the best skilled advice would be obtainable, and arrange, where the prospective mother was too poor to engage the services of a qualified medical man, that this service should be provided freely; and whether he would cause investigation to be made relating to the present provision of maternity homes.—Mr. N. CHAMBERLAIN replied: I am sending the hon. Member a copy of a circular on the subject of maternal mortality addressed to local authorities on June 30th, 1924, together with a copy of the report referred to in the circular which gives statistics relating to maternity mortality in England and Wales. This circular impresses upon maternity and child welfare authorities the importance both of antenatal supervision and of the provision of specialist advice and treatment for necessitous patients whenever necessary. Under the Midwives Acts the services of a doctor are available in emergencies without cost to the patient if she is unable by reason of poverty to pay the doctor's fee. The circular also urges the provision of maternity beds, and in individual cases local authorities are recommended to make good any deficiencies in this respect which are discovered as the result of inspections by my medical officers. I see no need for any special investigation on this point.

Deaths from Infectious Diseases.

Mr. Rhys Davies asked the Minister of Health whether he would give, in tabular form, the number of deaths from influenza, scarlet fever, measles, whooping-cough, chicken-pox, sleepy sickness, and small-pox for each of the last ten years.—Mr. N. Chamberlain replied: The required figures for England and Wales are as follows:—

Year.	Influenza.	Scarlet fever.	Measles.	Whooping-cough.	Chicken-pox.	Encephalitis lethargica.	Small-pox.
1915 ..	10,484	2,406	16,445	8,143	92	—	13
1916 ..	8,791	1,381	5,413	6,075	65	—	18
1917 ..	7,289	768	10,538	4,509	69	—	3
1918 ..	112,329	1,020	9,787	9,898	54	16	2
1919 ..	44,801	1,221	3,534	2,605	55	294	28
1920 ..	10,665	1,430	7,190	4,401	71	480	30
1921 ..	8,995	1,305	2,241	4,576	57	729	5
1922 ..	21,498	1,382	5,694	6,370	40	339	27
1923 ..	8,461	993	5,316	4,162	52	531	7
1924 ..	18,986	888	4,834	3,983	59	1,407	13

THURSDAY, MAY 21ST.

Revision of Medical Awards.

Captain Gee asked the Minister of Pensions whether awards made by medical boards were subject to revision by officials of his department.—Major Tryon replied: Under the terms of the Royal Warrant pension can only be awarded in accordance with the rate of assessment certified by a medical board, or a medical officer of the Ministry. In point of fact, every award made by my department under the Royal Warrant is in accordance with the assessment given by a medical board which has actually seen and examined the man.

Electrocardiograph for Pensioners.

Captain Gee asked the Minister of Pensions whether his department possessed an electrocardiograph; and, if not, would he consider the advisability of obtaining one in the interests of ex-Service men suffering from cardiac disability.—Major Tryon replied: Arrangements have been in force for some years with local institutions whereby the Ministry obtain electroradiograms in all cases where this is medically considered necessary. The nature of the Ministry's work, whereby medical examination is carried out in the interest of pensioners at a variety of centres throughout the kingdom, has not made it practicable to adopt my hon. friend's suggestion.

Procedure in Coroners' Courts.

Mr. Dixey asked the Home Secretary whether he had any statement to make as to when he proposed to introduce legislation to regulate or abolish the procedure of double inquiries of magistrates' courts and coroners' courts in murder and manslaughter cases.—Sir W. Joynson-Hicks replied: I hope to introduce the Coroners Bill very shortly.

Approved Societies and Hospital Payments.

Mr. Grundy asked the Minister of Health how many approved societies and branches have agreed to devote a portion of their surpluses to payments in respect of hospital treatment of their members to the funds of voluntary hospitals; and what was the sum given to voluntary hospitals under agreements with approved societies during the 12 months ending March 31st, 1925.—Mr. N. Chamberlain replied: The number of societies and branches in England whose existing schemes of additional benefits include payments to hospitals or convalescent homes is 963, with a membership of about 5 million insured persons. The sum spent under this additional benefit during the year ended Dec. 31st, 1924, was about £210,000. It is not possible to state how much of this sum was paid to hospitals, as distinct from convalescent homes, but it is believed that by far the greater part was paid in respect of the treatment of members in hospitals.

Powers of the General Medical Council.

Mr. Basil Peto asked the Minister of Health whether he would consider the amendment to the Medical Act of 1858 in order to give a right of appeal to medical practitioners struck off the Register by decisions of the General Medical Council holding them guilty of infamous conduct.—Mr. N. Chamberlain replied: I am not aware that there is any general demand among the medical profession for the amendment of the Medical Acts in the direction suggested by my hon. friend, and in the absence of general agreement I am not prepared to introduce legislation.

Mr. Peto: Does the right hon. gentleman not think that the absolutely autocratic powers over the lives and careers of the whole medical profession which the General Medical Council has under the Act of 1858 require some revision?

Sir H. Craik: Is it the experience of the right hon. gentleman's department that the action of the General Medical Council has been highly expedient in the interests of health and the community generally?

Mr. N. Chamberlain: If there were any general feeling among the medical profession that the powers of the General Medical Council were excessive I do not think I should have any difficulty in ascertaining it. They have not generally been backward in putting forward any grievance.

Instruction in Manipulative Surgery.

Mr. Basil Peto asked the Minister of Health whether, in the interest of public health, he would consider legislative action to insure that persons qualified to give practical instruction in manipulative surgery should have the opportunity of giving it and also of obtaining degrees in this branch of surgery.—Mr. N. Chamberlain replied: Under the revised medical curriculum adopted by the General Medical Council in 1922 practical instruction in manipulative surgery can be, and is, given by persons holding registrable medical qualifications. As at present advised I am not prepared to recommend legislation for the purpose of establishing degrees or diplomas for persons who have not satisfied the statutory requirements of the General Medical Council.

Scientific Research.

Mr. Herbert Williams asked the Prime Minister whether action, to ensure adequate coördination in respect of the whole of the expenditure exceeding £4,000,000 provided in this year's estimate for scientific research, was being taken by the Lord President of the Council.—Mr. Baldwin replied: My noble friend, the Lord President of the Council, has no responsibility for ensuring adequate coöperation in respect of the whole of the expenditure for scientific research, which is estimated for 1925–26 to exceed £4,000,000, but the Department of Scientific and Industrial Research and the Medical Research Council, for whose activities the Lord President is responsible, is so far as the first-named department is concerned, provided with machinery for the coördination of the research work of the technical establishments of the fighting services which has a civilian interest and of certain other Government departments. The department has no control over the work of the research establishments maintained by other Government departments, and has no responsibility in connexion with research undertaken purely for defence purposes. Conferences between representatives of the Department of Scientific and Industrial Research, the Medical Research Council, and the Development Commission are held periodically for the consideration of matters of common interest to these departments.

Cost of Tuberculosis Treatment.

Colonel Day asked the Minister of Health the total amount spent by local authorities on tuberculosis treatment in the years 1923 and 1924 respectively, including capital expenditure.—Mr. N. Chamberlain replied: The following table shows the gross expenditure, so far as information is at present available, of local authorities in England and Wales on the treatment of tuberculosis, during the financial years ended on March 31st, 1923 and 1924:—

—	Year ended March 31st—	
	1923.	1924.
	£	£
Capital expenditure defrayed out of loans on capital grants ..	348,748	Not yet available.
Other expenditure	2,749,073	2,766,131

Deaths from Hydrochloric Acid Poisoning.

Colonel Day asked the Minister of Health the number of deaths caused by persons drinking spirits of salts during the year 1924; whether he was aware that the sale of this dangerous poison was on the increase; and if he would take any action that will make the same less accessible.—Mr. N. CHAMBERLAIN replied: The figures for the year 1924 are not yet available. The number of deaths from hydrochloric acid poisoning in 1923 were: suicides 73 and accidents 7. These figures do not differ appreciably from those of the two previous years, and on the information at present available there does not appear to be any ground for increasing the restrictions on the sale of hydrochloric acid already imposed by Section 5 of the Poisons and Pharmacy Act, 1908.

Deaths from Small-pox.

Mr. BROAD asked the Minister of Health the ages of the 13 persons registered in 1924 as dying from small-pox and the districts in which those deaths were registered; and whether any other disease was mentioned on the death certificate.—Mr. N. CHAMBERLAIN replied: The following table gives the particulars asked for:—

Sex and age.	(*a*) Area in which death occurred. (*b*) Area of residence.	Cause as certified.
M., 10 mths.	(*a*) (*b*) Hucknall.	Sm.-p.; marasmus.
F., 15 ,,	(*a*) (*b*) Middlesbrough.	Whooping-cough; broncho-pneum.; sm.-p.
F., 9 ,,		Sm.-p.; convulsions
M., 15 yrs. . .	(*a*) Plymouth; (*b*) Stockton-on-Tees.	Sm.-p.
M., 2 mths. . .	(*a*) (*b*) Stapleford.	Variola.
M., 24 days	(*a*) (*b*) East Dean and United Parishes.	Sm.-p.
F., 22 mths.		Sm.-p.; measles; convulsions during convales.
F., 14 yrs. . .	(*a*) (*b*) Chesterfield.	Congen. cretinism; valv. heart dis.; dropsy; sm.-p.
F., 28 days. .	(*a*) (*b*) Barnsley.	Congen. debility; variola.
F., 36 yrs.	(*a*) Kingsbury; (*b*) Willesden.	H. sm.-p.
M., 7 ,,		H. sm.-p.; cardiac failure.
F., 39 ,,		Ditto.
F., 52 ,, . .	(*a*) (*b*) Ashington.	Pelvic abscess; sm.-p.

H. sm.-p. = Hæmorrhagic small-pox.

MONDAY, MAY 25TH.

Naval Ratings and Tuberculosis.

Sir BERTRAM FALLE asked the Parliamentary Secretary to the Admiralty what percentage of naval ratings invalided during the year 1924 owing to tuberculosis was attributable to service; and what percentage was considered to be not attributable to service.—Mr. DAVIDSON replied: The percentages are 4 per cent. and 96 per cent. respectively.

TUESDAY, MAY 26TH.

Books on Technical Subjects.

Mr. J. B. COUPER asked the President of the Board of Trade whether he would introduce legislation making compulsory the insertion in every book of the date of compilation or of issue, in view of the mass of technical literature published in recent years and the difficulty in ascertaining readily the most up-to-date publications on various technical subjects.—Sir BURTON CHADWICK (Parliamentary Secretary to the Board of Trade) replied: I cannot hold out any prospect of such legislation.

Scottish Medical Insurance Officers' Reports.

Mr. JOHNSTON asked the Under Secretary to the Scottish Board of Health if he would make available for the inspection of members in the library copies of the reports for the year 1924 of the district medical insurance officers under the Scottish Board of Health for the cities of Edinburgh, Glasgow, Aberdeen, and Dundee.—Captain ELLIOT replied: The reports in question are of a confidential nature, and it would not be in the public interest to publish their contents in full. A summary of salient features with extracts relating to points of special interest will, however, be embodied in the Board's annual report for 1924, which will be made available at the earliest possible date.

Dr. G. F. Buchan has been elected President of the Society of Medical Officers of Health for the session 1925–6.

EXTENSION OF DUNDEE ROYAL INFIRMARY.—Through a gift of £25,000 from Mrs. Marryat, Dundee Royal Infirmary has just been able to open an extension of the Caird Pavilion comprising operation theatres and a medical electrical department.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MEETINGS OF SECTIONS.

Wednesday, June 3rd.

SURGERY: at 5.30 P.M.
Paper:
Dr. Charles H. Mayo: A Consideration of Gastric and Duodenal Ulcer.
(See below under Saturday, June 6th.)

Thursday, June 4th.

OBSTETRICS AND GYNÆCOLOGY: at 8 P.M.
Annual General Meeting (adjourned from May 7th):
Election of Officers and Council.
Election of Corresponding Member.
To be followed immediately by the Ordinary Meeting.
Specimens:
Mr. A. C. Palmer: Endometrioma of Perineum and Vulva (three cases).
Mr. Aleck Bourne: (1) Chorion-epithelioma; (2) Chronic Metritis as a Cause of Sustained Pyrexia.
Papers:
Dr. Abernethy Willett: Placenta Prævia treated by Traction on the Fore-coming Head.
Mr. D. C. L. Fitzwilliams (introduced by Mr. C. White): Curiosities in Connexion with the Secretion of Milk.

Friday, June 5th.

LARYNGOLOGY: Summer Meeting.
Papers: at 9.30 A.M.:
Dr. Tapia (Madrid): The Big Pharyngostomes as an Accident in Laryngectomy. How they can be avoided and way of closing them.
Followed by Mr. Wilfred Trotter and Mr. Lionel Colledge.
Prof. Burger (Amsterdam): Speech after Laryngectomy (with exhibition of a patient).
Demonstrations:
Mr. Lionel Colledge: McKenty-Western Artificial Larynx (with exhibition of patients).
Mr. R. Graham Brown (Brisbane): An Artificial Larynx.
Papers:
Dr. Charles Mayo: Methods of Caring for Diseases of the Pharynx, Larynx, and Mouth.
Dr. Ritchie Rodger (Hull): Tracheotomy in Tuberculous Laryngitis.
Microscopical and Lantern Demonstration:
Dr. A. Logan Turner and Dr. F. E. Reynolds (Edinburgh): Furuncle of the Nasal Vestibule and Cavernous Sinus Thrombosis; the Pathway of Infection.
Kinematograph Film:
Sir Charles Ballance and Mr. Lionel Colledge: Restoration of Movement in Vocal Cord after Nerve Anastomosis.
Papers:
Dr. J. S. Fraser: Intranasal Dacryocystotomy.
Dr. A. Lowndes Yates: The Sinus Condition in Encephalitis Lethargica.
Cases and Specimens will be shown at 3 P.M. by Mr. Douglas Guthrie, Mr. Harold Kisch, Mr. R. Graham Brown, Dr. Jobson Horne, Sir James Dundas-Grant, Mr. Ridout, Mr. Jefferson Faulder, Mr. Herbert Tilley, and Dr. Dan McKenzie.

Saturday, June 6th.

OTOLOGY: at 10.30 A.M. (Cases at 9.45 A.M.)
General Discussions:
Methods of Drainage of Brain-abscesses.
Artificial Aids to Hearing.
Cases and Specimens will be shown.

SURGERY.
A Dinner will be given by the Section in honour of Dr. Mayo, on the evening of Saturday, June 6th, at the Hotel Cecil, at 7.30 P.M. Tickets, exclusive of wine, 15*s.* each.
All applications for seats must be accompanied by cheque for the number of tickets required, and should be sent to the Hon. Secretaries of the Section, at 1, Wimpole-street, W., by Saturday, May 30th.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, June 1st, to SATURDAY, June 6th.—LONDON LOCK HOSPITAL, Dean-street. Comprehensive Course. Daily Instruction in Out-patient Departments and lectures by members of the staff.—LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE, Endsleigh-gardens, N.W. Tuesday and Thursday, 2 P.M., Lecture-demonstrations by Dr. P. Manson-Bahr and Dr. G. C. Low.—ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, Leicester-square. Daily Demonstrations in the Out-patient Department. Bi-weekly lectures by Dr. Griffith and Dr. Sequeira.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

Tuesday, June 2nd.—12 noon, Dr. Burrell: Chest Cases. 2 P.M., Mr. Sinclair: Surgical Out-patients. 3 P.M., Dr. Pritchard: Medical Wards.

Wednesday.—11 A.M., Medical Registrar: Medical Wards. 2 P.M., Dr. Owen: Medical Out-patients. 2.30 P.M., Mr. Donald Armour: Surgical Wards.

Thursday.—10 A.M., Dr. Grainger Stewart: Neurological Dept. 11 A.M., Sir Henry Simson: Gynæcological Wards. 2 P.M., Mr. MacDonald: Genito-Urinary Dept.

Friday.—10 A.M., Dr. Dowling: Skin Dept. 12 noon, Surgical Registrar: Surgical Pathology. 2 P.M., Mr. Vlasto: Throat, Nose, and Ear Dept.

Saturday.—10 A.M., Dr. Saunders: Medical Diseases of Children. 10 A.M., Mr. Banks-Davis: Operations on Throat, Nose, and Ear.

Daily, 10 A.M., to 6 P.M., Saturdays, 10 A.M. to 1 P.M., In-patients, Out-patients, Operations, Special Departments.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C. 1.

POST-GRADUATE COURSE: MAY–JUNE, 1925.

CLINICAL LECTURES AND DEMONSTRATIONS.

Tuesday, June 2nd.—2 P.M., Out-patient Clinic: Dr. Walshe. 3.30 P.M., Disorders of Gait: Dr. Risien Russell.

Thursday, June 4th.—2 P.M., Out-patient Clinic: Dr. Kinnier Wilson. 3.30 P.M., Encephalitis Lethargica and its Sequelæ: Dr. Hinds Howell.

Friday, June 5th.—2 P.M., Out-patient Clinic: Dr. Gordon Holmes. 3.30 P.M., Some Types of Myopathy: Dr. James Collier.

COURSE OF LECTURES AND DEMONSTRATIONS ON THE PATHOLOGY OF THE NERVOUS SYSTEM.

Monday, June 8th.—12 noon, The Neuron: Dr. J. G. Greenfield.

COURSE OF LECTURES AND DEMONSTRATIONS ON THE ANATOMY AND PHYSIOLOGY OF THE NERVOUS SYSTEM.

Tuesday, June 2nd.—12 noon, The Basal Ganglia: Dr. Walshe.

Thursday, June 4th.—12 noon, The Forebrain: Dr. Walshe.

Dr. H. J. Macbride will give a COURSE OF EIGHT CLINICAL DEMONSTRATIONS, chiefly on METHODS OF EXAMINATION OF THE NERVOUS SYSTEM, in the Wards at 10 A.M. on Tuesdays and Fridays, if sufficient entries are received. The fee for this Course will be £2 2*s*. (commenced Tuesday, May 19th).

Mr. Armour and Mr. Sargent operate at the Hospital on Tuesday and Friday mornings at 9 A.M., or at such other times as may be announced.

Any part of the Course may be taken separately. Special arrangements will be made for those unable to take the whole Course.

Fees should be paid to the Secretary of the Hospital at the office on entering for the Course.

J. G. GREENFIELD, Dean of Medical School.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

Tuesday, June 9th.—4.30 P.M., Dr. J. K. C. Laing: Demonstration of Cases of Mental Disease (at the Mental Hospital, New Southgate, N.).

Friday.—4.30 P.M., Mr. A. E. Giles: Treatment by Radiation in Gynæcology.

Daily.—Clinics in General and Special Departments, Demonstrations, Operations, &c.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, Leicester-square, W.C.

Tuesday, June 2nd.—5 P.M., Dr. Griffith: The Bullous Eruptions.

Thursday.—5 P.M., Dr. Sequeira: Dermatitis Artefacta.

ST. MARY'S HOSPITAL INSTITUTE OF PATHOLOGY.

Thursday, June 4th.—5 P.M., Sir Arthur Keith: The Structural and Functional Disorders of the Great Bowel.

UNIVERSITY OF LIVERPOOL POST-GRADUATE LECTURES. (At 3.30 P.M.)

Wednesday, June 3rd.—(At the Northern Hospital.) Dr. H. S. Pemberton: The Treatment of Dyspepsia.

Thursday.—(At the Stanley Hospital.) Dr. Gullan: Diabetes and its Treatment.

Appointments.

FRAZER, W. M., M.B., Ch.B. Liverp., D.P.H., has been appointed Medical Officer of Health, Dewsbury.

MCFADDEN, GEORGE D. F., M.B., M.Ch., F.R.C.S. Eng., Assistant Surgeon to the Ulster Hospital, Belfast.

MURRAY, GEORGE R., M.D. Camb., F.R.C.P. Lond., Emeritus Professor of Medicine in the Victoria University of Manchester and Consulting Physician to the Manchester Royal Infirmary.

PORTEOUS, A. B., M.D., B.S. Lond., D.P.H., Acting Medical Officer of Health and Administrative Tuberculosis Officer, Paddington.

ROBERTSON, J. K. A., M.D. Edin., to be one of the Medical Referees under the Workmen's Compensation Act for the Greenock District.

King's College Hospital: MITCHELL, A., M.R.C.S., L.R.C.P., STRAUSS, E. B., B.M., B.Ch., POWELL, R. V., M.R.C.S., L.R.C.P., OSBORN, M. M., M.R.C.S., L.R.C.P., FRANKLIN, E. L., M.R.C.S., L.R.C.P., ROBERTSON, N. L. D., M.B., B.S., FISH, W. M., M.R.C.S., L.R.C.P., PENNETT, G. M., M.R.C.S., L.R.C.P., HERBERT, F. K., M.R.C.S., L.R.C.P., MALMBERG, M., M.R.C.S., L.R.C.P., and BUCKLEY, O. B., M.R.C.S., L.R.C.P., additional Clinical Assistants; PERKINS, A. C. T., M.B., B.S., and SIMPSON, A. S., M.R.C.S., L.R.C.P., Casualty Officers; TOWNSEND, H. S., M.R.C.S., L.R.C.P., House Anæsthetist; NEWMAN, C. E., M.B., B.Ch., WOOD, C., M.R.C.S., L.R.C.P., COLLIS, W. R. F., M.R.C.S., L.R.C.P., COVE-SMITH, R., M.R.C.S., L.R.C.P., and READ, T. S., M.R.C.S., L.R.C.P., House Physicians; COOPER, H. A., M.R.C.S., L.R.C.P., DYER, R. H., M.R.C.S., L.R.C.P., DAGGETT, W. I., M.R.C.S., L.R.C.P., AHRENS, B. E., M.R.C.S., L.R.C.P., CORY, J. W. E., M.R.C.S., L.R.C.P., STRANGE, F. O. T., M.R.C.S., L.R.C.P., APPLETON, C. E., M.R.C.S., L.R.C.P., and ADLINGTON, B., M.R.C.S., L.R.C.P., House Surgeons; EDMUNDS, H. C., M.R.C.S., L.R.C.P., Junior House Anæsthetist; WILES, M. A., M.R.C.S., L.R.C.P., Junior House Surgeon to the Throat Department; SEAH, E. K., M.R.C.S., L.R.C.P., Assistant Casualty Officer; ALLEN, B. L., L.D.S., Second Dental House Surgeon.

Vacancies.

For further information refer to the advertisement columns.

Blackburn County Borough.—Asst. M.O.H. and Asst. Sch. M.O. £600.

Blackburn Union Institution and Infirmary.—Res. Asst. M.O. £200.

Cambridge, Addenbrooke's Hospital.—H.S. Also H.P. Each at rate of £130.

Chelsea Hospital for Women, Arthur-street, S.W.—Sen. and Jun. H.S.'s at rate of £120 and £100 per annum respectively.

Essex Administrative County.—Sen. Clin. Tuberc. O. £750.

Hoo Rural District.—Part-time M.O.H. £60.

Hospital for Sick Children, Great Ormond-street, W.C.—H.S. Also H.P. Each at rate of £50.

Hove Hospital, Sackville-road.—Res. M.O. £175.

Lindsey County Council.—Locum Tenens Asst. Sch. and Tuberc. O. at rate of £600.

London Hospital.—Head of Children's Dept.

Patna, India, Medical College.—Prof. of Pharmacology, Prof. of Anatomy, and Prof. of Physiology. Each Rs.1200 per mensem.

Queen Mary's Hospital for the East End, Stratford, E.—H.P.'s and H.S.'s, &c.

Queen's Hospital for Children, Hackney-road, Bethnal Green, E.—Asst. S.

Royal Free Hospital, Gray's Inn-road, W.C.—Asst. Cas. O., H.P. Also two H.S.'s.

Royal Northern Hospital, Holloway, N.—Two Asst. Surg. O.'s. Each £75.

St. Bartholomew's Hospital Medical College.—Lecturer on Pharmacology and Therapeutics.

Salford Royal Hospital.—H.S., H.S. to Gynæcological, &c., Depts., and H.P. Each at rate of £125.

Sheffield, Jessop Hospital for Women.—Asst. H.S. at rate of £100.

Sheffield Royal Hospital.—Res. Surg. O. £200

South-Eastern Hospital for Children, Sydenham.—Asst. P.

South London Hospital for Women, South Side, Clapham Common, S.W.—Asst. P.

Surrey County Council.—Asst. M.O.'s in Public Health Dept. £600.

Wandle Valley Joint Hospital Board Isolation Hospital, Beddington Corner, Mitcham Junction.—Res. M.O. £400.

West Bromwich Union Infirmary, Hallam-street.—Sen. and Jun. R.M.O. £300 and £250 respectively.

West London Hospital, Hammersmith-road, W.—H.P., H.S., Aural H.S., and Res. Cas. O. Each at rate of £100.

Births, Marriages, and Deaths.

BIRTHS.

FICKLING.—On May 23rd, the wife of E. L. Fickling, M.R.C.S., L.R.C.P., L.D.S., of Brook-street, W., of a daughter.

GREENLEES.—On May 17th, at Buckingham-terrace, Glasgow, W.C., the wife of James R. C. Greenlees, D.S.O., M.B., B.Ch., of a daughter.

HARVEY-WILLIAMS.—On May 21st, at Lisnamoe, Hitchin, Herts, the wife of Robert Harvey-Williams, F.R.C.S. Edin., of a son.

MACARTHUR.—On May 17th, at Wigmore-street, W., the wife of Bt. Lieut.-Colonel W. P. MacArthur, D.S.O., R.A.M.C., of a son.

DEATHS.

BATE.—On May 21st, at Surbiton, Edwin Beresford Bate, M.B. T.C.D.

SOUTTER.—On May 16th, Dr. Mansfield Knox Soutter, of Avenell-road, Highbury.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

THE AWKWARD AGE.*

By W. A. Potts, M.A., M.D. Edin.,
PSYCHOLOGICAL EXPERT TO THE BIRMINGHAM JUSTICES; HON. PHYSICIAN TO THE TAVISTOCK CLINIC FOR FUNCTIONAL NERVOUS DISEASE.

The awkward age is the period from 14 to 21 years of age. There is no real character at birth, but it may be fully developed at 21. Some consider the character fully developed by 18, but we shall be nearer the mark if we say character growth should be completed at 21 in the young woman and 25 in the man. As a matter of fact, character growth has never gone its full distance except in the case of that rare person, the perfectly normal individual, whom no one has yet seen. We are all in our psychological age or character development years behind our chronological age. If you do not agree you should think very carefully about some of your adult relations or friends whom you know best. It is impossible for most of us to see it in ourselves as we are too close to what we want to see, but it is not so difficult sometimes in regard to others, particularly men; women, especially those who have a strong maternal instinct, often develop psychologically beyond their male companions. It is a common observation of many wives that their husbands remain just big boys. This is not a delusion but a true observation. The boys may be successful in their business or profession and lead satisfactory lives, for they often have been well trained, but remain just big school-boys, a source of unconscious disappointment to their better developed mates, who hoped, and often still believe, they have got a strong sensible man. If you doubt this, you should observe a group of men in the army, in their clubs, and at their sports, especially at golf, which is one of the most serious businesses of life. And if you still doubt you should compare men with women in their clubs, or better still in their debating societies, or best of all in their own homes, where their work never ends, but where there must always be peace when father returns from his arduous work in the office.

The First Stage of Life.

When the child is born it is at first as much a part of the mother as it was before birth; during the earliest years of life it cannot exist apart from the mother, who herself, at first out of herself provides its food, cleans it, keeps it warm, and regulates its whole life. If the mother dies at this stage the baby inevitably dies too, unless some substitute takes the mother's place. This early time in life is so simple and easy for the child, who has every want supplied, if not anticipated, that it is often spoken of as Paradise. It is the stage of life to which we all unconsciously yearn to return. What does the married man in financial difficulties occasionally do but think how he missed his chance with the plain girl with the dollars, who was so obviously interested in him, when he foolishly threw in his lot with his more capable, but penniless, wife. In a similar way the young married woman who has had a tiff with her husband suddenly remembers that she has quite forgotten her father, who is not being properly cared for in the old home—dear old father, who was always so kind and understanding, who often wrote cheques before he was asked, and could never refuse his favourite child a new frock; then she runs away for the week-end from reality and her husband, back to her indulgent old father—back to Paradise.

The Maternal Instinct.

I have already indicated the great value attached to the maternal instinct, the most beautiful of all instincts. The tragedy for the mother is that the time for its full exercise is so very short; in the early years of the child's life she must begin to teach it to grow away from her and gradually to become independent. The curve denoting the degree of attachment to the mother falls rapidly; by 7, one of the many crises of life, it should be diminished. About 12 the mother sees her boy transfer his main interest and affection from her to his father for the next year or two; if the child is a girl the mother is left in the lurch even earlier, for at 10 the girl's emotions should be centred round her school companions. I cannot do more than briefly indicate this emotional development; those of you who are specially interested will find it well described in Dr. H. Crichton-Miller's book, "The New Psychology and the Parent." Much of the child's future success and happiness depends on wise handling by the mother during this difficult time. She must have broad views and look into the future. If she does guide the child wisely, he may—indeed, must—leave her for a time, but will come back when he has really grown up, honouring her as the wisest, kindest, and best guide, counsellor, and friend he ever had. The mother must watch that she never selfishly clutches her child after 7, and worst of all between 14 and 21, with that strangle-hold so fatal to individual development. That hold, far too common, is a heavy handicap for the child till he has fought free of it, which he should not have to do. Till he is free he cannot make the best of his talents, and will not go to his mate, when he marries, prepared to be the master in his own house. One difficulty is that the child both wants to get away and develop, but also unwittingly clings to the mother; all children are afraid of life and of facing the great adventure it involves. From our earliest days fear, especially of the unknown, is a bigger factor in our mental horizon than most of us would like to admit.

Pleasures connected with children are among the purest and best in life. But we can only have those pleasures for a short time. Family life is the ideal way of training the child for life, but we must remember that after 10 the child must leave the parents more and more; if they hold him back, if mother still expects to share all his school experiences, he will never develop esprit de corps, or keenness for his house and school. Still less can he appreciate patriotism, or grow beyond that, so that he can say with Edith Cavell, Patriotism is not enough; and accept the League of Nations and all that connotes. The mistake of so many parents is, not that they over-estimate the importance of home and family life, but that they fall into the error of thinking their family life must go on for ever, forgetting that the family life should only be an epoch in their own lives, and still more only a short period in the lives of their children, who at 21 should be adult individuals, preparing to establish their own homes and to train their own families. The mother means to be so unselfish, and yet it is largely selfishness that makes her afraid her boy is too delicate or too generous or kind-hearted to be trusted alone in this wicked world.

Some Cases in Point.

Just one or two instances from actual life. A middle-aged woman, who had never met her fate, dreamt that she was having breakfast with her father and her sisters. They were in the dining-room having a really good meal, while her mother, looking old and ill, was running in and out of the kitchen, cooking all kinds of delicacies for her husband and children and waiting on them all. This dream was a great surprise to her, because her mother had never done such a thing in her life. Actually, the mother had been for years a chronic invalid, waited upon by a devoted husband and children, and had ultimately died after a long illness. To some, perhaps, a beautiful picture of devotion, but the irony of it is that the daughters have never married, and one has had a nervous breakdown. The one who dreamt the dream has some chance, for the mother looking old and ill in the dream means not the actual mother, but that the undue attachment to the mother is being realised at last as a sickly and ageing influence, whose spell may soon be broken.

One of the worst examples I ever saw was a healthy middle-aged woman who was wearing out both her husband and a kind doctor by so-called heart attacks; she actually took her 16-year-old daughter away from a boarding school to come home and wait on her; the girl was not allowed to go to dances because her mother had panics that she would have an attack whilst her daughter was out. The mother had the opportunity of treatment for her nerves, but very soon gave it up, the unrecognised desire to remain in the centre of the picture being too strong.

A young woman, a typist, was once brought to me by her mother because she was becoming unduly self-centred and unsocial. The father was dead, the only other child, a boy, was doing well in the colonies. Mother and daughter lived together. The strangle-hold on the latter had nearly crushed the daughter's ability and independence. She must have shown possibilities at one time, because about a year before the head of a firm where she had been employed sent for her to say he was going to enlarge the business and wanted to have a much bigger office and office staff; he wanted her to come back and be the head of this new office. She refused because she felt the responsibility would be too great. When she would not undertake the work the man let the scheme drop; so I told her she must write to him, say she had thought it over and would take up the post if he still wished it. But she never could bring herself to write the letter or to go and see that man; she said she was satisfied with her present post and salary and would stick to them. I explained to her that that was impossible, because we never can remain stationary in life, but must always be advancing or regressing, and told her that unless she roused herself she would get a polite note one day to say that in view of increased costs her salary must be reduced; she then said, "That little note has already come."

In contrast to such a downward career I could tell you of other young men and women who, sometimes in opposition to father's and mother's wishes, despite the advice of friends, have left the easy job with an assured pension to take the post, little or no better for the moment, in which they visualised possibilities.

---

* Being a lecture given to the Birmingham branch of the Parents National Educational Union on March 9th, 1925.

Duties of the Father.

But you must not think that only the mother is to be blamed for failure in life; fathers are just as bad, and often worse. One, telling me about his family, said he had a beautiful relationship with his 17-year-old daughter; after she had gone to bed at night he would go up and sit on her bed; she would put her arms round his neck and hug him and say, "Daddy, I love you so much—I shall never want to get married, I shall always stay at home and cherish you." He was surprised when I told him it was not good relationship, and that he must watch for an opportunity of saying to her: "If you really love me, you will look forward, and in every way prepare yourself for the time when you will have left home, and will send for me to lay in my arms your own little baby, the most wonderful treasure you ever had."

A bad case was a man of 50, a bachelor, supporting his sisters, who lived with him. His father had only a very small income. The whole family life centred in the father. Soon after the son had come of age he went one day and said to his father: "Father I have made up my mind I will never marry, but will work always to support my sisters." The father replied: "You dear boy, now I can die happy." It was all wrong. The man who can only earn very little has no right to let his daughters grow up unable to support themselves. Fathers ought not to shelve their duties and pass them on to their sons. The drag on the son was such that he became more and more ineffective, and ultimately so useless that the firm to whom he had given devoted services for many years welcomed an opportunity of pensioning him off. In this case I am not prepared to say the trouble was all due to upbringing and environment. I did not see the man till he was 50, and for all I can tell he may never have had much inborn ability or strength. Environment in childhood and during the awkward age is very important, but we cannot ignore the influence of heredity too. A few lucky individuals are born so strong that the worst possible home environment cannot keep them back.

Another hopeless case was a middle-aged woman convicted of a criminal offence. She did her work conscientiously all day and in the evening went home to slave for a drunken father and an incompetent mother. When I was speaking to her about the various values in life she said: "I think the important Commandment is the Fifth." What is the Fifth Commandment? She replied: "Honour your parents and work for them as long as they live." This woman might have been helped years before, but it was then too late.

The Home Influence.

Many people do not realise how the father and mother influence develops in early childhood. The adolescent does not realise it either, though he may have a glimmering of understanding. A young woman was going to be married in a few weeks to a man who meant a great deal to her. Yet the nearer the marriage the more bad-tempered and deaf she became. There was only slight deafness; the greater part was due to her "nerves," as was also her temper. It transpired at the first interview that her fiancé had told her that though he would make other arrangements for the first year, after that his widowed mother must live with them. Here was the cause of the nerves. Finding that he had married sisters who were capable, if necessary, not only of housing the mother, but of keeping her in her place, I told her that she must tell the man it could not be. "Must I really break off my engagement if he won't agree?" she said. I told her she must be prepared to do so, though probably it would never be necessary. Fortunately it was not. The bachelor who wants to propose but cannot, the man who breaks off his engagement, perhaps shortly before the date fixed for the wedding, and also the young woman who cannot accept the right man, or goes on philandering with the wrong one, are often still fettered by parental chains.

The first idea I want to put before you is that home influence, like another force to be considered directly, is meant to be constructive; if it is misdirected and abused, then it becomes not constructive but hopelessly destructive. When a great Englishman died a few years ago much was written about his beautiful devotion to his mother, whom he either visited or wrote to every day of his life. Some of us thought his life would have been more noble if he had been faithful to his wife and a little less devoted to his mother. The Don Juan type is often an undeveloped person, who has been so spoilt that he is always looking for mere gratification, and cannot reach any large conception of life and duty. He finds no peace in life because he is not aiming at a satisfactory and harmonious combination of all the urges in him.

Development of the Individual.

The aim of training and education is to develop individuals, men and women, who can stand alone and be effective for life. When we speak of being individual there comes to some minds the idea of selfishness. But real individuality implies not selfishness, but the highest altruistic motives. Confusion arises because some think individuality means individualism. Now, individualism is merely the reaction to collectivism; if people are coerced beyond a certain point, they kick over the traces altogether. Individualism is seen at its best—or worst—in America, where as soon as prohibition was established, young men and women, so it is said, were brought home drunk from dances; they did not drink to excess because they really wanted excess, still less because they believed it would do them good and help their development, but as a reaction to extreme collectivism, which was seeking to regulate every detail of life. Individuation, on the other hand, is a word employed by Dr. Jung, of Zurich, to describe the result of the individual being encouraged, helped, and left free to develop all that is in him, so that he can become an effective individual, making the best of himself and also realising he has a duty to humanity. "Since the individual is not only a single separate being, but by his very existence, also presupposes a collective relationship, individuation must lead to a more intensive and universal collective solidarity, and not to mere isolation." Before individuation can be taken for a goal, the educational aim of adaptation to the necessary minimum of collective standards must first be obtained. It has been well said that: "A plant which is brought to the fullest possible unfolding of its particular character must first of all be able to grow in the soil wherein it is planted."

Enforcement of Discipline.

Just a word about discipline and how far the parents should combine to teach it. Discipline must be enforced from the first day of life, chiefly by the mother, but the father must do his part and support the mother in every possible way. Till 7 years or thereabouts the parents should represent a single directing force to the child; between 7 and 14 the parents should gradually cease to show the child an uninterrupted front, for the school discipline is coming in; the mother is still the chief teacher, but in some matters the father should also teach, either separately or in a manner supplementary to the mother. But when the awkward age is reached, if the parents have omitted to enforce discipline before, it is too late; they must stand by and watch the boy they neglected to train at the right time learning the discipline of life in a more unpleasant and painful way by being bullied at school or ragged in the army or at the university or in the office. It is not right after 14 for the parents to combine to bend the child they have allowed to get out of hand. He will instinctively regard their union as an unholy alliance which may drive him into unsatisfactory paths.

After 14 the difference between father and mother must be clearly shown, for during the awkward age the child must gradually learn through his parents that the two sexes have different ideals, and look at life from different angles. He should find out by observing them that it is more helpful to discuss some subjects with a man, others with the opposite sex, and that often the most valuable process is to hear the ideas of both and differentiate between them. In this way he or she comes to his mate, knowing that the two sexes never can look at life from the same point of view, and dimly realising in any particular circumstances which outlook will help the most.

Conclusion.

[Dr. Potts then wisely discussed modern views on sex instinct, and concluded:] We must recognise there are many forms of sex expression. Ordinary social intercourse is one, and dancing is another, of great value as an outlet in the awkward age. Barrack or monastic life too often means running away from life and its problems; if so, it is no help, but often leads to serious complications. We ought to do all we can to make early marriage possible. The father should help his son to marry early, and not present the pitiable spectacle of a manager past his best, still directing the business, which is going down-hill, while the son, who could do more effective work, has to remain a subordinate, and year after year tell his girl that father still hangs on, and so makes marriage for them impossible. In this connexion the choice of a business or profession is most important. Parents often say there is no definite taste; this frequently means that the boy has a call to some work such as a minister, or farmer, an actor or a soldier, which the parents either despise as a calling or regard as too unremunerative for their wonderful offspring. Sometimes there does seem to be no actual wish; then it may be wisest to adopt the father's profession or business, because the chances are that some ability for that will be inherited. Even if nothing special appeals a start must always be made; the policy of waiting to see what turns up is bad. If by any chance the boy or girl starts on the wrong career it will then be easier for them to see the real call.

If the life's work does not satisfy it must either be changed or some hobby of value made an important item in the life. There is now more than one way of testing aptitude for business or profession; in difficult cases these might be employed.

Sometimes parents, who rightly wish their daughter to get married, hesitate to let her do anything definite with a view to sublimation, still less take up a profession or business, because they think it will diminish her chance of matrimony. This is a mistake, because the developed woman, who has made the best of herself, is always more attractive to a real man who wants a companion for life and not a spoilt child.

In conclusion, I would suggest to you that the idea to put before your children is that life is a great and glorious adventure; if we regard it as that, and face our problems and think them out, and also get all the understanding we can, then, though passing through life may involve many hardships and many difficulties, yet the goal at which we aim is worth all the toil and dangers.

ENDOCRINE TREATMENT OF ECTOPIA TESTIS.

To the Editor of THE LANCET.

SIR,—One frequently comes up against a case of ectopia testis in practice where the parents are very desirous of avoiding surgical assistance. During the past few years I have prescribed "mixed glands" tablets (B.W. & Co.) (male), one nightly, in such cases, and it appears to me as if the descent takes place sooner than if left to nature. The last case I have had was a small undeveloped boy of 11, who took one tablet nightly for two years and whose right testicle finally took up its scrotal position three months ago. Is the endocrine treatment the only resort apart from surgical measures?

I am, Sir, yours faithfully,

JOHN WISHART, M.D., D.Sc.

Newcastle-upon-Tyne, May 12th, 1925.

A PECULIAR CASE OF "ALBINISM."

To the Editor of THE LANCET.

SIR,—I have seen in your issue of March 14th, recently received, an extract from a writer in *Man*, saying that he considers there is a local tendency to albinism, and that he has never seen an elderly adult case of albinism. In the town of Ilorin there are over 80,000 inhabitants, and without any search I could show you three elderly adult albinos, and I have no doubt there are more. The local belief is that they have been made so through the good offices of the Goddess of Agriculture, who also is supposed to frame the human body in the womb. The woman to whom such a child is born is very pleased, and carries it round on her back, and receives the alms of the inhabitants, as she walks through the town. There is no suggestion of any part played by the white man, and the matter is satisfactorily explained by the theory mentioned. The adults take their share in the business if females, but the males depend on the charity of the people, or in rare instances they act as buyers of cattle. The people of Nigeria believe in many more deities than the Gold Coast people, and this is probably the cause of the different opinions in countries which are so near to each other.—I am, Sir, yours faithfully,

J. R. C. STEPHENS,

Medical Officer, West African Medical Service.

Ilorin, Northern Nigeria, May 7th, 1925.

PERFORMANCE TESTS OF INTELLIGENCE.

IT is now well recognised that the scales of intelligence tests most generally used—those, that is, of the Binet type—are liable to yield fallacious results in the case of those whose command of words is restricted but who may have considerable capacity for industrial occupations. They are also almost entirely inapplicable to such special classes as the blind, the deaf, and certain speech defectives. To supply what is lacking in the Binet scales many investigators, particularly in America, have devised performance tests, which are intended, of course, to be not merely tests of manual dexterity, but tests of intelligence applied in this direction. These scales of performance tests, in which each test is designed to elicit a different quality of intelligence, have obtained some note, Pintner and Paterson's (1917), Dearborn's (1923), and that used in the United States army in war-time. In a report just issued by the Industrial Fatigue Research Board, Miss Frances Gaw, B.A., puts forward a new scale. It contains no new tests, a selection having simply been made from already existing sources. Nearly half of them are drawn from Pintner and Paterson's scale: Healy's already well-known picture and construction tests are included, as also the even better-known Porteus maze test. The scale has been standardised by an experimental trial upon the children of three L.C.C. elementary schools, but as all the tests are not applicable to all ages, some being too easy for the older children, others too difficult for the younger, the mental ages and intelligence quotients obtained by their use can scarcely be regarded as thoroughly dependable. Even, however, in this tentative form the scale will form a valuable addition to the certifying officer's armamentarium of tests. His only difficulty may be the very practical one of finding time to apply them to his subjects.

"HYGIENE JINGLES."

Dr. R. C. Everitt Atkinson, who is Commissioner of Public Health for Western Australia, has incorporated the rudimentary principles of hygiene and sanitation in the form of verse (Hospital Electrical and Radium, Ltd., Adelaide, pp. 48). Young children in Australian schools apparently spend ample time learning poetry, and the Commissioner jealously claims some of this time for the initiation in personal hygiene and preventive medicine which will give the child an accurately set health compass for life. To those who incline to scoff at his endeavour he replies that they might find it difficult themselves to write in verse elegantly of a rubbish bin, tragically of a mosquito, feelingly of a fly. Dr. Atkinson has really succeeded in writing some jingles which children are likely to read, and his little book is worthy of more attractive format and a competent illustrator.

PYOTROPIN FOR LUPUS.

IN the *Deutsche Medizinische Wochenschrift* for April 3rd Dr. Axmann (Erfurt) describes a new treatment for lupus with a preparation called pyotropin, which consists of a liquid and an ointment. The former contains a sediment of chalk with potassium phenolate and a little free carbolic acid in watery solution. In the ointment there are equal parts of salicylic acid and salicylate of soda with glycerine and sugar added to the base. The trial of pyotropin began in the early part of 1924, and cases which had proved intractable to caustics and various forms of light—those, in fact, in whom the prognosis appeared hopeless—were first selected. The average length of treatment was six weeks. Mucous membrane lesions (nose, ear, eye) appeared to yield with particular ease to the applications. On the whole, the author is satisfied that pyotropin is more efficacious in destroying lupus nodules, and at the same time simpler, cheaper, and safer to apply than all other remedies hitherto recommended. Pyotropin is stated to be non-poisonous. All the cases were treated as out-patients, so that the loss of time entailed was very small. Eighteen actual cases are reported in detail, and the results, according to Axmann, were flat, healthy-looking scars without residual or recurrent nodules, and comparable from the cosmetic point of view to the best Finsen-lamp effects. The method of application is not stated, nor is the question of pain discussed.

STANDARD SPELLING.

THE twenty-seventh edition has just appeared of the "Rules for Compositors and Readers at the University Press, Oxford," first issued by the late Mr. Horace Hart, M.A., Printer to the University, in April, 1893. The present edition, with spellings revised by Sir James Murray and Mr. Henry Bradley, is published by Mr. Humphrey Milford at 2*s.*, and contains 135 pages. It is a most entertaining little book for any who are interested in the histology of printing. Punctuation is a frequent source of delightful or perplexing ambiguity. The story is quoted of Sheridan's apology to a Parliamentary opponent which was printed thus: "Mr. Speaker I said the honourable Member was a liar it is true and I am sorry for it." In this case it would not have been fair, as is usually done, to put the responsibility of punctuation on the compositor. Accuracy is carried to a point unimagined by those who only roughly scan the printed page. Nine or ten pages on alternative or difficult spellings contain distinctions which may be unfamiliar even to the practised writer. Who, for instance, would distinguish between the three forms of a familiar word (1) bogey (in golf): (2) bogie (a truck); (3) bogy (an apparition): and even the University Press fails to give help as to how the plurals should be formed. Some words in the list recall literary tussles: Mr. W. E. Gladstone, at first a champion of the spelling "forego," had ultimately to yield to the authority of Skeat and Sir James Murray, and frankly to admit "I give in." Especially agreeable to medical writers will be the list of spellings on pp. 25–32 for use in medical works, on many of which a difference of opinion no doubt is justified; but the mere fact of having a precise form set out will stimulate the writer to accuracy, either in agreement or disagreement. To those correcting proofs for the first time, p. 124 will appeal.

Relationship
BETWEEN
PNEUMONIA INCIDENCE AND CLIMATE IN INDIA.

BY SIR LEONARD ROGERS, C.I.E., M.D.,
F.R.C.P. LOND., F.R.S.,
LIEUTENANT-COLONEL, I.M.S. (RET.).

IN recent papers I have shown a close relationship between leprosy incidence and rainfall in India,[1] and between pulmonary tuberculosis and humidity and rain-bearing winds [2]; in the present communication I propose to deal with pneumonia on similar lines. Over a decade ago [3, 4] I pointed out that phthisis and primary pneumonia in Calcutta were each responsible for about one-sixth of the total deaths in the Calcutta Medical College Hospital, as shown by an analysis of several thousand post-mortems, each causing a much higher mortality than any of the so-called tropical diseases; in my recent Finlayson lectures [5] I pointed out that the Calcutta vital statistics showed a still higher mortality from these two lung diseases, so their importance in India can scarcely be exaggerated. Moreover, my 20 years' post-mortem experience in Calcutta revealed that, except during a few months of the recent influenza pandemic, broncho-pneumonia was very rare, and the greatly predominating lobar form was essentially a disease of the prime of life, 70 per cent. having occurred between the ages of 21 and 40, and 97·3 per cent. between 11 and 60; so it may safely be assumed that among the jail population of over one and a half millions, with which I shall be dealing in this paper, among whom there are no children and few old people, a very great majority of the pneumonia cases were of the lobar form; for the 15 years' data from 1896 to 1910, from which the incidence shown in Fig. 1 are taken, are after the influenza epidemic of the early 'nineties and before the recent pandemic, over one-seventh of the total jail mortality during the period under review having been due to pneumonia, or about equal to the phthisis death-rate, and only exceeded by that from dysenteries. As the jail populations are under I.M.S. officers and post-mortems are made on fatal cases, they afford ideal data for studying the true incidence of pneumonia and other diseases in different parts of India.

INCIDENCE OF PNEUMONIA IN INDIA.

It has long been known that pneumonia is very prevalent, occasionally almost in epidemic form, in the North-West part of India, which has a much drier climate than the rest of India, while the extreme variations in rainfall, temperature, and degree of humidity in different areas of this vast country constitute India an ideal country for studying the influence of climate on disease incidence; for the annual reports of the Sanitary Commissioner, with the Government of India record the rates per mille for a number of divisions, which were originally selected many years ago, through consultation between the medical and meteorological authorities, as representative of the varying climatic conditions of India. As the rates per mille for pneumonia are usually very similar year by year in the same area, the average figures I have worked out from 15 consecutive years may safely be relied on as sufficient for comparative purposes, and the figures are given in the accompanying table and also entered in Fig. 1, which is shaded according to the scale shown in it, from which it will be seen that the distribution of the high, intermediate, and low rates are very clear-cut; and the difference between the lowest and highest rate is more than a ten-fold one; presenting a striking picture, lending itself admirably for comparison with the meteorological data for the various parts of the country.

A brief description of the incidence of the disease will suffice, the numbers in brackets after the name of an area representing its number in Fig. 1. The highest rate of just over 50 per mille is found in the Lower Indus Valley, or Sinde (7b) in the North-West of India; the adjacent North Indus Valley (7a) and Gujerat (8a) areas show the next highest rates of over 25 per mille; these three areas are shaded uniformly dark in the map, while Baluchistan still further west has the highest pneumonia rate in the Indian Army, but is left unshaded as no jail figures are available for it. The next highest rates of 20 to 25 per mille are found in the two divisions immediately to the east of the areas of highest incidence just dealt with—namely, the Upper Sub-Himalayan (6) and Central India (8b), shaded with crossed lines; to the east and south of which there is a remarkable drop to below 15 per mille, or approximately the average rate for all India of 13·3 per mille, no intermediate figures of 15 to 20 being found, thus marking off the north-west area of exceptionally high incidence very clearly.

The areas of average incidence, 10 to 15 per mille, are shaded with single horizontal lines, and include the Central Provinces (9a), the Gangetic Plain and Chota Nagpur (5), Bengal and Orissa (4) and North-East Madras (11c) forming a solid block of the North-East of India proper, with the exception of Assam and Upper Burma. The remaining divisions still further south and east show rates below the normal, including Assam (3), the Deccan and Berar (9b), the Western Coast (10), and Central Madras (11a) with rates between 7·5 and 10 per mille; and the extreme south-east divisions of Burma Coast (1), Burma Inland (2), and South-East Madras (11b) with the very low rates of under 7·5 per mille; a steady decline from the north-west to the south-east being thus clearly evident, which must have some definite cause.

SEASONAL DISTRIBUTION OF PNEUMONIA.

We next require to know the incidence of pneumonia in the three very definite seasons of the year; the four dry cold months of November to February, the four hot dry months from March to June, during the last week or two of which the monsoon begins to spread over India, and the four wet equable months of July to October, during the last of which the monsoon gradually withdraws from Northern and Central India, and the comparatively feeble north-east monsoon becomes established over the south-east portions of the peninsula (11a and 11b). The table gives the percentages of the total 14,266 cases of each of these equal periods of time for every division, which would give an average of 33·3 per cent. for each season; the figures bring out the following interesting points. The total cases show the highest incidence of

45 per cent. in the four dry cold weather months, an approximately average incidence of 31 per cent. in the hot dry season with wide diurnal variations of temperature, especially during the occasional rain storms, and the low rate of 24 per cent. in the four warm equable rainy months. Turning to the figures for the different divisions, we find the cold weather incidence much below that of all India in just those areas in which the annual rate per mille is lowest—Burma, Assam, and Southern India; the percentages are about the average in Bengal, the Gangetic Valley, and the Central Provinces, with average annual pneumonia rates; but the cold weather percentages are in excess in the Upper Sub-Himalayan and Indus Valley divisions, where the highest pneumonia rates occur, the greatest proportion of 60 per cent., or nearly double the average, being met with in the South Indus Valley with by far the highest pneumonia incidence. It is therefore evident that we must look to the cold weather climatological conditions to furnish the clue to the excessive prevalence of pneumonia in North-West India and examine them in the two coldest months of the year, December and January, with the highest number of pneumonia cases, when they show 50 per cent. excess of the average monthly rates for the whole of India, and up to 100 per cent. excess in the high incidence north-west divisions.

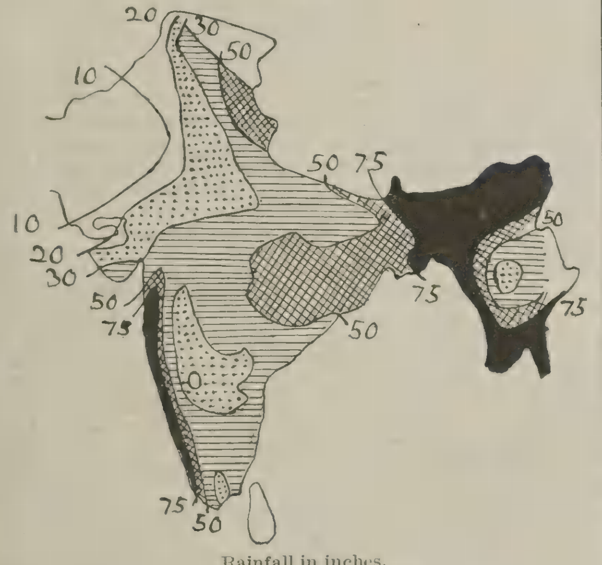
CLIMATOLOGICAL CONDITIONS INFLUENCING PNEUMONIA DISTRIBUTION.

Rainfall.—Fig. 2 shows the distribution in inches of the annual rainfall of India, from which it at once appears that the high pneumonia north-west area has the most scanty rainfall, but as the monsoon period shows a very low proportion of pneumonia in these divisions, the actual amount of rain does not appear to have much direct effect on the incidence of the disease.

Humidity.—The same high pneumonic area also has the lowest absolute humidity, as compared with other divisions, of 0·800 in the rainy season, as was illustrated in Map 1 of my recent paper on Tuberculosis Incidence and Climate in India,[2] but the study of this factor during the maximal pneumonia cold weather is of far greater importance, and consequently Fig. 3 shows the January absolute humidity, as measured by the mean daily aqueous vapour pressure, when the lowest readings of 0·300 and less are limited to precisely the north-west area of high pneumonic incidence of over 20 per mille, the lowest rate in India at any season of the year of 0·250 and under, indicating an excessively dry climate, being met with in the extreme north-west in the divisions with over 25 per mille of pneumonia. Moreover, the cold weather humidity steadily increases with the decrease in the pneumonic rate as we proceed east and south, to reach its highest readings in the areas of lowest pneumonia incidence in South-East Madras and Lower Burma; so the cold weather humidity appears to be an important factor to be considered in any explanation of the incidence of pneumonia in India, for the hot weather annual humidity in India shows a very similar relative distribution to the above described cold weather readings, that is during the seasons when over 75 per cent. of the pneumonia cases occur, and differs but slightly in the monsoon months of minimum pneumonia prevalence.

Cold Weather Minimum Temperatures.—I now turn to the temperature conditions during the maximal pneumonia cold season, which are illustrated in Figs. 4. and 5. Firstly, Fig. 5 illustrates the absolute minimum temperatures in January, with the lowest readings and slightly the highest number of cases of pneumonia, while the temperature distribution in December is almost exactly similar. Once more it is quite clear that all the highest pneumonia rates occur in the coldest north-west divisions, with a minimum temperature of 35° F. or less, while the rates steadily diminish as we pass west and south into warmer areas; nearly all the average pneumonia rates are found in areas with minimum temperatures down to 45°, and the lowest incidence is in South-East Madras and Lower Burma with minimum temperatures of 50° and over. It is therefore clear that low minimum cold weather temperatures favour the prevalence of pneumonia in India and vice versa.

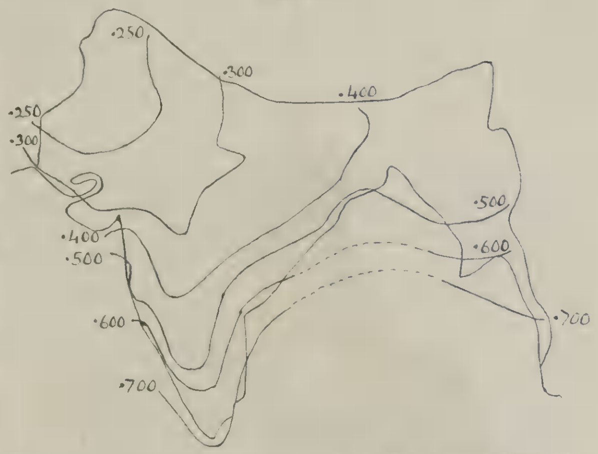
FIG. 2.



Rainfall in inches.

Diurnal Variations in the Winter Temperatures.—Fig. 4 also illustrates the still more important factor of the diurnal variations in the temperature in the month of December, when a great rise in the pneumonia cases takes place and the highest monthly number is recorded in the areas of high incidence, the cause of which I desire to elucidate; January has a closely similar temperature and pneumonia distribution. Once more a glance at the maps shows a most remarkable coincidence between the north-west areas with the highest diurnal variations of temperature of 30° and upwards in the cold season, and of the greatest pneumonia incidence; the next highest diurnal temperature variation of 25° and over covers nearly all the other divisions with about the average pneumonia incidence. On the contrary, the areas of rather low pneumonia have moderate diurnal variations of temperature, and the very low pneumonia areas of South-East Madras and Lower Burma are precisely those with the least diurnal variations of temperature in the cold months and also in the hot weather season. Moreover, in the rainy season of minimal pneumonia rates in all India the diurnal variations in India are much less than at any other time of the year, very rarely exceeding 20° during the monsoon months except in the extreme North-West of India, which the rains scarcely affect. We may therefore conclude that a great diurnal variation of temperature, combined with a low minimum in the cold season, together with a very low degree of humidity, constitute the principal climatological conditions associated with an excessive incidence of pneumonia; precisely the opposite conditions hold with regard to the lowest prevalence, and intermediate readings coincide with moderate occurrence of the disease.

FIG. 3.

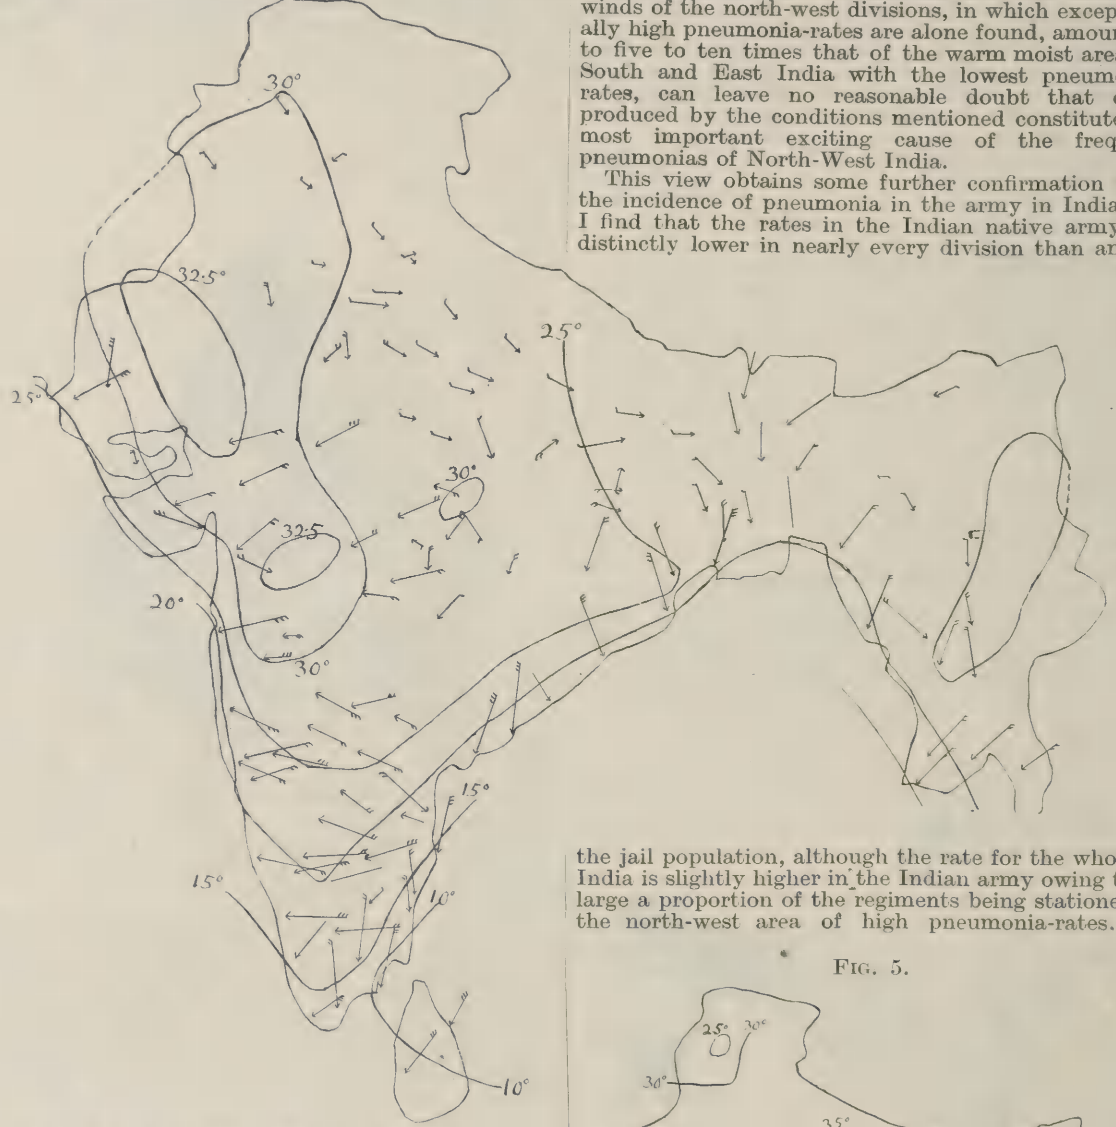


Absolute humidity or mean aqueous vapour pressure in January.

Direction of the Winds.—One other influencing factor is also illustrated in Fig. 4, in which the arrows represent the direction of the winds in the same month, December, their length being in proportion to the constancy, and the number of the feathers increase with their strength, the data in this and the other maps being taken from the Government Climatological Atlas of India, based on 20 years records. It will be observed that throughout the north of India the winter winds blow for the most part from the north to the south, south-east, or south-west; in the southern part of the peninsula, on the contrary, they mainly blow from the east from over the warm Bay of Bengal, and it is noteworthy that the cold north winds extend down only as far as the north-east portion of Madras (11c), exactly as far as an averagely high pneumonia-rate is found; south of this a very low incidence occurs with mainly warm east winds. Cold north winds, therefore, appear to be a further factor favouring high pneumonia-rates.

Variations in Case Mortality.—In the last column of the table I have entered the case mortalities of the main areas, which bring out an interesting point; for all the high percentages of deaths occur among the cases of the warm humid divisions with a low incidence of pneumonia; 39 per cent. in the Burma coast area (1), 36 per cent. in Assam (3), 30 per cent. on the west coast (10), 29 per cent. in Burma Island (2), which is less humid than the others just mentioned, and 28·5 per cent. in Bengal and Orissa (4). On the contrary, the very dry cold areas, with high pneumonic incidence, have low or average case mortalities, so it would appear that a dry climate is favourable and a humid one unfavourable to the progress of the disease. Unfortunately, only the monthly numbers of cases are recorded and not the death-rates, so I have not been able to ascertain if the case mortality from pneumonia is higher in the rainy than in the dry seasons of the year; it would be of interest if this could be ascertained.

Fig. 4.



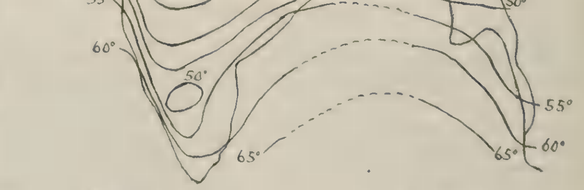
Diurnal range of temperature and winds in December.

Explanation of the Recorded Data.

In my long pathological experience in Calcutta lobar pneumonia was invariably due to the pneumococcus, and R. H. Malone has recently reported[6] a serological examination of 106 strains obtained in North-West India, and found 28·3 per cent. of type I., 17 per cent. type II., 7·5 per cent. type III., and 47·2 per cent. of the unclassified type IV., one-fourth of which belonged to a single subgroup. This class of organism has a widespread distribution in the throats of human beings, and the onset of pneumonia has for long been attributed to lowering of resistance to the organism by chills, &c. The facts brought forward in this paper are fully in accordance with that hypothesis, especially in view of the habit of Indians washing in the cold early mornings in the open, clothed only in their thin cotton dhoties, or loin cloths, which are allowed to dry on them. The low minimum temperatures, combined with a remarkably wide diurnal variation of temperature, exceptionally dry atmosphere resulting in cooling through rapid evaporation of any moisture, and the cold northerly winds of the north-west divisions, in which exceptionally high pneumonia-rates are alone found, amounting to five to ten times that of the warm moist areas of South and East India with the lowest pneumonic-rates, can leave no reasonable doubt that chills produced by the conditions mentioned constitute the most important exciting cause of the frequent pneumonias of North-West India.

This view obtains some further confirmation from the incidence of pneumonia in the army in India, for I find that the rates in the Indian native army are distinctly lower in nearly every division than among the jail population, although the rate for the whole of India is slightly higher in the Indian army owing to so large a proportion of the regiments being stationed in the north-west area of high pneumonia-rates. the Sepoys being better clothed than the jail population. Further, the British troops are better clothed and far better housed than the native troops—for the latter commonly wear only their own thin cotton

Fig. 5.



Absolute minimum temperature in January.

clothing when off duty as well as at their morning open-air ablutions—so it is noteworthy that the British army pneumonia-rate for the whole of India is only 4·03 per mille, against 13·57 in the Indian army, in spite of so many of the British troops being stationed in North-West India during the cold winter, and most of them go to the hills for much of the year, where the pneumonia-rate is also high. It is of interest to note that the pulmonary tuberculosis distribution is almost exactly the opposite of that of pneumonia—namely, in the warm humid monsoon-swept divisions as shown in my recent paper.[2]

The relationship of pneumonia to great diurnal variations of temperature with a low minimum is also in accordance with the well-known frequency of pneumonia in Egypt due to chills induced by the very rapid fall of temperature after sunset, and Dr. Andrew Balfour informs me that the same is true of the dry areas of the Sudan. Forewarned is forearmed, so if the evidence brought forward in this paper leads to the more general recognition of the danger of chills under such conditions, and the necessity of guarding against them, many valuable lives may be saved, and one of the most serious causes of mortality in the world may in some degree be mitigated.

SKIN TESTS,

ASTHMA AND IDIOSYNCRASY.

By F. G. CHANDLER, M.D. CAMB.,
F.R.C.P. LOND.,

PHYSICIAN, WITH CHARGE OF OUT-PATIENTS, CHARING CROSS HOSPITAL; PHYSICIAN, CITY OF LONDON HOSPITAL FOR DISEASES OF THE HEART AND LUNGS, VICTORIA PARK, E.

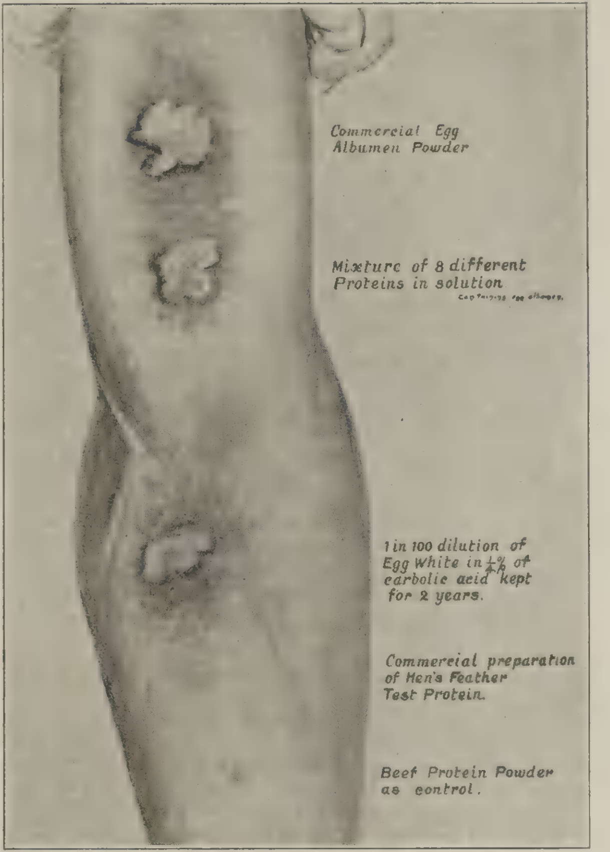
I BELIEVE that along the path of the study of idiosyncrasy great discoveries will be made. Certain obscure diseases which have hitherto defied convincing explanation may become elucidated. Under this denomination I would place asthma, migraine, recurrent urticaria, so-called essential œdema, perhaps cyclical vomiting, and other gastro-intestinal disturbances, eczema, and other skin diseases. There is no doubt that many skin eruptions are directly attributable to idiosyncrasy, and with some attacks of asthma the ætiological relationship seems as certain. It is necessary, however, to be critical, and not to be carried away by enthusiasm; for crazes in medicine are not creditable, and history contains too many examples.

The tests for discovering an unknown idiosyncrasy are so laborious, the chances of obtaining a truly positive reaction so precarious, the work and expense entailed in the preparation of suitable test substances so great, that the following points become of paramount importance: (1) Technique. (2) Confidence in the "activity" of the test substances. It is proposed to deal with these points and with the following:—The significance of the reaction. The therapeutic application of a proved idiosyncrasy. The efficacy of certain commercial test proteins.

Technique.

(*a*) *The Test Substance.*—If the test substance is in liquid form this is placed directly on the arm, which has previously been cleansed with ether. If in powder form a few drops of decinormal soda are placed on the arm and a few grains of the powder added to this. If dried on blotting-paper after the method of Freeman, a few drops of decinormal soda are used as above, the epidermis pierced in the manner to be described, and the square of blotting-paper placed on the soda solution. If the crude substance is to be used as a test, it can be ground up with decinormal soda and the test made with this. If desired it can first be shaken up with ether.

(*b*) *Method of Piercing the Epidermis.*—To ensure uniformity it is essential to have ocular evidence that the epidermis has been pierced. A mere scratch is unsatisfactory, as it is difficult to be certain that all parts of it are equally deep. I therefore use the following method. After placing the test substance on the arm as above a sharp needle is taken and the skin pricked very lightly and quickly with the point several times. In a few moments petechiæ appear, and these are clear evidence that the epidermis has been pierced, and each tested area may be made uniform. There is no pain if done carefully, and the method is therefore a good one for children.



Commercial Egg Albumen Powder
Mixture of 8 different Proteins in solution
Containing egg albumen.
1 in 100 dilution of Egg White in ¼% of carbolic acid kept for 2 years.
Commercial preparation of Hen's Feather Test Protein.
Beef Protein Powder as control.

Reactions in an individual extremely sensitive to hen's egg, duck's egg, and hen's feathers. Counting from above downwards: Reaction 1 was obtained from a few grains of commercial egg albumin. Reaction 2 was obtained from a solution of eight different proteins, the individual being sensitive to the egg protein only. Reaction 3 proves that a solution of egg-white in ¼ per cent. carbolic acid will retain its "activity" for at least two years. Reaction 4 shows the failure of a commercial preparation to give a convincing reaction. A Victoria Park preparation of hen's feather protein powder in decinormal NaOH produced a reaction as big as 1. Reaction 5 a control.

(*c*) *The Type of Reaction* is seen from the accompanying illustration. The reaction must be unequivocal—no self-deception must be possible. If there is a true idiosyncrasy the reaction will be a large one.

(*d*) *Method of Group Testing.*—It is clearly impossible to test all the individual proteins separately. Theoretically any bird, beast, or fish, plant, tree or flower, fruit, vegetable, or fungus, may contain the offending substance. It is obvious, therefore, that unless they are grouped in some way the task of testing is impracticable. Clinical considerations may enable us to exclude certain things. For example, if attacks of asthma occur nightly they are not likely to be due to turkey or grouse, and if they occur only occasionally it is improbable they are caused by hens' feathers or wheat. But even these exclusions will leave a very large number of things to be tested. Group testing is therefore imperative, and the best method of doing this has to be determined. Elegant preparations are offered by a few commercial firms, but some of these I have found inert. It appears that to be effective they must be of a certain strength. Some are easily prepared, others are not; and therefore fish and meat test proteins are apt to be more effective than animal hair preparations.

My own methods are as follows, and I believe them to be effective.
